Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Structural and functional significance of the amino acid differences Val\textsubscript{35}Thr, Ser\textsubscript{46}Ala, Asn\textsubscript{65}Ser, and Ala\textsubscript{94}Ser in 3C-like proteinases from SARS-CoV-2 and SARS-CoV

SARS-CoV-2

A B S T R A C T

Three dimensional structures of (chymo)trypsin-like proteinase (3CL\textsuperscript{pro}) from SARS-CoV-2 and SARS-CoV differ at 8 positions. We previously found that the Val\textsubscript{35}Leu, Lys\textsubscript{65}Arg, Phe\textsubscript{134}His, and Asn\textsubscript{180}Lys mutations in these enzymes can change the orientation of the N- and C-terminal domains of 3CL\textsuperscript{pro} relative to each other, which leads to a change in catalytic activity. This conclusion was derived from the comparison of the structural catalytic core in 169 (chymo)trypsin-like proteinases with the serine/cysteine fold. Val\textsubscript{35}Thr, Ser\textsubscript{46}Ala, Asn\textsubscript{65}Ser, and Ala\textsubscript{94}Ser mutations were not included in that analysis, since they are located far from the catalytic tetrad. In the present work, the structural and functional roles of these variable amino acids at positions 35, 46, 65, and 94 in the 3CL\textsuperscript{pro} sequences of SARS-CoV-2 and SARS-CoV have been established using a comparison of the same set of proteinases leading to the identification of new conservative elements. Comparative analysis showed that, in addition to interdomain mobility, which could modulate catalytic activity, the 3CL\textsuperscript{pro}(s) can use for functional regulation an autolytic loop and the unique Asp\textsubscript{33}-Asn\textsubscript{65} region (the Asp\textsubscript{33}-Asn\textsubscript{65} Zone) in the N-terminal domain. Therefore, all 4 analyzed mutation sites are associated with the unique structure-functional features of the 3CL\textsuperscript{pro} from SARS-CoV-2 and SARS-CoV. Strictly speaking, the presented structural results are hypothetical, since at present there is not a single experimental work on the identification and characterization of autolysis sites in these proteases.

1. Introduction

The coronavirus disease 2019 (COVID-19) pandemic, due to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), has raised many important issues for the international scientific community especially regarding the molecular mechanisms involved in the viral infection process and SARS-CoV-2 replication. In coronaviruses, there are two functionally important proteinases papain-like (PL\textsuperscript{pro}) and the (chymo)trypsin-like cysteine proteinase (3CL\textsuperscript{pro}), also known as viral main proteinase, M\textsuperscript{pro}, both belonging to the family of cysteine proteinases (https://swissmodel.expasy.org/repository/species/2697049) [1,2]. The main protease 3CL\textsuperscript{pro}, which corresponds to the coronavirus nonstructural protein 5 (NSP5), splits the central and C-terminal regions of the polyprotein at 11 conserved sites generating 11 mature viral NSPs required for viral replication and infection [3,4].

The coordinates of the three-dimensional (3D) structures of the 3CL\textsuperscript{pro}(s) from SARS-CoV (PDB ID 1UJ1) [5] and SARS-CoV-2 (PDB ID 6LU7) [6] first appeared in the Protein Data Bank (PDB [7,8]) in 2003...
A.I. Denesyuk et al.
International Journal of Biological Macromolecules 193 (2021) 2113–2120

and 2020, respectively. These two viral proteases differ in their amino acid sequence at 12 positions: Thr125Val, Ala136Ser, Ser138Asn, Leu186Val, Arg202Lys, Ser204Ala, His234Phe, Lys285Asn, Leu285Val, Ala286Ser, Thr285Ala and Ile286Leu [9,10]. Only the first 8 out of the 12 variable amino acids are resolved in the (chymo)trypsin-like 3D structures, whereas the last 4 amino acid positions – 202, 267, 285, and 286 – belong to an additional C-terminal extension that forms domain, but which lies outside the solved 3D structure of the 3CLpro. The sequence differences at these 12 amino acid positions are not expected to significantly affect the polarity and hydrophobicity of SARS-CoV-2 3CLpro compared to 3CLpro from SARS-CoV [9]. It is of importance that all 12 variable amino acids are located outside of the catalytic and substrate binding regions of the enzyme.

During 2020–2021, structural information from X-ray structures for more than 300 SARS-CoV-2 3CLpro complexes with various inhibitor molecules were reported (https://swissmodel.expasy.org/repository/species/2697049). In addition, the 3D structures of complexes of SARS-CoV-2 3CLpro with 33 known and potential inhibitor molecules have been studied using computational methods in order to discover potential inhibitors that can be used as antiviral therapeutic agents targeting the (chymo)trypsin-like cysteine protease [11]. As a result, numerous ligand-binding amino acids of SARS-CoV-2 3CLpro have been identified. However, only 2 (Ser204 and Leu286) amino acids of the above mentioned 12 variable residue positions are mentioned in the review [11].

Motivated by the lack of insights on any structural and functional consequences of these amino acid differences at the aforementioned 12 positions in the sequences of the 3CLpro of SARS-CoV and SARS-CoV-2, we first identified the Structural Catalytic Core (SCC) in 169 (chymo)trypsin-like proteases with serine/cysteine fold [12,13]. Next, we compared the NBCZone(s) of the 3CLpro of SARS-CoV [13] and SARS-CoV-2 [12], and found that these NBCZones of both viral proteases form compact structures around the catalytic nucleophile and base that consist of 11 conserved amino acids: Leu29, Asn82, Cys83, Pro89, Arg460, His841 (catalytic base), Val424, Cys454 (catalytic nucleophile), Gly456, Ser457 and His516. Furthermore, it turned out that the NBCZones of 3CLpro of the SARS-CoV-2 (PDB ID 7BOY) [6] and SARS-CoV (PDB ID 6XHN) [14] are identical to each other [12].

The NBCZone is only a part of the SCC. Therefore, the structural regions around the third (Cys85) and fourth (His164) members of the structural catalytic tetrad have been analyzed as well [12]. The compact complex of four amino acids around the catalytic acid analogue Cys85 is referred to as 102-core. ‘T’ indicates that the canonical residue numbering based on the trypsin sequence is used; in this case referring to the third member of the structural catalytic tetrad, the catalytic Asp102 in trypsin (PDB ID 4BHH) [15]. In our work, for each protease we used both the original numbering of the amino acid sequence and the canonical numbering based on trypsin. Consequently, the 102-core and 85-core of 3CLpro of SARS-CoV-2 consists of Gln83, Cys85, Val86 and Leu89. In SARS-CoV 3CLpro, leucine replaces valine at position 86. The inclusion of the four amino acids of the 102-core in the SCC composition made it possible to reveal one more important difference between the 3CLpro of SARS-CoV-2 and SARS-CoV: Lys38Arg. This amino acid position – 88 (105β) – is located at the conserved position of the β-sheet of the N-terminal β-barrel [16].

A set of six amino acids at positions 134, 135, 136, 180, 181, and 182, located spatially next to the fourth member of the structural catalytic tetrad, His164, is referred to as the S-Core [12]. The S-Core from the 3CLpro of SARS-CoV-2 and SARS-CoV are characterized by two amino acid differences: Phe142His and Asn195Lys. These amino acids form a part of the SCC, but they are located on its periphery. The tertiary structures of (chymo)trypsin-like proteases with the serine/cysteine fold are separable into groups on the basis of the super-secondary structure differences within this region [12].

Amino acids at positions 86 and 180 are involved in the contacts between the N- and C-terminal β-barrels of the 3CLpro. The sequence differences between the SARS-CoV-2 and SARS-CoV 3CLpro’s at positions 86 and 180 seem to affect the nature of the interaction between N- and C-terminal β-barrels, which ultimately leads to the modulation of enzymatic activity [12].

These results made it possible to explain the structural and functional significance of 4 (positions 86, 88, 134 and 180) out of 8 observed amino acid differences in the SARS-CoV-2 and SARS-CoV 3CLpro sequences [12]. In the present work, we compared distinct 3D structures of 170 (chymo)trypsin-like proteases with the serine/cysteine fold, identified new conserved elements, and established the structural and functional roles of the remaining four variable amino acids at positions 35, 46, 65 and 94 in the amino acid sequences of SARS-CoV-2 and SARS-CoV 3CLpro, for which the structural context has been reported. It has been suggested that these 4 positions are associated with the autolysis process in two loops of the 3CLpro of SARS-CoV-2 as shown for trypsin and chymotrypsin proteases [17–19]. Currently, a strategy for inhibiting serine/cysteine proteases by targeting its autolysis loops is actively developing [20].

Therefore, the goal of this study was to find some important regularities in the 3D structures of the family of (chymo)trypsin-like serine/cysteine proteases (including 3CLpro (chymo)trypsin-like proteases from SARS-CoV-2 and SARS-CoV), which are currently missing in the structural description of these proteins and which can be used to answer some functional questions. To this end, we utilized a structural biology approach based on the multiple structural comparison and subsequent analysis. Earlier, application of this analysis revealed the presence in the alpha/beta-hydrolases of unique structural motifs termed the structural catalytic zones (SCZs) and the SCCs that serve to properly position the catalytic machinery and coordinate function. The advantage of the use of the SCZs and SCCs for the comparative analysis is in the capability of this approach to compare and group proteins without making superposition of their entire tertiary structures. Therefore, this approach provides useful means to classify proteins into various groups on the basis of such local structural similarities. Earlier, this analysis revealed that all proteases with the (chymo)trypsin-like serine/cysteine fold contain a universal 3D structural motif in their structural catalytic cores, the Nucleophile-Based Catalytic Zone (NBCZone), that includes eleven amino acids near the catalytic nucleophile and base [12]. We also analyzed in detail the peculiarities of the amino acid content of the SCCs in 169 proteases with the (chymo)trypsin-like serine/cysteine fold [12,13]. This analysis revealed that based on the differences in their SCCs, these proteases can be divided into two classes and four groups, with the proteases belonging to different classes and groups differing from each other by the nature of the interaction between their N- and C-terminal β-barrels. The utility of this approach for gaining important information of the functional peculiarities of proteins was proven by the comparative analysis of the 3CLpro (s) from SARS-CoV-2 and SARS-CoV, which showed that amino acids at positions 103γ and 179γ affect the nature of the interaction of the “catalytic acid” core (102γ-core, N-terminal β-barrel) with the “supplementary” core (S-Core, C-terminal β-barrel), which ultimately results in the modulation of an enzymatic activity. It was also found that the Val105Leu, Lys285Arg, Phe142His, and Asn195Lys mutations in these enzymes can change the orientation of the N- and C-terminal domains of 3CLpro relative to each other, which leads to a change in catalytic activity [13]. However, Val105Thr, Ser136Ala, Asn195Ser, Ala180Ser mutations were not included in the previous analysis, since they are located far from the catalytic tetrad. In the present work, we are filling this gap and are using the aforementioned structural biology approach to establish the structural and functional roles of these variable amino acids at positions 35, 46, 65, and 94 in the 3CLpro sequences of SARS-CoV-2 and SARS-CoV. A comparison of the same set of 169 proteases with the (chymo)trypsin-like serine/cysteine fold allowed us to identify new conservative elements. We found that, in addition to interdomain mobility, which could modulate catalytic activity, the 3CLpro (s) can use an autolytic loop and the unique Asp33-Asn95 region (the Asp33-Asn95 Zone) in the N-terminal domain.
Therefore, all 4 analyzed mutation sites are associated with the unique structure-functional features of the 3CL\textsuperscript{pro} from SARS-CoV-2 and SARS-CoV.

2. Results and discussion

2.1. Selection of residue Asn\textsubscript{28} of the 3CLpro SARS-CoV-2 as the starting amino acid for structural analysis

Earlier, a comparative structural analysis of 169 (chymo)trypsin-like proteases with the serine/cysteine fold was carried out. The analysis was based on the identification in each protein of an SCC near the catalytic tetrad and their subsequent comparison with each other [12,13]. However, in those studies we found only 4 amino acid sequence positions, in which 3CL\textsuperscript{pro}s from SARS-CoV-2 and SARS-CoV sequences differed from each other. Later, it became clear that coronavirus proteases modulate their enzymatic activity using amino acids that also are not located in structural proximity of the catalytic tetrad (this work).

The NBCZone of the SARS-CoV-2 3CL\textsuperscript{pro} (PDB ID 7BQY) [6], which is a part of the SCC around the catalytic nucleophile Cys\textsubscript{415} and the catalytic base His\textsubscript{416}, includes the amino acids Asn\textsubscript{28} and His\textsubscript{416} (Fig. 1A). Structural analysis of the region around His\textsubscript{416} and adjacent fourth member of the structural catalytic tetrad, His\textsubscript{414}, made it possible to elucidate the functional role of the amino acid differences at positions 86 and 180 [13].

The tertiary structure in the vicinity of Asn\textsubscript{28} has previously been subjected to rigorous structural analysis as well [12]. It has been shown that due to the presence of the Asn\textsubscript{28} side chain (position 43\textsuperscript{y}) prokaryotic and viral proteases cannot undergo a structural transition from zymogen to zyme type, which is observed in eukaryotic proteases [12]. Asn\textsubscript{28} is not directly involved in interactions with inhibitors [6]. In spite of this, mutation of Asn\textsubscript{28} to alanine disrupts dimerization (active form of enzyme) and completely inactivates the 3CLpro SARS-CoV [21]. Although Asn\textsubscript{28} is not directly involved in interactions with inhibitors [6], it has been shown that 8 out of 33 promising and potential 3CL\textsuperscript{pro} SARS-CoV-2 inhibitor molecules are in contact with the adjacent Leu\textsubscript{27} [11]. A hydrophobic contact between Val\textsubscript{21}, which follows the catalytic base His\textsubscript{414}, and Leu\textsubscript{27} can maintains the conformation of the polypeptide chain near the active site (Fig. 1A). Let us clarify that this statement is a hypothesis.

2.2. Val\textsubscript{42}-Leu\textsubscript{27} zone of 3CLpro SARS-CoV-2

In view of the importance of the Leu\textsubscript{27}-Asn\textsubscript{28} dipeptide and the Val\textsubscript{42} for the catalytic activity of the SARS-CoV-2 3CL\textsuperscript{pro}, this region of the tertiary structure; i.e., located “above” the NBCZone in Fig. 1A, has been analyzed using the Discovery Studio Modeling Environment (Dassault Systèmes BIOVIA, Discovery Studio Modeling Environment, Release 2017, San Diego: Dassault Systèmes, 2016) and the Ligand-Protein Contacts (LPC) software [22].

Visual analysis of the tertiary structure of the SARS-CoV-2 3CL\textsuperscript{pro} in the vicinity of Leu\textsubscript{27}, Asn\textsubscript{28} and Val\textsubscript{42} allowed identification of what we refer to as the “Val\textsubscript{42}-Leu\textsubscript{27} Zone” (Fig. 1A). A characteristic structural feature of the Val\textsubscript{42}-Leu\textsubscript{27} Zone is the presence of four main-chain hydrogen bonds between the two pairs of amino acids: Leu\textsubscript{27} and Val\textsubscript{42}, as well as Thr\textsubscript{41} and Val\textsubscript{42} (Table S1, row numbered 1, columns 6 and 7). These four amino acids are located at the ends of three anti-parallel \( \beta \)-strands and form the first well-structured part of the V42-L27 Zone. The second part of the Val\textsubscript{42}-Leu\textsubscript{27} Zone is the Val\textsubscript{42}-Leu\textsubscript{27} loop, which is also called loop B [23] or 60-loop [24]. If Leu\textsubscript{42} belongs to the “first” \( \beta \)-strand in Fig. 1A, then Val\textsubscript{42} belongs to the third \( \beta \)-strand, which is parallel to the first \( \beta \)-strand in the \( \beta \)-sheet. As noted above, the hydrophobic contact between Val\textsubscript{42} and Leu\textsubscript{27} unites two structurally dissimilar parts of the Val\textsubscript{42}-Leu\textsubscript{27} Zone into a single compact structure. Note that Val\textsubscript{42} and Leu\textsubscript{27} of the Val\textsubscript{42}-Leu\textsubscript{27} Zone are also components of the NBCZone.

Fig. 1. (A) and (B) show the “Val\textsubscript{42}-Leu\textsubscript{27} Zone” and “Cys\textsubscript{414}-Cys\textsubscript{442} Zone” of the SARS-CoV-2 3CL\textsuperscript{pro} and Trypsin Bos Taurus, respectively. S8\textsubscript{1}–42\textsubscript{1} Zone is the representative zone for 148 (chymo)trypsin-like proteinases with serine/cysteine fold. S8\textsubscript{1}–42\textsubscript{1} Zone consists of the two parts: well-structured (four hydrogen bonds) part, which consists of the residues in positions 42\textsubscript{1}, 33\textsubscript{1}, 34\textsubscript{1}, and 64\textsubscript{1}, and the S8\textsubscript{1}–64\textsubscript{1} loop, variable in length. The positions of the C\textsubscript{α}-atoms of the amino acids Ser\textsubscript{46} and Asn\textsubscript{48} of the SARS-CoV-2 3CL\textsuperscript{pro} (A), which have changed in comparison with the SARS-CoV 3CL\textsuperscript{pro}, are marked with large green circles. The location of the S8\textsubscript{1}–42\textsubscript{1} Zone in relation to the NBCZone formed by amino acids: 42\textsubscript{1}, 43\textsubscript{1}, 57\textsubscript{1} (catalytic base), 58\textsubscript{1}, 195\textsubscript{1} (catalytic nucleophile), 196\textsubscript{1}, 197\textsubscript{1}, and 213\textsubscript{1} is also shown. Some variations in the organization of the well-structured part of the S8\textsubscript{1}–42\textsubscript{1} Zone: (C) shows 3D complex of the NS3 protease and NS4A cofactor (brown); (D) 3CL-like viral cysteine protease shows another variant of structural organization of the well-structured part of the S8\textsubscript{1}–42\textsubscript{1} Zone. The second and third \( \beta \)-strands are connected by aromatic residues; (E) instead of four hydrogen bonds, only two remained in this variant of the S8\textsubscript{1}–42\textsubscript{1} Zone; and (F) The 2A proteinase has no structural analogue of the S8\textsubscript{1}–42\textsubscript{1} Zone at all. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)

2.3. S8\textsubscript{1}–42\textsubscript{1} zone of (chymo)trypsin-like proteinases with the serine/cysteine fold

The SARS-CoV-2 3CL\textsuperscript{pro} structure is one of 170 structures studied by us that have the same b.47 fold classification within the Structural Classification of Proteins–extended (SCOPe) (https://scop.berkeley.edu [25]). The tertiary structure of trypsin (PDB ID 4IBH) [15] is a representative example of this fold. Val\textsubscript{42} and Leu\textsubscript{27} of the SARS-CoV-2
3CL\textsuperscript{pro} structurally correspond to Cys\textsubscript{58} and Cys\textsubscript{42} of trypsin, respectively (Fig. 1B). Visual analysis of the tertiary structure of trypsin in the vicinity of Cys\textsubscript{42}, Gly\textsubscript{43}, and Cys\textsubscript{58}, allowed identification of the “Cys\textsubscript{58}-Cys\textsubscript{42} Zone”, whose characteristic structural feature is the presence of four main-chain hydrogen bonds between two pairs of amino acids: Cys\textsubscript{42} and Leu\textsubscript{43}, as well as Asn\textsubscript{134} and Gln\textsubscript{164} (Table S1, row numbered 13, columns 6 and 7).

At first glance, the Val\textsubscript{42}-Leu\textsubscript{27} and Cys\textsubscript{58}-Cys\textsubscript{42} Zones are structurally similar (see Fig. 1A and B). However, one can see two fundamental differences. The hydrophobic contact between Val\textsubscript{42} and Leu\textsubscript{27} that closes the Val\textsubscript{42}-Leu\textsubscript{27} Zone is replaced by the Cys\textsubscript{58}-Cys\textsubscript{42} disulfide bond, which is conserved in eukaryotes [12]. The second significant difference between the two zones is the different lengths of the Val\textsubscript{42}-Leu\textsubscript{27} and Cys\textsubscript{58}-Gln\textsubscript{164} loops: 26 and 7 residues, respectively (Table S1, rows numbered 1 and 13, column 9).

The Val\textsubscript{42}-Leu\textsubscript{27} Zone for the 3CL\textsuperscript{pro} SARS-CoV-2 can be also written in a universal form as the 58\textsubscript{8}–42\textsubscript{Z} Zone. Unlike prokaryotic and viral proteases, most eukaryotic proteases have disulfide-linked cysteines at positions 42\textsubscript{T} and 58\textsubscript{T} [12]. The need for a strong side-chain interaction forming the single ring-shaped structure (Zone) is apparently directly related to the functioning of eukaryotic proteases. In fact, it has been shown that the presence or absence of the Cys\textsubscript{42}–Cys\textsubscript{58} disulfide bond affects the overall thermal stability of trypsin [26].

The results of the structural analysis of the 58\textsubscript{8}–42\textsubscript{Z} Zone for all 170 structures are presented in Table S1. 148 structures (Table S1, rows numbered 1–148) have an identical structural organization of the first well-structured part of the 58\textsubscript{8}–42\textsubscript{Z} Zone. This large group of proteases includes all eukaryotic and prokaryotic proteases, TA and [KR]P groups of the viral serine proteases, [TA]N and [ΨC][PQ] groups of the viral cysteine proteases and inactive proteases. The names of the groups and the list of the corresponding proteases are taken from the study on the characterization of the NBCZones in (chymo)trypsin-like proteinases with the serine/cysteine fold [12]. The [ΨC][PQ] group includes twelve viral cysteine proteases, which lack the catalytic acid [13]; i.e., instead of the catalytic triad, they have a catalytic dyad in the active site (Table S1, rows numbered 1–12). Eleven out of twelve proteins are coronavirus proteases. It is important to note that, despite the structural identity of the well-structured part of the 58\textsubscript{8}–42\textsubscript{Z} Zone of this group of 148 proteases, the 58\textsubscript{8}–64\textsubscript{Z} loop varies significantly in length from 4 to 37 residues (Table S1, column 9).

Some variation in the organization of the well-structured part of the 58\textsubscript{8}–42\textsubscript{Z} Zone is demonstrated by the proteases belonging to the viral serine proteases, [ST]\textsuperscript{P} group (Table S1, rows numbered 149–156). Unlike the 148 proteases considered earlier, the PDB files of 8 proteases belonging to this group contain non-covalent, heterodimer complexes formed by two proteins, the N-terminal serine protease domain of NS3 (catalytic subunit) and the NS4A cofactor (activation subunit) and the NS4A cofactor (activation subunit). The formation of a heterodimeric complex results in a structure, where a β-strand from NS4A (brown in Fig. 1C) is located in the Gly\textsubscript{1508}–Phe\textsubscript{1043} Zone for the complex of the NS3 protease and NS4A protein from the hepatitis C virus (PDB ID 3SU6) [27]. The formation of a heterodimeric complex results in a structure, where a β-strand from NS4A (brown in Fig. 1C) is located in the Gly\textsubscript{1508}–Phe\textsubscript{1043} Zone for the complex of the NS3 protease and NS4A protein from the hepatitis C virus (PDB ID 3SU6) [27]. The formation of a heterodimeric complex results in a structure, where a β-strand from NS4A (brown in Fig. 1C) is located in the Gly\textsubscript{1508}–Phe\textsubscript{1043} Zone for the complex of the NS3 protease and NS4A protein from the hepatitis C virus (PDB ID 3SU6) [27]. The formation of a heterodimeric complex results in a structure, where a β-strand from NS4A (brown in Fig. 1C) is located in the Gly\textsubscript{1508}–Phe\textsubscript{1043} Zone for the complex of the NS3 protease and NS4A protein from the hepatitis C virus (PDB ID 3SU6) [27]. The formation of a heterodimeric complex results in a structure, where a β-strand from NS4A (brown in Fig. 1C) is located in the Gly\textsubscript{1508}–Phe\textsubscript{1043} Zone for the complex of the NS3 protease and NS4A protein from the hepatitis C virus (PDB ID 3SU6) [27].

2.4. Val\textsubscript{42}-Leu\textsubscript{67} loop of 3CL\textsuperscript{pro} SARS-CoV-2

The Val\textsubscript{42}-Leu\textsubscript{67} loop of the SARS-CoV-2 3CL\textsuperscript{pro} contains 26 amino acids (Table S1, row numbered 1, columns 8 and 9) and the residues at positions 46 and 65 (Figs. 1A and 2A) were the subject of our structural analysis. This loop is long and contains 2 of 8 positions, in which amino acid residues are different in the 3CL\textsuperscript{pro}s from SARS-CoV-2 and SARS-CoV. Therefore, we studied the structural and functional role of this loop. Since the 58\textsubscript{8}–64\textsubscript{Z} loop length in 170 proteases varies significantly from 4 to 37 residues, it was impossible to compare them structurally. For this reason, we analyzed structural and functional role of the Val\textsubscript{42}-Leu\textsubscript{67} (58\textsubscript{8}–64\textsubscript{T}) loop of the SARS-CoV-2 3CL\textsuperscript{pro}.

Fig. 2. (A) Hydrophobic interactions (small green and orange circles) between Val\textsubscript{42}-Leu\textsubscript{67} loop and Cys\textsubscript{58}-Cys\textsubscript{42} Zone in the SARS-CoV-2 3CL\textsuperscript{pro}. The positions of the C\textsubscript{α}-atoms of the amino acids Ser\textsubscript{40} and Asn\textsubscript{42} of the SARS-CoV-2 3CL\textsuperscript{pro} (A), which have changed in comparison with the SARS-CoV 3CL\textsuperscript{pro}, are marked with large green circles. Polar contacts (small blue and green circles) between the conserved parts of the interdomain loop (IDL): Val\textsubscript{185}Gln\textsubscript{192}, Horse Shoe-Shaped Region (HSSR) and Val\textsubscript{42}-Leu\textsubscript{67} loop. (B) In the complex between ligand and SARS-CoV-2 3CL\textsuperscript{pro} hydrophobic amino acids Cys\textsubscript{444}, Met\textsubscript{469} and Tyr\textsubscript{554} of the Val\textsubscript{42}-Leu\textsubscript{67} loop and the Leu\textsubscript{4} residue of the ligand interact with each other and maintain the 3D position of the catalytic histidine in position 41. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)
2.4.1. Hydrophobic interactions between the Val\textsubscript{142}-Leu\textsubscript{167} loop and Cys\textsubscript{85}-zone

The tertiary conformation of the Val\textsubscript{142}-Leu\textsubscript{167} loop is stabilized by numerous hydrophobic contacts of the amino acids Val\textsubscript{142}, Ile\textsubscript{143}, Tyr\textsubscript{154}, Leu\textsubscript{166}, and Phe\textsubscript{166} with the N- and C-terminal hydrophobic amino acids Met\textsubscript{66} and Leu\textsubscript{67} of the Cys\textsubscript{85}-Zone (Fig. 2A). The Cys\textsubscript{85}-Zone is actually a structural analogue of the catalytic acid (position 102\textsubscript{T}) zone) [13]. With a few exceptions, a similar type of interactions between the S8–64\textsubscript{T} loop and 102\textsubscript{T}-Zone is typical for all (chymo)trypsin-like proteinases with the serine/cysteine fold (data not shown).

The mutation Asn\textsubscript{65}Ser of the SARS-CoV-2 3CL\textsuperscript{pro} is located near the C-terminal end of the Val\textsubscript{142}-Leu\textsubscript{167} loop. Positions 65 and 66 are adjacent in the amino acid sequence, therefore, it can be reasonably assumed that Asn\textsubscript{65}Ser sequence difference would affect the contact between the Val\textsubscript{142}-Leu\textsubscript{167} loop and the Cys\textsubscript{85}-Zone through the amino acid Phe\textsubscript{66}. The change in the nature of this contact compared to homologous contact in the 3CL\textsuperscript{pro} of the SARS-CoV is caused both by a change in the size of the side chain group of the amino acid at position 65 and by the appearance of an additional positively charged group of NH\textsubscript{2} atoms.

2.4.2. The N-end half of the Val\textsubscript{142}-Leu\textsubscript{167} loop interacts with ligand

An analysis of contacts in the complex (PDB ID 7BQY) between the PRD 002214 ligand and SARS-CoV-2 3CL\textsuperscript{pro} performed by means of the LPC software [22] showed that Cys\textsubscript{44}, Met\textsubscript{49}, and Tyr\textsubscript{54} of the Val\textsubscript{142}-Leu\textsubscript{167} loop and residue Leu\textsubscript{4} of the ligand interact with each other and maintain the 3D positioning of the catalytic histidine at the sequence position 41 mainly via hydrophobic interactions (Fig. 2B).

These results are consistent with the data presented in the recent review of application of various computational methods (see Table 1 in [11]) for the identification of amino acids that are involved in contacts between 33 antiviral ligands and the SARS-CoV-2 3CL\textsuperscript{pro}. Compared to other residues of the Val\textsubscript{142}-Leu\textsubscript{167} loop, Met\textsubscript{49} (17 of 33 cases) and Tyr\textsubscript{54} (8 of 33 cases) are the most frequently observed as residues participating in contacts. Therefore, the N-terminal half of the Val\textsubscript{142}-Leu\textsubscript{167} loop is responsible for modulating the catalytic activity of the SARS-CoV-2 3CL\textsuperscript{pro}. Let us clarify that this statement is a hypothesis. It is possible that the observed replacement of the hydrophobic amino acid alanine of in the SARS-CoV-2 3CL\textsuperscript{pro} by the polar serine at position 46 will affect this modulation. Ser\textsubscript{46} and Met\textsubscript{49} are located on a short, one-turn α-helix Thr\textsubscript{45}-Met\textsubscript{48}. The side-chains of Ser\textsubscript{46} and Met\textsubscript{49} groups are in tight contact with each other. Apparently, Met\textsubscript{48} is a key intermediate amino acid, through which a change in the residue at position 46 affects the catalytic base.

Fig. 3 shows the structural alignment of the Val\textsubscript{142}-Leu\textsubscript{167} loop from the SARS-CoV-2 3CL\textsuperscript{pro}, with loops from ten coronavirus proteases and the loop of one 3CL protease from the Cavally virus (Table S1, rows numbered 1–12). The alignment was built using the Protein Structure Comparison Server Dali [34]. The length of loops in coronavirus proteases corresponding to the Val\textsubscript{142}-Leu\textsubscript{167} loop of the SARS-CoV-2 3CL\textsuperscript{pro} is fairly uniform and varies from 23 to 26 amino acids (Table S1, columns 8 and 9). It is important to note that the alignment contains deletions at the N-terminus within a narrow range of positions 45–48 (SARS-CoV-2 3CL\textsuperscript{pro} numbering). Therefore, the use of the position 46 to modulate the catalytic activity of coronavirus proteases is quite possible.

2.4.3. The N-end half of the Val\textsubscript{142}-Leu\textsubscript{167} loop interacts with the N-terminus of the interdomain loop (IDL)

The SARS-CoV-2 3CL\textsuperscript{pro} structure is comprised of two β-barrels (domains I and II), bringing the catalytic residues together at their interface (canonical (chymo)trypsin-like structure, residues Ser\textsubscript{1}, Asp\textsubscript{176}, and an additional C-terminal extension [6]. Asp\textsubscript{176} is the last amino acid of the H156-Core [13]. The C-terminal extension that starts with Leu\textsubscript{177} contains interdomain loop (IDL, residues 184–199) (Fig. 2A). The conserved Val\textsubscript{180}–Gln\textsubscript{192} Horse-Shoe-Shaped Region (HSSR) is a part of the IDL [35]. Asp\textsubscript{176} and the water molecule HOH\textsubscript{190} compensate for the absence of catalytic acid in the SARS-CoV-2 3CL\textsuperscript{pro} (Fig. 2A). The residues Ser\textsubscript{46}, Met\textsubscript{49}, Leu\textsubscript{50}, Pro\textsubscript{52}, and Tyr\textsubscript{54} of the Val\textsubscript{142}-Leu\textsubscript{167} loop are in contact with Asp\textsubscript{176}, Arg\textsubscript{188}–Gln\textsubscript{192} and Thr\textsubscript{190} of the IDL. It has been suggested that the IDL may represent a regulatory site, since it does not contain the amino acids of the catalytic triad [35].

Therefore, the Ser\textsubscript{46}Ala sequence difference between the SARS-CoV-2 and SARS-COV 3CL\textsuperscript{pro} located near position 58\textsubscript{T}, can affect the catalytic activity of the SARS-CoV-2 3CL\textsuperscript{pro} not only by itself, but also indirectly through the IDL C-terminal extension. As noted above, the residue Ser\textsubscript{46} is an essential functional element affecting the binding process of the ligand [11,36]. It was also suggested that the mutation Ser\textsubscript{46}Ala may increase the contribution of other hydrophilic amino acids to the structure of the active site [37].

2.4.4. Ser\textsubscript{46}Ala and Asn\textsubscript{65}Ser, and probable autolysis regulation in the SARS-CoV-2 3CL\textsuperscript{pro}

There is another possibility related to the functional consequences of the Ser\textsubscript{46}Ala and Asn\textsubscript{65}Ser sequence differences between the SARS-CoV-2 and SARS-COV 3CL\textsuperscript{pro} proteins. Dissolved trypsin is known to undergo autolytic degradation [17]. Three important autolysis sites have been reported for bovine trypsin: Lys\textsubscript{55}–Ser\textsubscript{56}, Arg\textsubscript{117}–Val\textsubscript{118} and Lys\textsubscript{145}–Ser\textsubscript{146}. In rat (chymo)trypsin the autolytic site Phe\textsubscript{60} can affect the catalytic activity of the SARS-CoV-2 3CL\textsuperscript{pro} not only by itself, but also indirectly through the IDL C-terminal extension. As noted above, the residue Ser\textsubscript{46} is an essential functional element affecting the binding process of the ligand [11,36]. It was also suggested that the mutation Ser\textsubscript{46}Ala may increase the contribution of other hydrophilic amino acids to the structure of the active site [37].
whether there are autolytic sites in the SARS-CoV-2 3CLpro, in which amino acid changes are observed compared to the SARS-CoV 3CLpro (PDB ID 6XHN), are located respectively at the N- and C-terminal ends of the functionally important β-strands Val35-Pro39 and Val49-Lys50 (Fig. 4A). The first of these two β-strands contains catalytic histidine His64 near its C-terminal end, and the second β-strand contains at its N-terminal Cys50 that replaces the catalytic acid. The last β-strand also contains the positions 86 and 88 where SARS-CoV-2 and SARS-CoV sequences have different amino acids. In the SARS-CoV-2 3CLpro 3D structure, these two β-strands form an antiparallel β-hairpin, held together by six interchain hydrogen bonds, starting from the bond N/Arg40–O/Cys85 (3.0 Å) and ending with the O/Asp34–N/Val81 bond (3.0 Å) (Fig. 4A). The two contacts between these fragments, being separated within the amino acid sequence, take place within the 3D structure, since two more hydrogen bonds are observed: O/Asp33–CA/ Ala94 and O/Asp32–N/Asn95. In addition, the tetrapeptide Leu22-Val35 forms a β-turn. As a result, two fragments Asp33-Asp34 and Val90-Asn95 form an Asp33-Asn95 Zone. This zone directly contains the position of interest to us: Ala94, Val35 lies at the border of the Asp32-Asn95 Zone and an antiparallel β-hairpin.

Due to the fact that positions 35 and 94 are spatially close to each other in the structure of the Asp33-Asn95 Zone from the SARS-CoV-2 3CLpro, it was of interest to analyze the equivalent region from all the 3D structures included in the superfamily of (chymo)trypsin-like proteinases with the serine/cysteine fold. The results of the analysis of 128 proteinases (75% of the total set) are collected in Table S2. In the structure of trypsin, the amino acids Ser49 and Ala112 respectively correspond to the Asp33 and Asn95 of the SARS-CoV-2 3CLpro (Fig. 4B).

The two remaining positions 35 and 94 of the SARS-CoV-2 3CLpro (PDB ID 7BQY), in which amino acid changes are observed compared to the SARS-CoV 3CLpro (PDB ID 6XHN), are located respectively at the N- and C-terminal ends of the functionally important β-strands Val35-Pro39 and Val49-Lys50 (Fig. 4A). The first of these two β-strands contains catalytic histidine His64 near its C-terminal end, and the second β-strand contains at its N-terminal Cys50 that replaces the catalytic acid. The last β-strand also contains the positions 86 and 88 where SARS-CoV-2 and SARS-CoV sequences have different amino acids. In the SARS-CoV-2 3CLpro 3D structure, these two β-strands form an antiparallel β-hairpin, held together by six interchain hydrogen bonds, starting from the bond N/Arg40–O/Cys85 (3.0 Å) and ending with the O/Asp34–N/Val81 bond (3.0 Å) (Fig. 4A). The two contacts between these fragments, being separated within the amino acid sequence, take place within the 3D structure, since two more hydrogen bonds are observed: O/Asp33–CA/ Ala94 and O/Asp32–N/Asn95. In addition, the tetrapeptide Leu22-Val35 forms a β-turn. As a result, two fragments Asp33-Asp34 and Val90-Asn95 form an Asp33-Asn95 Zone. This zone directly contains the position of interest to us: Ala94, Val35 lies at the border of the Asp32-Asn95 Zone and an antiparallel β-hairpin.

Due to the fact that positions 35 and 94 are spatially close to each other in the structure of the Asp33-Asn95 Zone from the SARS-CoV-2 3CLpro, it was of interest to analyze the equivalent region from all the 3D structures included in the superfamily of (chymo)trypsin-like proteinases with the serine/cysteine fold. The results of the analysis of 128 proteinases (75% of the total set) are collected in Table S2. In the structure of trypsin, the amino acids Ser49 and Ala112 respectively correspond to the Asp33 and Asn95 of the SARS-CoV-2 3CLpro (Fig. 4B). Fig. 4B shows the 3D organization of the Ser49-Ala112 Zone in trypsin. The first 108-112 fragment consists of 5 residues, and the second 49-50 fragment is formed by two amino acids. Therefore, the SARS-CoV-2 3CLpro and trypsin have a structurally identical Asp33-Asn95 and Ser49-Ala112 Zones, which are located far from the catalytic tetrad. In the course of the structural analysis, we identified 104 examples of such 3D sub-structures (Table S2, rows numbered 1–11, 13–79, 88–91, 104, 141–147 and 157–170). In addition to the identity of the 49–112 Zones, 104 proteases have an identical 3D arrangement of the 49–112 Zone in relation to the catalytic base at position 57 and the catalytic acid at position 102 (or its structural analog). This group of proteases was given the code name “(5 + 2).”

Eight other proteases form a (8 + 2) group (Table S2, rows numbered 133–140). Fig. 4C shows an example of the 49–112 Zone for the nuclear inclusion protein A from the Tobacco vein motting virus from a (8 + 2) group. Apparently, the presence of 8 amino acids in the first fragment of the 49–112 Zone is the maximum possible number. This conclusion is derived from the structural observations, where the extension of the first fragment only by one amino acid leads to the impossibility of the formation of contact between the Cα of the residue at position 111 and the main-chain oxygen atom of the residue in position 49. However, four proteases (Table S2, rows numbered 27, 53, 67, and 76) overcome this restriction as their 49–112 Zone is formed through the use of a disulfide bond Cys111-Cys50, thereby defining the (9 + 2) group (Fig. 4D). Further lengthening of the first fragment of the 49–112 Zone (Fig. 4E) to a (11 + 2) group results in a situation, where the disulfide bond Cys111-Cys50 is no longer used for mutual structural stabilization of the ends of the 49–112 Zone (Table S2, rows numbered 117–121).

The last seven examples of proteases in Table S2 show that the 49–112 Zone can be modified not only by changing the amino acid length of the first fragment but also by extending the second fragment by one residue. Fig. 4F shows serine protease HTRA2 from the Homo sapiens as an example of the Ala189-Leu240 Zone from such a (7 + 3) group. Four proteases have been found with a similar zone arrangement (Table S2,
rows numbered 80–82, and 148). The last three prokaryotic proteases form a (21 + 3) group (see Table S2, rows numbered 101–103) and demonstrate the variant of the zone, in which the second fragment has 3 amino acids allowing for significantly wider variations in the length of the first fragment compared to the zone, in which the second fragment has 2 amino acids.

In the Section 2.4.4, we cited the works in which Arg117-Val118 dipeptide of trypsin was mentioned as an autolysis site [18]. There appears to be a close relationship between the 49–112 Zone and the autolysis process. At positions 35 and 94, the 3CLpro SARS-CoV-2 has two small hydrophobic amino acids Val35 and Ala94 instead of two small polar residues Thr35 and Ser94 in the 3CLpro SARS-CoV. It is possible that such changes in amino acids give the 3CLpro SARS-CoV-2 structure additional hydrophobic resistance to autolysis that is amino acid replacements at positions 35 and 94 of the 3CLpro SARS-CoV-2 can change the autolysis rate. This structural assumption is hypothetical and should be verified by appropriate experiments.

3. Conclusions

The 3D structures of (Chymo)trypsin-like 3CLpro from SARS-CoV-2 and SARS-CoV have different amino acid residues at 8 positions of their amino acid sequences: Val35Thr, Ser46Ala, Asn50Ser, Val53Leu, Lys88Arg, Ala89Ser, Phe134His, and Asn180Lys (Fig. 5). These residues can be divided into two structural groups. The first group includes 4 amino acids at positions 86, 88, 134, and 180 that form the structural catalytic core. The second group includes 3 amino acids at positions 46, 65, and 94 located in the loop regions. This group is also adjoined by the amino acid at position 35. The first group of residues modulates the catalytic activity of the 3CLpro by changing the nature of the interaction between the N- and C-terminal β-barrels. The second group includes 3 amino acids at positions 46, 65, and 94 located in the loop regions (Fig. 5A and B). This group is also adjoined by the amino acid at position 35 (Fig. 5A and B). The first group of residues modulates the catalytic activity of the 3CLpro by changing the nature of the interaction between the N- and C-terminal β-barrels. The second group of residues can be involved in modulation of the activity using such unique features of the tertiary structure as the existence of the C-terminal extension (IDL loop). In addition, the amino acids of the second group and the sites of possible autolysis of the 3CLpro interact in the amino acid sequence, which suggests that the process of autolysis of proteases plays an essential role in modulating catalytic activity of this important viral protease. This result opens up a new field of scientific research for those researchers involved in protein characterization and inhibition of the 3CLpro from SARS-CoV-2.

4. Materials and methods

4.1. The choice of structures to be analysed

In this work, as in the previous publications [12,13], the same dataset of 170 3D structures of the (chymo)trypsin-like proteases with serine/cysteine fold was used. In these two publications, all the procedural details of the compilation of the required set of 3D structures are described in detail.

4.2. Modeling software for structural analysis

Structure visualization and structural analysis of interactions between amino acids in proteins (hydrogen bonds, hydrophobic, other types of weak interactions) were carried out using the Discovery Studio Modeling Environment (Dassault Systèmes BIORVIA, Discovery Studio Modeling Environment, Release 2017, San Diego: Dassault Systèmes, 2016) and the Ligand-Protein Contacts (LPC) software [22]. Figures are drawn with MOLSCRIPT [38].

Fig. 5. Superposition of three-dimensional (3D) structures of the 3CLpro(s) from SARS-CoV (PDB ID 1UJ1; shown in gray) and SARS-CoV-2 (PDB ID 6LU7; shown in blue). (A) Shows the location within the entire structure of the V42-L27 Zone (for reference, see Fig. 1A), the catalytic triad (H41, C85 and C145 in SARS-CoV-2), and the variable amino acids at the positions 35, 46, 65 and 94. (B) Shows the location of the D33-N95 Zone (for reference, see Fig. 4A), the catalytic triad (H41, C85 and C145 in SARS-CoV-2), and the variable amino acids at the positions 35, 46, 65 and 94. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)
