We suggest a method for calculating scattering phase shifts and energies and widths of resonances which utilizes only eigenenergies obtained in variational calculations with oscillator basis and their dependence on oscillator basis spacing \( h\Omega \). We make use of simple expressions for the \( S\)-matrix at eigenstates of a finite (truncated) Hamiltonian matrix in the oscillator basis obtained in the HORSE (\( J\)-matrix) formalism of quantum scattering theory. The validity of the suggested approach is verified in calculations with model Woods–Saxon potentials and applied to calculations of \( na \) resonances and non-resonant scattering using the no-core shell model.

I. INTRODUCTION

To calculate energies of nuclear ground states and other bound states within various shell model approaches, one conventionally starts by calculating the \( h\Omega \)-dependence of the energy \( E_\nu(h\Omega) \) of the bound state \( \nu \) in some model space. The minimum of \( E_\nu(h\Omega) \) is correlated with the energy of the state \( \nu \). The convergence of calculations and accuracy of the energy prediction is estimated by comparing with the results obtained in neighboring model spaces. To improve the accuracy of theoretical predictions, various extrapolation techniques have been suggested recently [1–13] which make it possible to estimate the binding energies in the complete infinite shell-model basis space. The studies of extrapolations to the infinite model spaces reveal general trends of convergence patterns of shell model calculations.

Is it possible to study nuclear states in the continuum, low-energy scattering and resonant states in particular, in the shell model using bound state techniques? A conventional belief is that the energies of shell-model states in the continuum should be associated with the resonance energies. It was shown however in Ref. [14, 15] that the energies of shell-model states may appear well above the energies of resonant states, especially for broad resonances. Moreover, the analysis of Refs. [14, 15] clearly demonstrated that the shell model should also generate some states in a non-resonant nuclear continuum. The nuclear resonance properties can be studied in the Gamow shell model, including the \( ab\ initio \) no-core Gamow shell model (NCGSM) [16, 17]. Another option is to combine the shell model with resonating group method (RGM). An impressive progress in the description of various nuclear reactions was achieved by means of the combined no-core shell model/RGM (NCSM/RGM) approach [18–23]. Both NCGSM and NCSM/RGM complicate essentially the shell model calculations. Is it possible to get some information about unbound nuclear states directly from the results of calculations in NCSM or in other versions of the nuclear shell model without introducing additional Berggren basis states as in NCGSM or additional RGM calculations as in the NCSM/RGM approach?

The general behaviour of shell model eigenstates at positive energies (or just at the energies above various thresholds) is not well-studied and there is no well-established extrapolation technique to the infinite basis space for resonances. Generally, a complete study of the nuclear continuum can be performed by extending the nuclear shell model with the \( J\)-matrix formalism of scattering theory. The \( J\)-matrix formalism has been suggested in atomic physics [24, 25]. Later it was independently rediscovered in nuclear physics [26, 27] and was successfully used in shell-model applications [28]. The \( J\)-matrix approach utilizes diagonalization of the Hamiltonian in one of two bases: the so-called Laguerre basis that is of a particular interest for atomic physics applications and the oscillator basis that is appropriate for nuclear physics. The version of the \( J\)-matrix formalism with the oscillator basis is also sometimes referred to as an Algebraic Version of RGM [26] or as a HORSE (Harmonic Oscillator Representation of Scattering Equations) method [29] — we shall use the latter nomenclature in what follows.

We note that a direct implementation of the HORSE formalism in modern large-scale shell-model calculations is very complicated and unpractical: the HORSE method requires calculation of a huge number of eigenstates while modern shell-model codes usually utilize the Lanczos algorithm which provides only the few lowest Hamiltonian eigenstates. Furthermore, the HORSE method needs also the weight of the highest component of the wave function of each eigenstate which is usually obtained with a low precision. On the other hand, the HORSE formalism can be used for a simple calculation of the scattering phase shift or \( S\)-matrix at a single energy \( E_\nu(h\Omega) \) which is an eigenstate of the shell-model Hamiltonian. In this case, the HORSE phase shift calculation requires only the value of the energy \( E_\nu(h\Omega) \) and the basis parameters (the \( h\Omega \) value and the basis truncation). We shall refer to such a simplified approach as a Single State HORSE (SS-HORSE) method. Varying the shell-model parameter \( h\Omega \) and using results from a set of basis
spaces, we generate a variation of $E_r(\hbar \Omega)$ in some energy range and hence we can calculate the phase shifts in that energy range.

Calculations of scattering phase shifts at the eigenenergies of the Hamiltonian in the oscillator basis and obtaining the phase shift energy dependence by variation of basis parameters, was recently performed in Ref. [5] using another (not the HORSE) technique. A detailed study of scattering phase shifts at eigenenergies of the Hamiltonian in arbitrary finite $L^2$ basis was performed in Ref. [30]. This study was based on the theory of spectral shift functions introduced by I. M. Lifshitz nearly 70 years ago [31] and later forgotten by physicists though used up to now by mathematicians (see Ref. [30] and references therein).

Another method to obtain scattering phase shifts from bound state calculations in a harmonic oscillator basis features the use of an additional harmonic oscillator potential [32]. The method was demonstrated with nucleon-nucleon scattering where it reveals a challenge of needing a large basis to access the low-energy scattering region.

It is worth noting here that approximate resonant widths can be extracted from bound state approaches to many-body nuclear systems using a relation between the partial width in a specified breakup channel and an integral over the “interaction region” where all of the nucleons are close to each other. This method was described in detail in Ref. [33] where it was used to evaluate widths of resonances in light nuclei based on the variational Monte Carlo calculations. It has been used before in combination with other many-body approaches (see Ref. [33] for the list of respective references), in particular, it can be utilized within the nuclear shell model [34]. However this approach is applicable to narrow enough resonances only and is unable to provide information about non-resonant scattering.

In this contribution, we suggest a simpler and more powerful approach. We formulate below a method for calculating low-energy phase shifts and for extracting resonant energies $E_r$ and widths $\Gamma$ from the shell model results, or, generally, from results of any variational calculation with a finite oscillator basis. We apply the SS-HORSE formalism to calculate the $S$-matrix in the energy interval of variation of one of the Hamiltonian eigenenergies $E_r(\hbar \Omega)$ due to variation of $\hbar \Omega$ and truncation boundary of the Hamiltonian matrix. We use either a low-energy expansion of the $S$-matrix or express the $S$-matrix as a pole term plus slowly varying with energy background terms and fit the expansion parameters to describe the $S$-matrix behaviour in the above energy interval. The low-energy phase shifts $\delta_\ell$, the resonant energy $E_r$ and width $\Gamma$ appear as a result of this fit. We obtain relations describing the general behaviour of shell-model states associated with a resonance or with a non-resonant continuum as functions of $\hbar \Omega$ and truncation boundary of the Hamiltonian matrix. This approach is tested in calculations of phase shifts and resonance parameters of two-body scattering with model potential. Next we apply the SS-HORSE method to the calculation of resonances and of non-resonant continuum in the neutron-\(\alpha\) elastic scattering based on No-core Shell Model (NCSM) results obtained with the JISP16 $NN$ interaction [35, 36].

In our earlier study [37], we evaluated resonant energies $E_r$ and widths $\Gamma$ using the SS-HORSE and Breit–Wigner formula for the description of resonances. The Breit–Wigner formula describes the phase shifts and $S$-matrix only in the case of narrow resonances and only in a narrow energy interval in the vicinity of the resonance. As a result, the approach of Ref. [37] can be used only in rare cases when the eigenenergies of the truncated Hamiltonian are obtained very close to the resonant energy $E_r$ and cannot provide an accurate description of resonant parameters even in these rare cases. This drawback is eliminated in the current study.

We present here an ab initio study of the neutron-\(\alpha\) elastic scattering within the NCSM-SS-HORSE approach using the JISP16 $NN$ interaction which was shown [38] to provide a good description of $s$- and $p$-shell nuclei. Ab initio studies of the same reaction with various other modern inter-nucleon interactions were performed within Quantum Monte Carlo approach in Ref. [39] and within the NCSM/RGM in Refs. [23, 40–42].

The paper is organized as follows. We present in Section II the basic relations of the HORSE formalism, derive the SS-HORSE method and present all equations needed to calculate phase shifts, $S$-matrix and resonant parameters $E_r$ and $\Gamma$. The SS-HORSE approach to the calculation of resonant energy and width is verified in Section III using a two-body scattering with a model potential. Section IV is devoted to calculations of resonances in $\alpha$ scattering based on NCSM calculations of $^5$He with JISP16 $NN$ interaction. Conclusions are presented in Section V.

II. SS-HORSE APPROACH TO CALCULATION OF LOW-ENERGY SCATTERING AND RESONANT PARAMETERS

A. HORSE formalism

The $J$-matrix approach and HORSE in particular are widely used in various applications. Some of the recent applications together with pioneering papers where the $J$-matrix has been suggested, can be found in the book [43]. We sketch here the basic relations and ideas of the HORSE formalism for the two-body single-channel scattering following our papers [29, 44–46].

The radial wave function $u_\ell(k, r)$ describing the relative motion in the partial wave with orbital momentum $\ell$ is expanded within the HORSE formalism in an infinite series of radial oscillator functions $R_{N\ell}(r)$,

$$u_\ell(k, r) = \sum_{N=N_0, N_0+2, \ldots, \infty} a_{N\ell}(k) R_{N\ell}(r), \quad (1)$$
Hamiltonian where into an infinite set of linear algebraic equations, elements are respectively.

\[ R_{N\ell}(r) = (-1)^{(N-\ell)/2} \sqrt{\frac{2\Gamma(N/2 - \ell/2 + 1)}{r_0 \Gamma(N/2 + \ell/2 + 3/2)}} \times \left( \frac{r}{r_0} \right)^{\ell+1} \exp \left( -\frac{r^2}{2r_0^2} \right) L_{(N-\ell)/2}^{\ell+1/2} \left( \frac{r^2}{r_0^2} \right). \]  

(2)

Here \( k \) is the relative motion momentum, \( L_n^\ell(z) \) are associated Laguerre polynomials, the oscillator radius \( r_0 = \sqrt{\frac{\hbar}{m_0}} \), \( m_0 \) is the reduced mass of colliding particles, \( \hbar\Omega \) is the oscillator level spacing, \( N = 2n + \ell \) is the oscillator quanta while \( n \) is the oscillator principal quantum number, the minimal value of oscillator quanta \( N_0 = \ell \). Using the expansion (1) we transform the radial Schrödinger equation

\[ H^\ell \psi_{N\ell}(r) = E \psi_{N\ell}(r) \]  

(3)

into an infinite set of linear algebraic equations,

\[ \sum_{N'=N_0,N_0+2,...,\infty} (H_{N'N'}^\ell - \delta_{N'N}) a_{N'\ell}(k) = 0, \quad N = N_0, N_0 + 2, ..., \]  

(4)

where \( H_{N'N'}^\ell = T_{N'N'}^\ell + V_{N'N'}^\ell \) are matrix elements of the Hamiltonian \( H^\ell \) in the oscillator basis, and \( T_{N'N'}^\ell \) and \( V_{N'N'}^\ell \) are kinetic and potential energy matrix elements respectively.

The kinetic energy matrix elements \( T_{N'N'}^\ell \) are known to form a tridiagonal matrix, i.e., the only non-zero matrix elements are

\[ T_{N'N'}^\ell = \frac{1}{2} \hbar \Omega (N + 3/2), \quad T_{N'N' + 2}^\ell = T_{N' + 2N}^\ell = -\frac{1}{4} \hbar \Omega \sqrt{(N - \ell + 2)(N + \ell + 3)}. \]  

(5b)

These matrix elements are seen to increase linearly with \( N \) for large \( N \). On the other hand, the potential energy matrix elements \( V_{N'N'}^\ell \) decrease as \( N, N' \to \infty \). Hence the kinetic energy dominates in the Hamiltonian matrix at large enough \( N \) and/or \( N' \). Therefore a reasonable approximation is to truncate the potential energy matrix at large \( N \) and/or \( N' \), i.e., to approximate the interaction \( V \) by a nonlocal separable potential \( V \) of the rank \( N = (N - N_0)/2 + 1 \) with matrix elements

\[ V_{N'N'}^\ell = \begin{cases} V_{N'N'}^\ell & \text{if } N \leq N_0 \text{ and } N' \leq N_0; \\ 0 & \text{if } N > N_0 \text{ or } N' > N_0. \end{cases} \]  

(6)

The approximation (6) is the only approximation within the HORSE method; for the separable interaction of the type (6), the HORSE formalism suggests exact solutions. Note, the kinetic energy matrix is not truncated within the HORSE theory contrary to conventional variational approaches like the shell model. Hence the HORSE formalism suggests a natural generalization of the shell model.

The complete infinite harmonic oscillator basis space can be divided into two subspaces according to truncation (6): an internal subspace spanned by oscillator functions with \( N \leq N_0 \) where the interaction \( V \) is accounted for and an asymptotic subspace spanned by oscillator functions with \( N > N_0 \) associated with the free motion.

Algebraic equations (4) in the asymptotic subspace take the form of a second order finite-difference equation:

\[ T_{N,N-2}^\ell a_{N-2,\ell}^\text{ass}(E) + (T_{N,N}^\ell - E) a_{N,\ell}^\text{ass}(E) + T_{N,N+2}^\ell a_{N+2,\ell}^\text{ass}(E) = 0. \]  

(7)

Any solution \( a_{N,\ell}^\text{ass}(E) \) of Eq. (7) can be expressed as a superposition of regular \( S_{N\ell}(E) \) and irregular \( C_{N\ell}(E) \) solutions,

\[ a_{N,\ell}^\text{ass}(E) = \cos \delta_\ell S_{N\ell}(E) + \sin \delta_\ell C_{N\ell}(E), \quad N \geq N_0, \]  

(8)

where \( \delta_\ell \) is the scattering phase shift. The solutions \( S_{N\ell}(E) \) and \( C_{N\ell}(E) \) have simple analytical expressions [25, 27, 29, 44, 45]:

\[ S_{N\ell}(E) = \sqrt{\frac{\pi \Gamma(N/2 - \ell/2 + 1)}{\Gamma(N/2 + \ell/2 + 3/2)}} q^{\ell+1} \times \exp \left( -\frac{q^2}{2} \right) L_{(N-\ell)/2}^{\ell+1/2}(q^2), \]  

(9)

\[ C_{N\ell}(E) = (-1)^\ell \sqrt{\frac{\pi \Gamma(N/2 - \ell/2 + 1)}{\Gamma(N/2 + \ell/2 + 3/2)}} \frac{q^{-\ell}}{\Gamma(-\ell + 1/2)} \times \exp \left( -\frac{q^2}{2} \right) \Phi(-N/2 - \ell/2 - 1/2, -\ell + 1/2; q^2), \]  

(10)

where \( \Phi(a; b; z) \) is a confluent hypergeometric function and \( q \) is a dimensionless momentum,

\[ q = \sqrt{\frac{2E}{\hbar \Omega}}. \]  

(11)

The solutions \( a_{N\ell}(E) \) of the algebraic set (4) in the internal subspace \( N \leq N_0 \) are expressed through the solutions \( a_{N\ell}^\text{ass}(E) \) in the asymptotic subspace \( N \geq N_0 \):

\[ a_{N\ell}(E) = G_{N\ell}(E) T_{N,N+2}^\ell a_{N+2,\ell}^\text{ass}(E), \quad N = N_0, N_0 + 2, ..., N. \]  

(12)

Here the matrix elements

\[ G_{N,N'}(E) = -\sum_{\nu=0}^{N-1} \frac{\langle N\ell|\nu\rangle \langle \nu|N'\ell \rangle}{E_\nu - E} \]  

(13)

are related to the Green’s function of the Hamiltonian \( H_N \) which is the Hamiltonian \( H^\ell \) truncated to the internal subspace, and are expressed through eigenenergies \( E_\nu \),
\( \nu = 0, 1, 2, \ldots, N - 1 \) \((N\) is the dimensionality of the basis) and respective eigenvectors \( \langle N\ell|\nu \rangle \) of the Hamiltonian \( H_N \):

\[
\sum_{N'=N_0,N_0+2,\ldots,N} H_{N'} \langle N'\ell|\nu \rangle = E_\nu \langle N\ell|\nu \rangle,
\]

\( N = N_0, N_0 + 2, \ldots, N \). \( \text{(14)} \)

A relation for calculation of the scattering phase shifts \( \delta_\ell \) can be obtained through the matching condition

\[
a_{N\ell}(E) = a_{N\ell}^{\text{ass}}(E). \quad \text{(15)}
\]

Using Eqs. \((8), (12)\) and \((15)\) it is easy to obtain \([25, 27, 29, 44, 45]\)

\[
\tan \delta_\ell(E) = -\frac{S_{N\ell}(E) - \mathcal{G}_{N\ell}(E) T_{N,N+2,\ell}^{\ell} S_{N+2,\ell}(E)}{C_{N\ell}(E) - \mathcal{G}_{N\ell}(E) T_{N,N+2,\ell}^{\ell} C_{N+2,\ell}(E)}.
\]

\( \text{(16)} \)

The respective expression for the \( S\)-matrix reads

\[
S(E) = \frac{C_{N\ell}^{(-)}(E) - \mathcal{G}_{N\ell}(E) T_{N,N+2,\ell}^{\ell} C_{N+2,\ell}^{(-)}(E)}{C_{N\ell}^{(+)}(E) - \mathcal{G}_{N\ell}(E) T_{N,N+2,\ell}^{\ell} C_{N+2,\ell}^{(+)}(E)}, \quad \text{(17)}
\]

where

\[
C_{N\ell}^{(\pm)}(E) = C_{N\ell}(E) \pm S_{N\ell}(E). \quad \text{(18)}
\]

We are using here the single-channel version of the \( \text{HORSE} \) formalism described above. The multi-channel \( \text{HORSE} \) formalism is discussed in detail in Refs. \([25, 29, 44, 45]\).

**B. SS-HORSE method**

A direct \( \text{HORSE} \) extension of modern large-scale shell-model calculations is unpractical. Note, Eq. \((13)\) involves a sum over all shell-model eigenstates of a given spin-parity, i.e., over millions or even billions of states in modern NCSM applications. These states should be accurately separated from those having center-of-mass excitations. Unfortunately one cannot restrict the sum in Eq. \((13)\) to some small enough set of eigenstates: even for the energies \( E \) close enough to one of the low-lying eigenstates \( E_\nu \), the contribution of some high-lying eigenstates to the sum in Eq. \((13)\) can be essential: in model two-body problems describing, e.g., \( n\alpha \) scattering, the growth of the denominator in the r.h.s. of Eq. \((13)\) is compensated by the growth of the numerator; in NCSM calculations of \( ^5\text{He} \), the many-body eigenstates concentrate around the eigenstates of the model two-body Hamiltonian and though the contribution of each particular NCSM eigenstate is small, the sum of their contributions is large and close to the contribution of the respective state of the model Hamiltonian. A calculation of a large number of many-body eigenstates is too computationally expensive. Note, in many-body applications, one also needs to calculate the components \( \langle N\ell|\nu \rangle \) of the wave function which should be projected on the scattering channel of interest; this projection requires numerous applications of Talmi–Moshinsky transformations which increase the computational cost and makes it very difficult to achieve a reasonable accuracy of the final sum in Eq. \((13)\) due to computer noise.

To avoid these difficulties, we propose the SS-HORSE approach which requires calculations of the \( S\)-matrix or phase shifts only at \( E = E_\nu \), i.e., at the energy equal to one of the lowest eigenstates lying above the reaction threshold. Equations \((16)\) and \((17)\) are essentially simplified in this case and reduce to

\[
\tan \delta_\ell(E_\nu) = -\frac{S_{N+2,\ell}(E_\nu)}{C_{N+2,\ell}(E_\nu)}. \quad \text{(19)}
\]

and

\[
S(E_\nu) = \frac{C_{N\ell}^{(-)}(E_\nu)}{C_{N+2,\ell}^{(+)}(E_\nu)}. \quad \text{(20)}
\]

Varying \( N \) and \( \hbar\Omega \) we obtain eigenvalues \( E_\nu \) and hence phase shifts and \( S\)-matrix in some energy interval. An accurate parametrization of \( \delta_\ell(E) \) and \( S\)-matrix in this energy interval makes it possible to extrapolate them to a larger energy interval and to calculate the resonance energy and width.

The use of Eqs. \((19)\) and \((20)\) drastically reduces the computational burden in many-body calculations. Within this SS-HORSE approach we need only one or probably very few low-lying eigenstates which energies should be calculated relative to the respective threshold, e.g., in the case of \( n\alpha \) scattering we need to subtract from the \( ^5\text{He} \) energies the \( ^4\text{He} \) ground state energy. Another interesting and important feature of the SS-HORSE technique is that the Eqs. \((19)\) and \((20)\) do not involve any information regarding the eigenvectors \( \langle N\ell|\nu \rangle \). This essentially simplifies calculations, the information about a particular channel under consideration is present only in the threshold energy used to calculate the eigenenergies \( E_\nu \), and in the channel orbital momentum \( \ell \). Equations \((19)\) and \((20)\) establish some correlations between scattering in different channels when the channel coupling can be neglected, a topic that deserves further investigation but is outside the scope of the present work.

We use here Eqs. \((19)\) and \((20)\) to obtain phase shifts and \( S\)-matrix from Hamiltonian diagonalization results. However these equations can be used in inverse manner: if the phase shifts are known from analysis of experimental scattering data, one can solve Eq. \((19)\) to obtain eigenenergies \( E_\nu \) which the shell model Hamiltonian should have to be consistent with scattering data. The direct use of Eq. \((19)\) essentially simplifies the inverse approach to nucleon-nucleus scattering suggested in Refs. \([14, 15]\).

We see that the scattering phase shifts are determined
by the universal function

\[ f_{NL}(E) = -\arctan \left[ \frac{S_{N+2,\ell}(E)}{C_{N+2,\ell}(E)} \right]. \]  

(21)

This is a smooth monotonically decreasing function which drops down by \( n\pi \) as energy \( E \) varies from 0 to \( \infty \). At low energies when

\[ E \ll \frac{1}{8} \hbar \Omega (N + 2 - \ell)^2, \]  

(22)

one can replace the functions \( S_{N+2,\ell}(E) \) and \( C_{N+2,\ell}(E) \) in Eq. (21) by their asymptotic expressions at large \( N \) (see Refs. [44, 45]) to obtain

\[ f_{NL}(E) \approx f^{lc}_{\ell}(E) = \arctan \left[ \frac{j_\ell(2\sqrt{E/s})}{n_\ell(2\sqrt{E/s})} \right], \]  

(23)

where

\[ s = \frac{\hbar \Omega}{N + 7/2}. \]  

(24)

and \( j_\ell(x) \) and \( n_\ell(x) \) are spherical Bessel and spherical Neumann functions. If additionally

\[ E \gg \frac{1}{4} s = \frac{\hbar \Omega}{4(N + 7/2)}, \]  

(25)

one can use asymptotic expressions for spherical Bessel and Neumann functions in Eq. (23) to get a very simple expression for the function \( f_{NL}(E) \):

\[ f_{NL}(E) \approx -2\sqrt{\frac{E}{s} + \frac{\pi \ell}{2}}. \]  

(26)

The universal function \( f_{NL}(E) \) and its low-energy approximations (23) and (26) are shown in Fig. 1. The basis space in shell model applications in conventionally labeled by the maximal oscillator excitation quanta \( N_{\text{max}} \), and we use \( N_{\text{max}} \) in Fig. 1 to distinguish functions \( f_{NL}(E) \) corresponding to different basis sizes. Obviously,

\[ N = N_{\text{max}} + \ell \]  

(27)

in the two-body scattering problem. The approximation (23) is seen to be very accurate at low energies even for small \( N_{\text{max}} \). This low-energy approximation, as expected, deviates from the function \( f_{NL}(E) \) as the energy \( E \) increases; the energy interval where the approximation (23) accurately describes \( f_{NL}(E) \) increases with \( N \) or \( N_{\text{max}} \) in accordance with inequality (22). In the case \( \ell = 0 \), the simple expression (26) is equivalent to the Eq. (23) and therefore describes the function \( f_{NL}(E) \) with the same accuracy. For \( \ell > 0 \) the simplified approximation (26) deviates from the approximation (23) and the function \( f_{NL}(E) \) at low energies, it can only be used in a relatively small energy interval defined by inequalities (22) and (25).

Due to Eq. (23), equation (19) at low energies can be reduced to

\[ \tan \delta_\ell(E_\nu) = \frac{j_\ell(2\sqrt{E_\nu/s})}{n_\ell(2\sqrt{E_\nu/s})}. \]  

(28)

This equation reveals the scaling at low energies: the oscillator basis parameters \( N \) and \( \hbar \Omega \) are not independent, they are entering equations relating the \( S \)-matrix and phase shifts with the eigenenergies of the Hamiltonian matrix in the oscillator basis not separately but only through the scaling variable \( s \) combining them in a particular manner. The scaling is useful within our approach for selecting eigenenergies \( E_\nu \) obtained with different \( N \) and \( \hbar \Omega \) for the further analysis of phase shifts and \( S \)-matrix poles: the convergence of the results obtained by diagonalization of the Hamiltonian in oscillator basis is achieved within some interval of \( \hbar \Omega \) values starting from some \( N \); the converged results for \( E_\nu \) should describe the same phase shifts with some accuracy; therefore, due to the scaling (28), these converged \( E_\nu \) plotted as functions of the scaling parameter \( s \) lie approximately on the same curve. By plotting \( E_\nu \) vs \( s \) we can pick up for further analysis only those \( E_\nu \) which form some curve as is illustrated later.

The scaling in variational oscillator-basis calculations of bound states was proposed in Refs. [2, 3]. We extend here the scaling property of the oscillator-basis calculations to the continuum states. We prefer to use the scaling parameter \( s \) in energy units rather than the scaling parameter \( \lambda_{sc} \) of Refs. [2, 3, 6] in momentum units or the scaling parameter

\[ L = \sqrt{2(N + 7/2)} r_0 \]  

(29)

in the units of length suggested in Ref. [5]. The parameter \( L \) includes a small correction to the scaling proposed in Refs. [2, 3] which was suggested in Ref. [5] based on numerical results. We obtain this correction automatically in our approach. Having this correction in mind,
we get
\[ s \sim \lambda^2 \sim 1/L^2; \quad (30) \]
in other words, we propose generically the same scaling as discussed in Refs. [2–11, 13] but using another scaling parameter and extending the scaling to continuum states.

We derive the scaling property in a very different approach than that utilized in Refs. [2–5]. Therefore it is interesting to compare these scalings in more detail. One can analytically continue the Eqs. (19) and (20) to the complex energy or complex momentum plane, in particular, one can use these expressions at negative energies corresponding to bound states. Using asymptotic expressions of the functions \( C_{n+2,\ell}(E) \) and \( C_{n-2,\ell}(E) \) at large \( N \) and negative energy \( E \) (see Refs. [44, 45]), we obtain from Eq. (20):
\[
S(E_\nu) = (-1)^\ell \exp \left( -4i \frac{E_\nu}{s} \right), \quad E_\nu < 0. \quad (31)
\]
On the other hand, the \( S \)-matrix \( S(E_\nu) \) at negative energies \( E_\nu \) in the vicinity of the pole associated with the bound state at energy \( E_b < 0 \) can be expressed as [47]
\[
S(E_\nu) = \frac{D_\ell}{i\kappa_\nu - ik_b}, \quad (32)
\]
where \( E_\nu = -\hbar^2 k^2 / 2m \), \( E_b = -\hbar^2 k_b^2 / 2m \), momenta \( \kappa_\nu \) and \( k_b \) are supposed to be positive, and \( D_\ell \) can be expressed through the asymptotic normalization constant \( A_\ell \) [47]:
\[
D_\ell = (-1)^{\ell+1} i |A_\ell|^2. \quad (33)
\]
Combining Eqs. (31)–(33), we obtain:
\[
\kappa_\nu - k_b = -|A_\ell|^2 \exp \left( -4\frac{\kappa_\nu \hbar}{\sqrt{2m} s} \right). \quad (34)
\]
This expression can be used for extrapolating the eigenenergies \( E_\nu \) (or respective momenta \( \kappa_\nu \)) obtained in a finite oscillator basis to the infinite basis space supposing that \( E_\nu \to E_b \) as \( N \to \infty \).

The respective expression for extrapolating the oscillator basis eigenenergies derived in Refs. [2–5] rewritten in our notations, takes the form:
\[
E_\nu - E_b = C_\ell \exp \left( -\frac{4\kappa_\nu \hbar}{\sqrt{2m} s} \right), \quad (35)
\]
There is some similarity, however there is also an essential difference between Eqs. (34) and (35). Both equations have similar exponents in the right-hand-side, however the exponent in our Eq. (34) involves momentum \( \kappa_\nu \) associated with the eigenenergy \( E_\nu \) while Eq. (35) involves momentum \( k_b \) associated with the converged energy \( E_b \) in the limit \( N \to \infty \). In the vicinity of the \( S \)-matrix pole [see Eq. (32)] \( \kappa_\nu \) should not differ much from \( k_b \); we note however that \( k_b \) is conventionally treated as an additional fitting parameter (see Refs. [2–11]), i.e., it is supposed that \( E_b \neq -\hbar^2 k_b^2 / 2m \), and hence there may be an essential difference between \( \kappa_\nu \) and \( k_b \) in applications. Even more important is that the exponent in the right-hand-side controls the difference between the energies \( E_\nu \) and \( E_b \) in Eq. (35) while in our Eq. (34) the exponent controls the difference between the momenta \( \kappa_\nu \sim \sqrt{|E_\nu|} \) and \( k_b \sim \sqrt{|E_b|} \). We plan to examine in detail in a separate publication which of the Eqs. (34) and (35) describes better the results of diagonalizations of realistic Hamiltonians in the oscillator basis for negative eigenenergies \( E_\nu \), and which of them is more accurate in extrapolating the results for bound states obtained in finite oscillator bases to the infinite basis space.

Equations (19) and (20) can be used to obtain the phase shifts and \( S \)-matrix in some range of energies covered by eigenenergies \( E_\nu \) obtained with various \( N \) and \( \hbar \Omega \). To interpolate the energy dependences of the phase shifts and \( S \)-matrix within and to extrapolate them outside this interval, we need accurate formulas for the phase shifts and \( S \)-matrix as functions of energy which we discuss in the next subsection.

### C. Phase shifts and \( S \)-matrix at low energies

The scattering \( S \)-matrix as a function of the complex momentum \( k \) is known [47, 48] to have the following symmetry properties:
\[
S(-k) = \frac{1}{S(k)}, \quad (36a)
\]
\[
S(k^*) = \frac{1}{S^*(k)}, \quad (36b)
\]
\[
S(-k^*) = S^*(k), \quad (36c)
\]
where star is used to denote the complex conjugation. The \( S \)-matrix can have poles either in the lower part of the complex momentum plane or on the imaginary momentum axis [47, 48]. The poles in the lower part of the complex momentum plane at \( k = \kappa_r \pm i\gamma_r \) \((\kappa_r, \gamma_r > 0)\) due to the symmetry relations (36) are accompanied by the poles at \( k = -\kappa_r^* \pm i\gamma_r \) and are associated with resonances at the energy
\[
E_r = \frac{\hbar^2}{2m}(k_r^2 - \gamma_r^2) \quad (37)
\]
and with the width
\[
\Gamma = \frac{2\hbar^2}{m}k_r\gamma_r. \quad (38)
\]
Bound states at energy \( E_b = -\hbar^2 k_b^2 / 2m \) are in correspondence with the poles on the positive imaginary momentum axis at \( k = ik_b \) \((k_b > 0)\), however some positive imaginary momentum poles can appear to be the so-called false or redundant poles [47] which do not represent any bound state. The poles at negative imaginary
momentum at \( k = -i k_v \) \((k_v < 0)\) are associated with virtual states at energy \( E_v = \hbar^2 k_v^2 / 2m \).

If the \( S \)-matrix has a pole close to the origin either in the lower part of the complex momentum plane or on the imaginary momentum axis, it can be expressed at low energies as

\[
S(k) = \Theta(k) S_p(k),
\]

where \( \Theta(k) \) is a smooth function of \( k \) and the pole term \( S_p(k) \) in the case of a bound state or false pole \((p = b)\), virtual \((p = v)\) or a resonant state \((p = r)\) takes the form [48]:

\[
S_b(k) = \frac{k + i k_b}{k - i k_b},
\]

\[
S_v(k) = -\frac{k - i k_v}{k + i k_v},
\]

\[
S_r(k) = \frac{(k + \kappa_r)(k - \kappa^*_r)}{(k - \kappa_r)(k + \kappa^*_r)}.
\]

The \( S \)-matrix is expressed through the phase shifts \( \delta_\ell(k) \) as

\[
S(k) = e^{2i \delta_\ell(k)},
\]

hence the respective phase shifts

\[
\delta_\ell(k) = \phi(k) + \delta_p(k),
\]

where the pole contribution \( \delta_p(k) \) from the bound state takes the form

\[
\delta_b(E) = \pi - \arctan \sqrt{\frac{E}{|E_b|}},
\]

where \( \pi \) appears due to the Levinson theorem [48]. The contributions from the false, virtual and resonant poles are

\[
\delta_f(E) = -\arctan \sqrt{\frac{E}{|E_f|}},
\]

\[
\delta_v(E) = \arctan \sqrt{\frac{E}{E_v}},
\]

\[
\delta_r(E) = -\arctan \frac{a\sqrt{E}}{E - b^2},
\]

where the resonance energy \( E_r \) and width \( \Gamma \) can be expressed through the parameters \( a \) and \( b \) as

\[
E_r = b^2 - a^2/2,
\]

\[
\Gamma = a\sqrt{4b^2 - a^2}.
\]

Due to Eq. (41), the \( S \)-matrix symmetry (36a) require the phase shift \( \delta_\ell(E) \) to be an odd function of \( k \) and its expansion in Taylor series of \( \sqrt{E} \sim k \) includes only odd powers of \( \sqrt{E} \):

\[
\delta_\ell(E) = c \sqrt{E} + d(\sqrt{E})^3 + \ldots
\]

More, since \( \delta_\ell \sim k^{2\ell + 1} \) in the limit \( k \to 0 \), \( c = 0 \) in the case of \( p \)-wave scattering, \( c = d = 0 \) in the case of \( d \)-wave scattering, etc.

In applications to the non-resonant \( n\alpha \) scattering in the \( \frac{1}{2}^+ \) state \((\ell = 0)\), we therefore are using the following parametrization of the phase shifts:

\[
\delta_0(E) = \pi - \arctan \sqrt{\frac{E}{|E_b|}} + c\sqrt{E} + d(\sqrt{E})^3 + f(\sqrt{E})^5.
\]

The bound state pole contribution here is associated with the so-called Pauli-forbidden state. There are resonances in the \( n\alpha \) scattering in the \( \frac{1}{2}^- \) and \( \frac{3}{2}^- \) states \((\ell = 1)\); hence we parametrize these phase shifts as

\[
\delta_1(E) = -\arctan \frac{a\sqrt{E}}{E - b^2} - \frac{a}{b^2} \sqrt{E} + d(\sqrt{E})^3.
\]

This form guarantees that \( \delta_1 \sim k^3 \) in the limit of \( E \to 0 \).

### III. MODEL PROBLEM

To test our SS-HORSE technique, we calculate the phase shifts and resonant parameters of \( n\alpha \) scattering in a two-body approach treating neutron and \( \alpha \) as structureless particles whose interaction is described by the potential WSBG of a Woods–Saxon type with parameters fitted by Bang and Gignoux [49]:

\[
V_{n\alpha} = \frac{V_0}{1 + \exp \left[(r - R_0)/\alpha_0 \right]} + (l \cdot s) \frac{d}{dr} \frac{V_{ls}}{1 + \exp \left[(r - R_1)/\alpha_1 \right]},
\]

where \( V_0 = -43 \text{ MeV} \), \( V_{ls} = -40 \text{ MeV} \cdot \text{fm}^2 \), \( R_0 = 2.0 \text{ fm} \), \( \alpha_0 = 0.70 \text{ fm} \), \( R_1 = 1.5 \text{ fm} \), \( \alpha_1 = 0.35 \text{ fm} \).

We study the \( n\alpha \) phase shifts both in the case of resonant scattering in the \( \frac{3}{2}^- \) partial wave and in the case of non-resonant scattering in the \( \frac{1}{2}^+ \) partial wave. The matrix in the oscillator basis of the relative motion Hamiltonian with the WSBG interaction is diagonalized using \( \hbar \Omega \) values ranging from 2.5 to 50 MeV in steps of 2.5 MeV and \( N_{\text{max}} \) up to 20 for natural parity states \( \frac{3}{2}^- \) and up to 19 for unnatural parity states \( \frac{1}{2}^+ \).

#### A. Partial wave \( \frac{3}{2}^- \)

The lowest eigenstates \( E_0 \) obtained by diagonalization of the model Hamiltonian with the WSBG potential are
are seen to produce smooth single curves. The eigenstates deviating from the common curves in Fig. 2; however the eigenstates obtained with smaller \( N_{\text{max}} \) start deviating from this curve at smaller \( \hbar \Omega \) which correspond to smaller \( s \) values reflecting the convergence patterns of calculations in the finite oscillator basis. This feature is even more pronounced in the plot of the phase shifts obtained directly from eigenstates \( E_0 \) using Eq. (19) (see Fig. 3). We need to exclude from the further SS-HORSE analysis the eigenstates deviating from the common curves in Figs. 2 and 3.

As we already mentioned, the scaling property of our SS-HORSE formalism has much in common with those proposed in Refs. [2, 3]. Using the nomenclature of Refs. [2, 3], we should use only eigenenergies \( E_0 \) which are not influenced by infra-red corrections. According to Refs. [2, 3], these eigenenergies are obtained with \( N_{\text{max}} \) and \( \hbar \Omega \) fitting inequality

\[
\Lambda \equiv \sqrt{m\hbar \Omega (N_{\text{max}} + \ell + 3/2)} > \Lambda_0, \tag{50}
\]

where \( \Lambda_0 \) depends on the interaction between the particles. The value of \( \Lambda_0 = 385 \text{ MeV}/c \) seems to be adequate for the potential WSBG resulting in a reasonable selection of eigenenergies \( E_0 \). The selection of eigenenergies according to this criterion is illustrated by the shaded area in Fig. 4 where we plot eigenenergies \( E_0 \) obtained with various \( N_{\text{max}} \) as functions of \( \hbar \Omega \). These selected eigenstates plotted as a function of the scaling parameter \( s \) in Fig. 5 and the respective SS-HORSE phase shifts in Fig. 6 are seen to produce smooth single curves.

The low-energy resonant \( n\alpha \) scattering phase shifts in the \( \frac{3}{2}^- \) state are described by Eq. (48). We need to fit the parameters \( a, b \) and \( d \) of this equation. Combining Eqs. (19), (27) and (48) we derive the following relation for resonant \( n\alpha \) scattering in the \( \frac{3}{2}^- \) state (\( \ell = 1 \)):

\[
\frac{S_{N_{\text{max}}+3,1}(E_0)}{C_{N_{\text{max}}+3,1}(E_0)} = \tan \left( -\arctan \frac{a\sqrt{E_0}}{E_0 - b^2} - \frac{a}{b^2} \sqrt{E_0} + d (\sqrt{E_0})^3 \right). \tag{51}
\]

We assign some values to the parameters \( a, b \) and \( d \) and solve this equation to find a set of \( E_0 \) values, \( C^{(i)}_0 = E_0(N_{\text{max}}^i, \hbar \Omega^i), i = 1, 2, \ldots, D \), for each combination of \( N_{\text{max}} \) and \( \hbar \Omega \) [note, \( \hbar \Omega \) enters definitions of functions \( S_{N,\ell}(E) \) and \( C_{N,\ell}(E) \), see Eqs. (9)–(11)]. The resulting set of \( C^{(i)}_0 \) is compared with the set of selected

![FIG. 2. The lowest \( \frac{3}{2}^- \) eigenstates \( E_0 \) of the model Hamiltonian with WSBG potential obtained with various \( N_{\text{max}} \) and \( \hbar \Omega \) plotted as a function of the scaling parameter \( s \).](image)

![FIG. 4. The lowest \( \frac{3}{2}^- \) eigenenergies \( E_0 \) of the model WSBG Hamiltonian obtained with various \( N_{\text{max}} \) (symbols) as functions of \( \hbar \Omega \) and their selection for the SS-HORSE analysis according to inequality \( \Lambda > 385 \text{ MeV}/c \). The shaded area shows the selected \( E_0 \) values. Solid lines are solutions of Eq. (51) for energies \( E_0 \) with parameters \( a, b \) and \( d \) obtained by the fit.](image)
TABLE I. $\frac{3}{2}^-$ resonance in $n\alpha$ scattering with model WSBG potential: fitting parameters $a$, $b$, $d$ of Eq. (51), resonance energy $E_r$ and width $\Gamma$, rms deviation of fitted energies $\Xi$ and the number of these fitted energies $D$ for different selections of eigenvalues in comparison with exact results for $E_r$ and $\Gamma$ obtained by numerical location of the $S$-matrix pole. For the $N_{\text{max}} \leq 6$ selection, $\Xi$ and $D$ for all energies from the previous selection are shown within brackets.

| Selection                  | $a$ $\text{(MeV)}$ | $b^2$ $\text{(MeV)}$ | $d \cdot 10^3$ $\text{(MeV}^{-\frac{3}{2}})$ | $E_r$ $\text{(MeV)}$ | $\Gamma$ $\text{(MeV)}$ | $\Xi$ $\text{(keV)}$ | $D$ |
|----------------------------|---------------------|-----------------------|-----------------------------------------------|---------------------|------------------|-----------------|-----|
| $\Lambda > 385 \text{MeV}/c$ | 0.412               | 0.948                 | 5.41                                          | 0.863               | 0.785            | 37              | 156 |
| $N_{\text{max}} \leq 6$         | 0.411               | 0.948                 | 5.30                                          | 0.863               | 0.782            | 70(38)          | 38(156) |
| Exact                      |                     |                       |                                               |                     |                  |                 |     |

The behavior of $E_0$ as functions of $\hbar \Omega$ dictated by Eq. (51) with the fitted optimal parameters for various $N_{\text{max}}$ values is depicted by solid curves in Figs. 4 and 5. It is seen that these curves accurately describe the selected eigenvalues $E_0$ obtained by the Hamiltonian diagonalization. Note however a small deviation of the curve in Fig. 5 from the diagonalization results at large energies obtained with $N_{\text{max}} = 2$ where the scaling becomes inaccurate, see Eq. (22). The phase shifts $\delta_1(E)$ obtained by Eq. (48) with fitted parameters are shown in the Fig. 6. It is seen that the SS-HORSE phase shifts are in excellent correspondence with the exact results obtained by numerical integration of the Schrödinger equation.

In the above analysis we used oscillator bases with $N_{\text{max}}$ values up to $N_{\text{max}} = 20$. Such large $N_{\text{max}}$ are accessible in two-body problems but are out of reach in modern many-body shell model applications. Therefore it is very important to check whether a reasonable

![Fig. 5](image-url)

(51) for energies $E_0$ with parameters $a$, $b$ and $d$ obtained by the fit with the respective selection of eigenstates.

![Fig. 6](image-url)  
**FIG. 6.** The $\frac{3}{2}^-$ WSBG phase shifts obtained using Eq. (19) directly from eigenstates $E_0$ selected according to $\Lambda > 385 \text{MeV}/c$ (symbols). The solid curve depicts the phase shifts of Eq. (48) with parameters $a$, $b$ and $d$ obtained by the fit with the respective selection of eigenstates; the dashed curve is obtained by a numerical integration of the Schrödinger equation.
the accuracy of SS-HORSE phase shift and resonance parameter calculations can be achieved with significantly smaller $N_{\text{max}}$.

We remove from the set of selected $3^-_V$ eigenstates $E_0^{(i)}$ those obtained with $N_{\text{max}} > 6$ and use this new selection illustrated by Figs. 7 and 8 to calculate phase shifts and resonant parameters. All eigenenergies from this selection lie outside the resonance region as is seen in Fig. 9 where we plot the phase shifts as a function of energy. The SS-HORSE fit (see Table I) nevertheless accurately reproduces the exact phase shifts (see Fig. 9) even in the resonance region and the $3^-_V$ resonance energy $E_r$ and width $\Gamma$ (see Table I). To get such accuracy, it is very important to use the adequate phase shift parametrization (48) which guarantees the low-energy phase shift behaviour $\delta_\ell \sim k^{2\ell+1}$ and an accurate description of the resonance region by the pole term (43d): our previous study [37] has clearly demonstrated that it is impossible to reproduce the resonant parameters and phase shifts in a wide enough energy interval without paying special attention to the low-energy phase shift description and by using the less accurate Breit–Wigner resonant phase shifts instead of the pole term (43d) even when large $N_{\text{max}}$ eigenstates $E_0$ are utilized to say nothing about the selection of eigenstates obtained with small $N_{\text{max}}$.

Solid lines in Figs. 4 and 7 present the eigenenergies $E_0$ for various $N_{\text{max}}$ values as functions of $h\Omega$ obtained from the respective phase shift parametrization. It is seen that we accurately describe not only the eigenenergies from the shaded area utilized in the fit but also those corresponding to a wider range of $h\Omega$ values. It is even more interesting that in the case of Fig. 7 where fitted are only the states with $N_{\text{max}} \leq 6$, we also reproduce the eigenenergies obtained with much larger $N_{\text{max}}$ values with nearly the same rms deviation as in the case of the previous selection (see Table I) when those larger $N_{\text{max}}$ eigenenergies were included in the fit. In other words, our SS-HORSE fit to the diagonalization results in small basis spaces makes it possible to ‘predict’ the diagonalization results obtained with much larger oscillator bases.

The predictive ability of the SS-HORSE approach clearly demonstrates the reliability of the potential truncation (6). Note, the absolute values of discarded potential energy matrix elements $\tilde{V}_{NN'}^\ell$ with $N > N'$ or $N' > N$ are not small in case of small enough $N_{\text{max}}$ values; however the contributions of these discarded matrix elements are known to approximately cancel each other and their net contribution appears to be small compared to the kinetic energy matrix elements $T_{NN'}^\ell$ and $T_{NN',N\pm2}^\ell$ for $N > N$. As a result, in larger oscillator bases with the complete account of the potential energy we obtain nearly the same results as in the case when the Hamiltonian matrix is extended to the same basis size by the
kinetic energy matrix elements only. This feature is confirmed below in our 5-body NCSM-SS-HORSE applications; it is very promising for shell-model applications to heavier nuclear systems and suggests a very efficient method of extrapolating the shell-model results to larger basis spaces.

B. Partial wave $\frac{1}{2}^+$

There are no resonances in the $n\alpha$ scattering in the $\frac{1}{2}^+$ partial wave. However, as it has been indicated in Refs. [14, 15], the nuclear shell model should generate eigenstates in non-resonant energy intervals in continuum to be consistent with scattering observables. Therefore it is interesting to test with the WSBG potential the ability of the SS-HORSE approach to describe the $\frac{1}{2}^+$ non-resonant $n\alpha$ scattering.

The low-energy $n\alpha$ scattering phase shifts in the $\frac{3}{2}^+$ state are described by Eq. (47). We shall see that to get the same quality fit as in the case of the odd-parity resonant scattering, we need in this case terms up to the $5^{th}$ power of $\sqrt{E}$ in the Taylor expansion of the background phase; therefore we preserve in Eq. (48) more terms than in Eq. (47) for an additional fitting parameter as a preparation to many-body NCSM calculations where it is impossible to obtain the energy of the Pauli-forbidden state. However, we treat $E_0$ as an additional fitting parameter to obtain a bound state at energy $E_0$ which mimics the Pauli-forbidden state in the $n\alpha$ scattering. For this reason we use Eq. (48) to adjust $E_0$ instead of $E_1$ as in the case of odd parity partial waves, the deviations from the common curve are much more pronounced in the case of odd parity partial waves, the deviations from the common curve are much more pronounced in the plot of the SS-HORSE phase shifts corresponding to these eigenstates (see Fig. 12) which clearly indicates the need to select eigenstates for the SS-HORSE fitting.

As in the case of the odd parity $\frac{3}{2}^+$ state, we use the $\Lambda > 385 \text{ MeV}/c$ selection of eigenenergies as is illustrated by Fig. 13 and by the shaded area in Fig. 10. The obtained fitting parameters of Eq. (54) are presented in Table II. It is interesting that the fitted energy $E_0$ differs essentially from the exact value which is the energy of the bound state in the WSBG potential. The SS-HORSE $\frac{1}{2}^+$ phase shifts nevertheless are seen in Fig. 13 to be nearly

\begin{equation}
\begin{aligned}
- S_{N_{\text{max}}+3.0}(E_\nu) &= \tan\left( \pi - \arctan \frac{E_\nu}{|E_b|} \right) \\
&+ c\sqrt{E_\nu} + d\left( \sqrt{E_\nu}^3 + f\left( \sqrt{E_\nu}^5 \right) \right),
\end{aligned}
\end{equation}

where $\nu = 1$. We assign some values to the fitting parameters $E_0$, $c$, $d$ and $f$ and solve Eq. (54) to find a set of $E_1$ values, $E_1^{(i)} = E_1(N_{\text{max}}^i, h\Omega)$, $i = 1, 2, \ldots, D$, for each combination of $N_{\text{max}}$ and $h\Omega$ and minimize the rms deviation from the selected eigenvalues $E_1^{(i)}$ obtained by the Hamiltonian diagonalization, see Eq. (52) where the subindex $0$ should be replaced by $1$, to find the optimal values of the fitting parameters.

The lowest continuum $\frac{3}{2}^+$ eigenstates $E_1$ of the model WSBG Hamiltonian are shown as functions of $h\Omega$ for various $N_{\text{max}}$ in Fig. 10 and as a function of the scaling parameter $s$ in Fig. 11. All eigenenergies in this case seem to lie approximately on the same curve in Fig. 11; however, as in the case of odd parity partial waves, the deviations from the common curve are much more pronounced in the plot of the SS-HORSE phase shifts corresponding to these eigenstates (see Fig. 12) which clearly indicates the need to select eigenstates for the SS-HORSE fitting. The lowest continuum $\frac{3}{2}^+$ states in $^5\text{He}$ are unnatural parity states, hence $N_{\text{max}}$ takes odd values within NCSM, the minimal oscillator quanta $N_0 = 1$ in the five-body $n\alpha$ system, and

\begin{equation}
N = N_{\text{max}} + N_0
\end{equation}

is even. To retain a correspondence with NCSM, we are using $N_{\text{max}}$ to define the oscillator basis also in our model two-body problem. We note that in this case the $N_{\text{max}}$ is formally related to $N$ according to Eq. (27) where $\ell = 0$, and $N_{\text{max}}$ should be even for even $N$. To have a closer correspondence with NCSM, we use Eq. (53) with $N_0 = 1$ within our model two-body problem instead of Eq. (27) to relate $N_{\text{max}}$ to $N$, i.e., due to our NCSM-like definition, the $\frac{1}{2}^+$ eigenstates are labelled below by odd $N_{\text{max}}$ values. Note, the definitions (27) and (53) result in the same $N_{\text{max}}$ in the case of odd-parity $\frac{3}{2}^-$ and $\frac{1}{2}^+$ $n\alpha$ partial waves.

Combining Eqs. (19), (47) and (53), we derive for the $n\alpha$ scattering in the $\frac{1}{2}^+$ partial wave:

\[ - S_{N_{\text{max}}+3.0}(E_\nu) = \tan\left( \pi - \arctan \frac{E_\nu}{|E_b|} \right) + c\sqrt{E_\nu} + d\left( \sqrt{E_\nu}^3 + f\left( \sqrt{E_\nu}^5 \right) \right), \]
TABLE II. $\frac{1}{2}^+$ $n\alpha$ scattering with model WSBG potential: fitting parameters $E_b$, $c$, $d$ and $f$ of Eq. (54), rms deviation of fitted energies $\Xi$ and the number of these fitted energies $D$ for different selections of eigenvalues. For the $N_{\text{max}} \leq 5$ selection, $\Xi$ and $D$ for all energies from the previous selection are shown within brackets.

| Selection          | $E_b$ (MeV) | $c$ (MeV$^{-\frac{1}{2}}$) | $d \cdot 10^3$ (MeV$^{-\frac{1}{2}}$) | $f \cdot 10^5$ (MeV$^{-\frac{3}{2}}$) | $\Xi$ (keV) | $D$ |
|--------------------|-------------|----------------------------|--------------------------------------|--------------------------------------|-------------|-----|
| $\Lambda > 385$ MeV/c | $-6.841$    | $-0.157$                  | $+1.19$                              | $-0.888$                             | $163$       | $151$ |
| $N_{\text{max}} \leq 5$ | $-6.853$    | $-0.156$                  | $+1.19$                              | $-0.888$                             | $332(163)$  | $35(151)$ |
| Exact              | $-9.85$     |                           |                                      |                                      |             |     |

FIG. 11. The lowest continuum $\frac{1}{2}^+$ WSBG eigenstates $E_1$ as a function of the scaling parameter $s$. The solid curve depicts solutions of Eq. (54) for energies $E_1$ with parameters $E_b$, $c$, $d$ and $f$ obtained by the fit with the $\Lambda > 385$ MeV/c selection of eigenstates.

indistinguishable from the exact ones up to the energies of about 70 MeV where the SS-HORSE phase shifts governed by $N_{\text{max}} = 1$ eigenstates slightly differ from exact.

FIG. 12. The $\frac{1}{2}^+$ phase shifts obtained directly from the WSBG eigenstates $E_1$ using Eq. (19).

We note that the WSBG bound state has a large binding energy, the respective $S$-matrix pole is far enough from the real momentum axis and hence has a minor influence on the phase shifts. This result indicates that one should not take seriously the energies of bound states obtained by the fit to the scattering data only, at least for well-bound states. We note however that the energy of this Pauli-forbidden state can be accurately calculated within the SS-HORSE approach by including the lowest WSBG negative energy eigenstate $E_0$ in the fit. Nevertheless, such a fit is of no interest for many-body NCSM applications which do not generate Pauli-forbidden states.

To examine a possibility of describing the low-energy $\frac{1}{2}^+$ phase shifts using only the diagonalization results in small basis spaces, we remove from the previous selection the eigenenergies $E_1$ obtained with $N_{\text{max}} > 5$ as is illustrated by Figs. 14 and 15. We obtain nearly the same values of the fitting parameters as is seen from Table II. The largest though still small enough difference is obtained for the fitted $E_b$ values which, as has been already noted, does not play an essential role in the phase shifts. Therefore it is not surprising that we get an excellent de-
They have demonstrated that the eigenenergies \( E_{\nu} \) as functions of the scaling parameter \( \lambda_{sc} \sim \sqrt{s} \) tend to a constant as \( \lambda_{sc} \) approaches 0; this constant is the convergence limit of the respective eigenenergies in the infinite basis. Our study extends the scaling patterns of the harmonic oscillator eigenstates to the case of states in the continuum. In this case the eigenenergies should approach 0 as the basis is expanded infinitely. The solid line in Fig. 11 demonstrates the behaviour of eigenenergies in the continuum \( E_{1} \) as a function of the scaling parameter \( s \) in the case of a system which has a bound state and does not have resonances in the low-energy region; the respective low-energy phase shifts are described by Eq. (47), a general formula for this case. The eigenstates are seen to be a smooth monotonic function of \( s \) (or \( \lambda_{sc} \)) which tends, as expected, to zero as \( s \to 0 \).

It is seen in Fig. 11 that in the high-energy region the WSBG eigenstates deviate from the solid curve presenting the solutions of Eq. (54) for the respective \( N_{\text{max}} \) and \( h\Omega \) values. Note, these eigenstates correspond to small \( N_{\text{max}} \) values for which the scaling condition (22) at large energies is not fulfilled and hence the scaling properties (23) and (28) become inaccurate. As a result, the solutions of Eq. (54) plotted as a function of the scaling parameter \( s \) deviate from the WSBG eigenstates while the same WSBG eigenstates are perfectly described by the Eq. (54) solutions when plotted as functions of \( h\Omega \) for each \( N_{\text{max}} \) in Fig. 10. The inaccuracy of the scaling is much less pronounced in Fig. 5 where the energies are much smaller.

The solid lines in Figs. 5 and 8 demonstrate the behaviour of the eigenstates \( E_{0} \) as a function of the scaling parameter \( s \) when the low-energy phase shifts are given by Eq. (48) which is a general formula describing a system which does not have a bound state but has a low-energy resonance. We see again a smooth monotonically increasing function of \( s \) with a large enough derivative at large \( s \). At smaller \( s \) when the energy approaches the resonant region, the derivative of \( E_{0}(s) \) decreases; this decrease of the derivative is more pronounced for narrow resonances. Figure 16 where the function \( E_{0}(s) \) from Fig. 5 is shown in a larger scale together with the resonant region, demonstrates that the further decrease of \( s \) strongly enhances the derivative of this function at the energies below the resonance energy \( E_{r} \). When the function \( E_{0}(s) \) leaves the resonant region at smaller \( s \) values, the next eigenstate \( E_{1}(s) \) (not shown in the figure) approaches the resonant region from above.

These are the general convergence trends of the positive energy eigenstates obtained in the oscillator basis.

Concluding this section, we have demonstrated using the WSBG potential as an example that the proposed SS-HORSE technique is adequate for the description of low-energy scattering phase shifts and resonance energies \( E_{r} \) and widths \( \Gamma \). A very encouraging sign for many-body shell-model applications is that the resonance parameters and phase shifts can be obtained nearly without losing the accuracy by using within the
We discuss here the application of our SS-HORSE technique to \(n\alpha\) scattering phase shifts and resonance parameters based on \(ab\ initio\) many-body calculations of \(^5\)He within the NCSM with the realistic JISP16 \(NN\) interaction. The NCSM calculations are performed using the code MFDn [50, 51] with \(2 \leq N_{\text{max}} \leq 18\) for both parities and with \(\hbar\Omega\) values ranging from 10 to 40 MeV in steps of 2.5 MeV.

As it has been already noted above, for the SS-HORSE analysis we need the \(^5\)He energies relative to the \(n + \alpha\) threshold. Therefore from each of the \(^5\)He NCSM odd (even) parity eigenenergies we subtract the \(^4\)He ground state energy obtained by the NCSM with the same \(\hbar\Omega\) and the same \(N_{\text{max}}\) (with \(N_{\text{max}} - 1\)) excitation quanta, and in what follows these subtracted energies are called NCSM eigenenergies \(E_{\nu}\). Only these \(^5\)He NCSM eigenenergies relative to the \(n + \alpha\) threshold are discussed below.

We note here that the NCSM utilizes the truncation based on the many-body oscillator quanta \(N_{\text{max}}\) while the SS-HORSE requires the oscillator quanta truncation of the interaction describing the relative motion of neutron and \(\alpha\) particle. A justification of using \(N_{\text{max}}\) for the SS-HORSE analysis is obvious if the \(\alpha\) particle is described by the simplest four-nucleon oscillator function with excitation quanta \(N^{\alpha}_{\text{max}} = 0\). Physically it is clear that the use of \(N_{\text{max}}\) within the SS-HORSE should work well also in a more general case when the \(\alpha\) particle is presented by the wave function with \(N^{\alpha}_{\text{max}} > 0\) due to the dominant role of the zero-quanta component in the \(\alpha\) particle wave function. Instead of trying to rigorously justify the use of \(N_{\text{max}}\) within the SS-HORSE by lengthy algebraic manipulations, we suggest an \(a\ posteriori\) justification: we demonstrate below that we obtain \(n\alpha\) phase shift parametrizations consistent with the NCSM results obtained with very different \(N_{\text{max}}\) and \(\hbar\Omega\) values; moreover, we are able to ‘predict’ the NCSM results with large \(N_{\text{max}}\) using the phase shift parametrizations based on the NCSM calculations with much smaller model spaces. It will be clearly impossible if the use of \(N_{\text{max}}\) truncation for the SS-HORSE analysis will not work properly.

**IV. SS-HORSE NCSM CALCULATION OF RESONANCES IN \(n\alpha\) SCATTERING**

We utilize the same Eq. (51) to fit the parameters describing the low-energy \(\frac{1}{2}^-\) and \(\frac{3}{2}^-\) phase shifts as in the model problem; the only difference is that the lowest energy eigenstates \(E_0\) are obtained now from the many-body NCSM calculations. These lowest \(\frac{1}{2}^-\) NCSM eigenstates are shown in Fig. 17 as functions of \(\hbar\Omega\) for various \(N_{\text{max}}\) values. Figure 18 presents these eigenstates \(E_0\) as a function of the scaling parameter \(s\) while Fig. 19 presents the \(\frac{3}{2}^-\) phase shifts obtained directly from them using Eq. (19). Figures 18 and 19 clearly demonstrate the need of the eigenstate selection since many points in these figures deviate strongly from the common curves formed by other points. On the other hand, these figures demonstrate the convergence achieved in large \(N_{\text{max}}\) calculations: the deviation from the common curves occurs
at smaller \( \hbar \Omega \) values as \( N_{\text{max}} \) increases and all results from the largest available NCSM basis spaces seem to lie on the single common curves with the exception of only very few eigenenergies obtained with \( \hbar \Omega < 15 \text{ MeV} \).

Our first selection is the eigenstates fitting inequality \( \Lambda > 600 \text{ MeV}/c \), the value recommended in Refs. [2, 3] for the JISP16 NN interaction. This selection is illustrated by the shaded area in Fig. 17; common curves are formed by the selected eigenenergies \( E_0 \) plotted as a function of the scaling parameter \( s \) in Fig. 20 and by the phase shifts obtained directly from these eigenenergies with the help of Eq. (48) in Fig. 21. We get an accurate fit of the selected NCSM eigenenergies with the rms deviation of 31 keV, the obtained values of the fitting parameters \( a, b, d \) of Eq. (51) and the \( \frac{3}{2}^- \) resonance energy \( E_r \) and width \( \Gamma \) are presented in Table III. The fit accuracy is also illustrated by solid lines in Figs. 17, 20 and 21 obtained using our fitting parameters: these curves are seen to reproduce the selected NCSM energies \( E_0 \) in Figs. 17 and 20 and the corresponding phase shifts in Fig. 21.

The JISP16 NN interaction generates the \( \frac{3}{2}^- \) phase shifts reproducing qualitatively but not quantitively the results of phase shift analysis of Refs. [52] of \( n\alpha \) scattering data as is seen in Fig. 21. We obtain the resonance energy \( E_r \) slightly above the experimental value, the difference is about 0.2 MeV (see Table III). The resonance width \( \Gamma \) is also overestimated by JISP16, the difference between the JISP16 prediction and experiment is about 0.4 MeV. We present in Fig. 21 and in the last row of Table III.
TABLE III. $\frac{3}{2}^-$ resonance in $\alpha \alpha$ scattering from the $^5$He NCSM calculations with JISP16 NN interaction: fitting parameters $a$, $b$, $d$ of Eq. (51), resonance energy $E_r$ and width $\Gamma$, rms deviation of fitted energies $\Xi$ and the number of these fitted energies $D$ for different selections of eigenvalues in comparison with the analysis of experimental data in various approaches of Refs. [53] and [14] and with the fit by Eq. (48) of the phase shifts $\delta_1$ extracted from experimental data in Ref. [52]. For the $N_{\text{max}} \leq 4$ selection, $\Xi$ and $D$ for all energies from the manual selection are shown within brackets.

| Selection | $a$ (MeV$^2$) | $b^2$ (MeV) | $d \cdot 10^4$ (MeV$^{-\frac{3}{2}}$) | $E_r$ (MeV) | $\Gamma$ (MeV) | $\Xi$ (keV) | $D$ |

| $N_{\text{max}} \leq 4$ | 0.515 | 1.025 | +101 | 0.892 | 1.008 | 106(81) | 11(68) |

Nature:
- $R$-matrix [53] $\Xi$ | 0.80 | 0.65 |
- $J$-matrix [14] $\Xi$ | 0.772 | 0.644 |
- Fit $\delta_1$ of Ref. [52] $\Xi$ | 0.358 | 0.839 | +55.9 | 0.774 | 0.643 | 0.21$^\circ$ | 26 |

We would like to use within the SS-HORSE approach the eigenstates obtained with sufficiently large $N_{\text{max}}$ and with very small $h\Omega$; the same conclusion follows from our $ab$ initio many-body study of the system of four neutrons (tetraneutron) in the continuum [54]. According to the $\Lambda > \Lambda_0$ rule we either exclude these large $N_{\text{max}}$—small $h\Omega$ eigenstates or include in the fit some small $N_{\text{max}}$ states which strongly deviate from common curves on the plots of $E_r$ vs $s$ or $\delta_1$ vs $E$.

The ultraviolet cutoff $\Lambda_0$ was introduced in Refs. [2, 3] with an idea that the oscillator basis should be able to describe in the many-body system the short-range (high-momentum) behaviour of the two-nucleon interaction employed in the calculations; thus the $h\Omega$ cannot be too small since oscillator functions with small $h\Omega$ have a large radius (corresponding to small momentum) and are not able to catch the short-range (high-momentum) peculiarities of a particular $NN$ potential. We imagine this concept to be insufficient at least in some cases. In light nuclei where binding energies are not large, the structure of the wave function can be insensitive to the short-range $NN$ potential behaviour associated with high relative momentum. Much more important is the radius of the state under consideration, e.g., we can expect an adequate description of the ground state only if the highest oscillator function in the basis has at least one node within the radius of this state, two nodes are required within the radius of the first excited state, etc. Therefore the minimal acceptable $h\Omega$ value depends strongly on the state under consideration and may be insensitive to the inter-nucleon interaction. This is particularly important for loosely-bound nuclear states or for low-energy scattering states. In the case of scattering, the wave function at low energies can have a very distant first node and not only permits but just requires the use of oscillator functions with very small $h\Omega$ values and large radius.

We cannot formulate a simple rule or formula for selecting eigenstates acceptable for the SS-HORSE analysis, instead we pick up manually individual states with eigenenergies $E_0$ lying to the right from the minimum of the $h\Omega$ dependence for each $N_{\text{max}}$ in Fig. 17 and lying on or close to the common curve in Figs. 18 and 19. These manually selected eigenstates and the respective phase shifts are presented in Figs. 22, 23 and 24. The results
of the fit with this selection of eigenstates are presented in the second line of Table III. We obtain an accurate fit with the rms deviation of eigenenergies of 70 keV; this number however depends on the selection criteria like the acceptable distance from the common curve formed by other points in Figs. 23 and 24. Comparing Figs. 17 and 22 we see that our manual selection makes it possible to describe eigenenergies with small \( N_{\text{max}} \) which were far from theoretical curves in Fig. 17. These small \( N_{\text{max}} \) states have large energies, and their inclusion in the SS-HORSE analysis extends the description of the phase shifts in the high-energy region in Fig. 24 pushing them closer to the phase shift analysis of the experimental \( n\alpha \) scattering data in this region as compared with Fig. 21. These changes in the phase shift behavior at larger energies correspond to a drastic change of the fitting parameter \( d \) which is the coefficient of the highest power term in the expansion (48). At smaller energies including the resonance region, the phase shifts obtained from the fits with the manual and with the \( \Lambda > 600 \text{ MeV}/c \) selections are nearly the same, and we get close values of the respective fitting parameters \( a \) and \( b \) and hence small changes of the resonance energy \( E_r \) and width \( \Gamma \) due to the switch from one selection to the other.

It is very interesting to investigate whether we can get reasonable phase shifts and resonance parameters using only the NCSM eigenstates from small basis spaces. From our manually selected eigenstates we select only those obtained with \( N_{\text{max}} = 2 \) and 4. This selection and the results obtained by the fit are depicted in Figs. 25, 26 and 27. All eigenenergies \( E_0 \) involved in this fit are significantly above the resonant region (see Fig. 27). Nev-
The lowest $^5\text{He}$ eigenstates of $\frac{3}{2}^-$ and $\frac{1}{2}^-$ partial waves are presented in Figs. 29 and 30 as functions of the scaling parameter $s$. The eigenenergies tend to form single common curves demonstrating the convergence of many-body NCSM calculations. However, we see that many eigenstates diverge from the common curves and lie far from them, thereby demonstrating the need to select the states for the SS-HORSE analysis.

B. Partial wave $\frac{1}{2}^-$

The lowest $\frac{1}{2}^-$ eigenstates of $^5\text{He}$ from the NCSM calculations with JISP16 $NN$ interaction are presented in Fig. 28 as functions of $\hbar \Omega$ and in Fig. 29 as a function of the scaling parameter $s$. Fig. 30 presents the respective $n\alpha$ phase shifts. The eigenenergies in Figs. 29 and 30 tend to form single common curves demonstrating the convergence of many-body NCSM calculations, however, we see that many eigenstates diverge from the common curves and lie far from them, thereby demonstrating the need to select the states for the SS-HORSE analysis.

As in the case of the $\frac{3}{2}^-$ partial wave, we start from the $\Lambda > 600 \text{ MeV}/c$ eigenstate selection recommended for the JISP16 $NN$ interaction in Refs. [2, 3] which is illustrated in Figs. 28 and 31, the respective phase shifts...

are shown in Fig. 32. The selected states form reasonably smooth common curves in Figs. 31 and 32 making possible an accurate fit of parameters in Eq. (48); the obtained fitted parameters can be found in Table IV. We get a good description of the $\frac{1}{2}^-$ resonance energy and width however the phase shift behaviour extracted from the experimental $n\alpha$ scattering data is reproduced qualitatively but not quantitatively (see Fig. 32). Note however that the fit parameters derived from the experimental data and JISP16 results (Table IV) are close with the exception of the parameter \(d\) which contribution is very small at energies below 20 MeV. Figure 28 shows that we reproduce not only the eigenstate energies from the shaded area that were fitted but also many other eigenstates not included in the fit, especially small-$N_{\text{max}}$ eigenstates, thus suggesting to perform a manual eigenstate selection which will involve many more eigenergies in the SS-HORSE analysis.

Our manual selection of the lowest $\frac{1}{2}^-$ eigenstates in

**FIG. 32.** The $\frac{1}{2}^-$ $\alpha$ phase shifts generated by the $\Lambda > 600$ MeV/c selected $^5\text{He}$ eigenstates \(E_0\). See Fig. 21 for details.
\(^{5}\text{He}\) is shown in Figs. 33 and 34 while the respective \(n\alpha\) phase shifts are presented in Fig. 35, the results of the fit are given in Table IV. As in the case of the \(\frac{1}{2}^-\) \(n\alpha\) partial wave, the inclusion of the additional eigenstates in the fit does not affect the phase shifts at smaller energies including the resonance region. However, including the additional eigenstates pushes the phase shifts up in the direction of the phase shift analysis at larger energies.

The \(\frac{1}{2}^-\) resonance energy and width and the parameters of the phase shift fit by Eq. (48) are seen from Table IV to change only slightly with the exception of the parameter \(d\) responsible for the phase shift behaviour at higher energies.

It is very interesting and important to examine whether it is possible to get a reasonable description of the resonance and phase shifts in the \(\frac{1}{2}^-\) \(n\alpha\) scattering using only eigenstates obtained in many-body NCSM calculations in small bases. In the case of the \(\frac{1}{2}^-\) \(n\alpha\) scattering we manage to derive very good phase shifts from the \(N_{\text{max}} \leq 4\) NCSM eigenstates. Therefore we try the \(N_{\text{max}} \leq 4\) eigenstate selection also in the \(\frac{1}{2}^-\) partial wave, see Figs. 36, 37 and 38. This selection clearly fails to reproduce the phase shifts and resonance parameters which differ essentially from the converged results obtained with the manual selection of the \(\frac{1}{2}^-\) \(^{5}\text{He}\) eigenstates (see Fig. 21 and Table IV); we see also in Fig. 36 that the fit to the \(N_{\text{max}} \leq 4\) eigenstates from the shaded area fails to ‘predict’ the eigenenergies \(E_0\) obtained with larger \(N_{\text{max}}\) values. That is not surprising because the plots of the \(N_{\text{max}} \leq 4\) eigenenergies as a function of the scaling parameter \(s\) (Fig. 37) and of the respective phase shifts as a function of energy (Fig. 38) do not form

smooth common curves.

However an entirely different result is obtained by selecting for the SS-HORSE analysis the $^5\text{He} \frac{1}{2}^-$ NCSM results from basis spaces with $4 \leq N_{\text{max}} \leq 6$. For the $4 \leq N_{\text{max}} \leq 6$ selection we pick up 10 eigenstates with the smallest $N_{\text{max}}$ values out of 60 manually selected before $\frac{1}{2}^-$ eigenstates. This eigenstate selection and the respective results are illustrated by Figs. 39, 40 and 41. The selected eigenenergies are seen to form sufficiently smooth curves in Figs. 40 and 41. The parameter fit results in nearly the same phase shifts (Fig. 41) as in the case of the manual eigenstate selection, we get also very close values of the resonance energy and width and fitting parameters listed in Table IV. Figure 39 demonstrates

FIG. 37. Selected lowest $^5\text{He} \frac{1}{2}^-$ eigenstates $E_0$ obtained in NCSM with $N_{\text{max}} \leq 4$ as a function of the scaling parameter $s$. See Fig. 5 for other details.

FIG. 40. Selected lowest $^5\text{He} \frac{1}{2}^-$ eigenstates $E_0$ obtained in NCSM with $4 \leq N_{\text{max}} \leq 6$ as a function of the scaling parameter $s$. See Fig. 5 for other details.

FIG. 41. The $\frac{1}{2}^-$ $n\alpha$ phase shifts generated by the selected $^5\text{He}$ eigenstates $E_0$ obtained in NCSM with $4 \leq N_{\text{max}} \leq 6$. See Fig. 21 for details.
that by using only 10 small-$N_{\text{max}}$ eigenstates from the shaded area we accurately ‘predict’ the energies of many higher-$N_{\text{max}}$ eigenstates: the rms deviation $\Xi$ of energies of all 60 manually selected eigenstates is 92 keV (see Table IV). Of course, 92 keV is much larger than the $\Xi$ value of 11 keV obtained in the full fit to all these 60 eigenenergies, but it is still an indication of a good quality ‘prediction’ of many-body eigenenergies $E_0$ obtained with much larger bases in a wide range of $\hbar \Omega$ values.

C. Partial wave $\frac{1}{2}^+$

In this subsection we examine a possibility to describe neutron-nucleus non-resonant scattering using as input for the SS-HORSE analysis the results of many-body shell model calculations. The SS-HORSE fit is done in the same manner as in the case of resonant scattering. The difference is that the non-resonant low-energy $n\alpha$ scattering phase shifts in the $\frac{1}{2}^+$ state are described by Eq. (47) instead of Eq. (48) which parameters are fitted using Eq. (54) instead of Eq. (51). The parameter $E_b$ of this equation mimics the Pauli-forbidden state in the $n\alpha$ scattering. As compared with the discussion of the $\frac{1}{2}^+$ scattering by the model WSBG potential which supports the Pauli-forbidden state, this bound state does not appear as a result of the NCSM $^5$He calculations. Therefore we should use for the SS-HORSE fit the lowest $\frac{1}{2}^+$ state obtained by the NCSM with the eigenenergy $E_0$ and set $\nu = 0$ in Eq. (54).

These lowest $\frac{1}{2}^+$ $^5$He eigenstates $E_0$ are shown as functions of $\hbar \Omega$ for various $N_{\text{max}}$ in Fig. 42 and as a function of the scaling parameter $s$ in Fig. 43. We see a tendency of eigenstates to approach the common curve at smaller $\hbar \Omega$ values with increasing $N_{\text{max}}$ which signals that the convergence is achieved at smaller energies in larger basis spaces. This tendency is much more pronounced in the plot of the SS-HORSE phase shifts corresponding to the NCSM eigenstates in Fig. 44. This figure however also clearly indicates the need to select eigenstates for the SS-HORSE fitting.

We start with selecting eigenstates according to the inequality $\Lambda > 600 \text{ MeV}/c$ as is illustrated by Figs. 42 and 45, the respective phase shifts are shown in Fig. 46, and the obtained fitting parameters are presented in Table V. We obtain a reasonable accuracy of the fit with the rms deviation of the fitted energies of 85 keV. We reproduce reasonably the phase shift behaviour by the JISP16 $NN$ interaction. We note that at energies $E_{\text{cm}} > 25 \text{ MeV}$ the fit by Eq. (47) of the results of the phase shift analysis start going up with the energy. This seems unphysical, however the $\frac{1}{2}^+$ phases extracted from the $n\alpha$ scattering data are available only up to $E_{\text{cm}} = 20 \text{ MeV}$; the
TABLE V. $\frac{1}{2}^+ n\alpha$ scattering from the $^5$He NCSM calculations with JISP16 $NN$ interaction: fitting parameters $E_b$, $c$, $d$ and $f$ of Eq. (54), rms deviation of fitted energies $\Xi$ and the number of these fitted energies $D$ for different selections of eigenvalues in comparison with the fit by Eq. (47) of the phase shifts $\delta_0$ extracted from experimental data in Ref. [52]. For the $5 \leq N_{\text{max}} \leq 7$ selection, $\Xi$ and $D$ for all energies from the manual selection are shown within brackets.

| Selection | $E_b$ (MeV) | $c$ (MeV$^{-2}$) | $d \cdot 10^5$ (MeV$^{-2}$) | $f \cdot 10^5$ (MeV$^{-2}$) | $\Xi$ (keV) | $D$ |
|-----------|-------------|----------------|-----------------------------|-----------------------------|-------------|-----|
| $\Lambda > 600$ MeV/c | $-5.996$ | $-0.171$ | $-8.02$ | $6.48$ | $85$ | $41$ |

Phase shift analysis at higher energies is needed to obtain a more realistic fit in this energy interval where the NCSM-SS-HORSE phase shifts look more realistic.

Figure 42 demonstrates that it would be reasonable to perform a manual selection and to include in the fit more eigenstates thus extending the energy interval of the fitted phase shifts. Our manual selection of the lowest $\frac{1}{2}^+$ $^5$He eigenstates and the respective phase shifts are presented in Figs. 47, 48, 49 and Table V. Some of the fitting parameters are profoundly altered due to the inclusion of additional eigenstates in the fit, however the resulting phase shifts are nearly the same with an exception of the energies $E_{\text{cm}} > 30$ MeV where these additional eigenstates push the phase shifts slightly up. The phase shift analysis is unavailable at these energies, therefore it is impossible to judge whether this adjustment of the phase shifts improves the description of the experiment.

It is interesting and important to examine the possibility of describing the eigenenergies and non-resonant phase shifts obtained in many-body calculations in large basis spaces by SS-HORSE fits based on results in much

FIG. 45. The $^5$He $\frac{1}{2}^+$ eigenstates $E_0$ selected according to $\Lambda > 600$ MeV/c as a function of the scaling parameter $s$. See Fig. 11 for other details.

FIG. 46. The $\frac{1}{2}^+$ $n\alpha$ phase shifts generated by the $\Lambda > 600$ MeV/c selected $^5$He eigenstates $E_0$ (symbols). The solid curve depicts the phase shifts of Eq. (47) with parameters $E_b$, $c$, $d$ and $f$ obtained by the fit with this selection of eigenstates; stars and the dashed curve depict the phase shift analysis of experimental data of Refs. [52] and the fit by Eq. (47).

FIG. 48. Manually selected $^5\text{He} \frac{1}{2}^+$ eigenstates $E_0$ plotted as a function of the scaling parameter $s$ (symbols). See Fig. 11 for details.

FIG. 49. The $\frac{1}{2}^+$ $n\alpha$ phase shifts generated by the manually selected $^5\text{He}$ eigenstates $E_0$. See Fig. 46 for details.

FIG. 50. The lowest $^5\text{He} \frac{1}{2}^+$ eigenstates $E_0$ (symbols) and their $5 \leq N_{\text{max}} \leq 7$ selection (shaded area). See Fig. 10 for more details.

FIG. 51. Selected lowest $^5\text{He} \frac{1}{2}^+$ eigenstates $E_0$ obtained in NCSM with $5 \leq N_{\text{max}} \leq 7$ as a function of the scaling parameter $s$. See Fig. 11 for details.

FIG. 52. The $\frac{1}{2}^+$ $n\alpha$ phase shifts generated by the selected $^5\text{He}$ eigenstates $E_0$ obtained in NCSM with $5 \leq N_{\text{max}} \leq 7$. See Fig. 46 for details.

smaller basis spaces. As in the case of $\frac{1}{2}^-$ states, we do not succeed by choosing the eigenstates from the smallest available NCSM basis spaces with $N_{\text{max}} = 3$ and 5: note, in both cases the results from the smallest basis space with $N_{\text{max}} = 2$ for $\frac{1}{2}^-$ and $N_{\text{max}} = 3$ for $\frac{1}{2}^+$ states are not included in our respective manual selections. However picking up eigenstates obtained with $5 \leq N_{\text{max}} \leq 7$ from the manual selection of the $^5\text{He} \frac{1}{2}^+$ eigenstates, we obtain reasonable phase shifts and ‘predictions’ for the eigenstates with larger $N_{\text{max}}$, see Figs. 50, 51 and 52. It is interesting that we get similar phase shifts with three different selections of the $\frac{1}{2}^+$ eigenstates while the respective fitting parameters shown in Table V differ essentially. The rms deviation of all 53 manually selected $\frac{1}{2}^-$ eigenstates resulting from the fit to 13 eigenstates
from the $5 \leq N_{\text{max}} \leq 7$ selection is 259 keV that is much worse than the ‘predictions’ of the odd parity eigenstates. We suppose that this is related to the fact that the $\frac{1}{2}^+$ eigenstates lie higher in energy than the $\frac{3}{2}^-$ and $\frac{1}{2}^-$ eigenstates and the SS-HORSE fits, especially those to the small-$N_{\text{max}}$ eigenstates, involve the phase shifts at higher energies where our low-energy phase shift expansions become less accurate and require higher order terms in Taylor series and more fitting parameters.

V. CONCLUSIONS

We develop a SS-HORSE approach allowing us to obtain low-energy scattering phase shifts and resonance energy and width in variational calculations with the oscillator basis, in the nuclear shell model in particular. The SS-HORSE technique is based on the general properties of the oscillator basis and on the HORSE (J-matrix) formalism in scattering theory, it utilizes general low-energy expansions of the S-matrix including the poles associated with the bound and resonant states.

The SS-HORSE approach is carefully verified using a model two-body problem with a Woods–Saxon type potential and is shown to be able to obtain accurate scattering phase shifts and resonance energy and width even with small oscillator bases. Next the SS-HORSE method is successfully applied to the study of the $n\alpha$ scattering phases and resonance based on the NCSM calculations of $^5\text{He}$ with the realistic JISP16 NN interaction.

Within the SS-HORSE approach we obtain and generalize to the states lying above nuclear disintegration thresholds the scaling property of variational calculations with oscillator basis suggested in Refs. [2, 3] which states that the eigenenergies do not depend separately on $\hbar\Omega$ and the maximal oscillator quanta $N$ of the states included in the basis but only on their combination $s$ (or the scaling parameter $\lambda_{sc}$ as suggested in Refs. [2, 3], $s \sim \lambda_{sc}^2$). We demonstrate a typical behavior of eigenstates in the continuum as functions of $s$ in cases when the system has or does not have a low-energy resonance. The scaling property is useful for extrapolating the results obtained in smaller basis spaces to larger bases, and we demonstrate using both the model problem and many-body NCSM calculations that we are able to ‘predict’ accurately the eigenenergies obtained in large bases using the results from much smaller calculations.

We anticipate that the suggested SS-HORSE method will be useful in numerous shell model studies of low-energy nuclear resonances.

We plan to extend the SS-HORSE approach to the case of scattering of charged particles in future publications. We intend also to examine an application of the SS-HORSE method to the study of $S$-matrix poles corresponding to bound states and to develop the SS-HORSE extrapolation of the variational bound state energies to the infinite basis space.
