Abstract

Background: High level of self-efficacy and adherence to self-care activities have a positive impact on the achievement of glycemic goal among diabetic patients. In Sudan, there is a gap in knowledge related to self-efficacy management and its influence on adherence to self-care activities and overall disease control.

Objective: To identify the influence of management self-efficacy on adherence to self-care activities and treatment outcome among Sudanese patients with type 2 diabetes mellitus.

Methods: A cross-sectional study was conducted at two health care facilities in Sudan from April to May 2016. Patients with type 2 diabetes mellitus were included. Convenience sampling method was adopted. Diabetes Management Self-Efficacy Scale and the Revised Summary of Diabetes Self-Care Activities were used to collect data through a face-to-face interview. Logistic regression analysis was performed. A p value <0.05 was considered to be significant. Data were processed using the software SPSS v 21.0.

Results: A total of 392 patients were included. Respondents classified with high level of self-efficacy across all domains were 191 (48.7%). Moreover, high level of education [adjusted OR 0.5 (0.3-0.7), (p=0.001)] and formal health education on diabetes [adjusted OR 2.4 (1.6-3.7), (p=0.001)], were found to be significantly associated with high level of diabetes management self-efficacy. Patients who had high level of self-efficacy to manage nutrition, physical exercise activity and medication were found more adherent to general diet, exercise activity, and medication taking, respectively. Patients with controlled disease were 87 (22.2%). The only predictor of diabetes control was diabetes management self-efficacy [OR 2.1(1.3-3.5), (p=0.002)].

Conclusions: Diabetes management self-efficacy was associated with high level of education and receiving health education. Self-efficacy was significantly associated with adherence to self-care activities and glycemic control. Substantial efforts are still needed to empower the patients with self-efficacy and improving adherence to self-care activities through appropriate interventions.

INTRODUCTION

Diabetes mellitus (DM) is an important public health problem with a steadily increasing rate globally. In the year 2014, an estimated number of 422 million adults were living with the disease. Type 2 diabetes mellitus accounts for more than 90% of all diabetes globally.

In Sudan, a recent research conducted in urban communities revealed a high rate of diabetes among adult population (19.1%) and impaired glucose tolerance (9.5%). Diabetes represent a significant impact in term of adverse social effects and economic burden on Sudanese patients.

Achievement of the target therapeutic goals requires regular monitoring of blood sugar, strict adherence to both lifestyle measures and medications, and continuous management to prevent complications. Therapeutic goal achievement also needs a high capability to survive with the psychosocial challenges related to living with the disease and dynamically consuming pertinent diabetes support services. Multiple factors can influence glycaemic control, which can be related to the patient, the disease and the treatment. Studies around different parts of the world documented high prevalence of uncontrolled diabetes with multiple factors implicated in poor blood sugar control.

Self-care in diabetes is an evolutionary process of developing knowledge or awareness by learning to survive with the complex nature of the disease in a social context. Self-care in diabetes include seven important activities, which predict the outcome of treatment, such as eating healthy diets, practicing physical exercise, monitoring of blood sugar, adherence to medications, good problem-solving skills, healthy coping skills, and risk-reduction behavior. Self-management is considered as the foundation of diabetes care, and it is assumed that improving patient self-management could be through enhancement of self-efficacy.

Self-efficacy concerns with the people’s beliefs about their capabilities to produce designated levels of performance.
that exercise influence over events that affect their lives. Self-efficacy can be simplified by the interaction between behavioral, personal, and environmental factors in health and chronic disease. Self-efficacy has a positive influencing effect on self-management for many chronic health conditions. High self-efficacy was found to be associated with high self-care behavior among diabetic patients, and both had a direct effect on glycosylated hemoglobin (HbA1c). Conversely, in some studies, no significant association was documented between glucose control and self-efficacy or self-care. Moreover, educational status, employment status, family support, positive mental attitudes and diabetes education were found to have an influence on self-efficacy.

To the best of our knowledge, no previous study was conducted in Sudan among diabetic patients to correlate self-efficacy with self-management activities and identify the role of self-efficacy on glycemic control. Therefore, this study was conducted to identify the influence of management self-efficacy on adherence to self-care activities and treatment outcome among Sudanese patients with type 2 diabetes mellitus. Secondary objectives were: to measure the level of diabetes management self-efficacy, and to determine its predictors and to determine the level of disease control and to identify its determinants.

METHODS

Design and population

A cross-sectional study was conducted at two healthcare facilities in Khartoum State in Sudan (Jabir Abu Eliz Diabetes Centre and the Outpatient Clinic in Soba Teaching Hospital) from April to May 2018. The Outpatient clinic in Soba Teaching Hospital, which is located in the Southern part of Khartoum State, provides services for approximately 40,000 patients per year suffering from chronic diseases. Jabir Abu Eliz Diabetes Centre, located in the central part of Khartoum State, is the only public center for diabetes in the state. The Center provides a broad range of medical services for diabetic patients. The two healthcare facilities were selected as points for data collection due to their potentiality with respect to the number of patients.

The Patients aged over 20 years and diagnosed with type 2 diabetes mellitus, at least one year before commencement of data collection were included. Patients with cognitive impairment, inability to communicate verbally, pregnant or lactating women, and patients who had severe concurrent illness that limit lifestyle change were excluded. The patients consented verbally, because the research posed no risk and did not involve procedures for which written consent is normally needed. The convenience sampling method was used, because there were no well-defined registry records in both settings. The sample size was estimated to be 384 patients by using the following equation:

\[ n = \left( \frac{1.96}{D} \right)^2 pq \]

Whereas (p=Probability=0.5), (q=1-p=0.5), (D=Degree of precision=0.05, confidence level (CI)=95%).

Ethical approval for the conduction of the study was obtained from Ministry of Health – Khartoum State on 20 March 2016.

Instruments

The data was collected by the main author through face-to-face interview method using a pre-tested questionnaire. The questionnaire was developed after thoroughly searching the literature for relevant studies. Pertinent clinical parameters were extracted from the relevant patients’ records. Recent HbA1c results were extracted from the patients’ medical records. The second part was designed to collect data on patients’ self-efficacy for the management of diabetes using the Diabetes Management Self-Efficacy Scale (DMSES), which is composed of 20 items. DMSES assesses the extent to which a patient is confident that he or she can manage his/her blood glucose level (3 items), foot care (1 item), medication (2 items), diet (10 items), level of physical activity (3 items), and visiting the physician once a year for a checkup (1 item). Responses were rated using a scale ranging from 0 (can’t do at all) to 10 (certain to do) with high scores indicating high self-efficacy. High and low general diabetes management self-

| Yes                               | 45.6 | 283 |                  |         |                     |         |
| Total                             | 100 | 392 |                  |         |                     |         |

efficacy and self-efficacy at different domains were
measured as follows:
a. The patient was considered as having high level self-
efficacy if scored equal or above the mean scores of all the
participants.
b. Similarly, high level of self-efficacy at each domain
(nutrition, physical exercise and medication) was
defined as scores equal or higher than the mean score
of all patients.

The third part of the data collection tool included the
Revised Summary of Diabetes Self-care Activities (SDSCA). In
this part, the participant was requested to report the
number of days in the last 7 days in which he/she
performed each self-care activity. The activities include;
diet, exercise, blood glucose testing, medication taking,
foot care, and smoking behavior. Adherence to the
activities was defined as follows:
a. Adherence to general diet, specific diet, and physical
exercise domains was defined as adherence to the
determined self-care activity for at least 5 days during the
past week.
b. Adherence to medication was defined as full compliance
during the past week. If the patient reported less than
seven days adherence to medication, he/she was
considered as non-adherent.

The last part of the questionnaire was designed to record
glycated hemoglobin (HbA1c). Diabetes was considered
controlled if HbA1c was <7% as per both study sites
protocols. The questionnaire was piloted among ten
patients to ensure applicability and to estimate the time
frame needed for data collection. Minor changes were
suggested and finally adopted in the last version.

The questionnaire was delivered to the patients in Arabic
language. The Arabic version of DMSES and SDSCA were
used after obtaining the permission from Elbur et al. The
translation was checked further to fit the Sudanese dialect.
The research team also checked the questionnaire content
validity.

The main outcome measures in the study were: 1) The
influence of the level of diabetes management self-efficacy
on diabetes self-care activities; and 2) The influence of the
level of diabetes management self-efficacy on disease
control. Two secondary outcome measures were also
considered: 1) The level of diabetes management self-
efficacy and its predictors; and 2) The level of disease
control and its determinants.

Data analysis

Descriptive statistics were used to characterize the study
sample. Percentage and means with standard deviation
(SD) were used to describe the variables. Cronbach’s alpha
was used to examine the internal consistency of DMSES
and SDSCA. Logistic regression analysis was performed to
determine the most significant independent variables
demographic and clinical variables) associated with
diabetes self-efficacy, management, and diabetes control
as dependent variables. Crude logistic regression analysis
was performed as initial steps of qualifying covariates to be
included in multivariate logistic regression analysis.
Covariates with p-value <0.05 were eligible for inclusion in
the final model. The association between self-efficacy
management and adherence to self-care activities was
A total of 392 patients were included, with 335 (85.5%) recruited from Jahir Abu Elizz Diabetes Centre and 57 (14.5%) from Soba Teaching Hospital. Male patients were 212 (54.1%) and 250 (63.8%) aged over 50 years. More than half of the participants attained an educational level between 0-9 years and 49.7% attended formal diabetes education sessions. Obese and overweight were 250 (63.8%). Table 1 showed participants characteristics.

Out of all included patients, 211 (53.8%) had other concomitant disease. Patients suffered from hypertension were 140 (35.7%), and 119 (30.4%) had dyslipidemia. Regarding diabetes complications, 111 (28.3%) experienced retinopathy, 236 (60.2%) neuropathy, 83 (21.2%) diabetic septic foot and 12 (3.1%) nephropathy.

The internal consistency of DMSES was alpha=0.9. The mean scores of self-efficacy to manage nutrition, physical exercise and weight control and medication were 67.8 (SD 17.0), 18.6 (SD 7.3) and 18.0 (SD 3.4), respectively. The mean score of diabetes management self-efficacy across all domains was 136.8 (SD 29.7). Out of all interviewed patients, 191 (48.7%) were classified as having high self-efficacy across all domains to manage diabetes. Participants with high level of self-efficacy in nutrition management, physical exercise and weight control, and medical treatments were 188 (48.0%), 199 (50.8%) and 281 (71.7%), respectively.

Table 2 shows the determinants of diabetes management self-efficacy. Multivariate analysis showed that, education over 9 years, and receiving formal health education messages. Unemployed participants represented 59%, which in agreement with Von Arx et al. study, where most of the population was unemployed because of diabetes complications. The major observed comorbid conditions were hypertension and dyslipidemia, which might increase the microvascular and macrovascular risk in patients with diabetes, but also might increase the financial burden, which inversely could affect the adherence to medication and self-care activities. In our study, nearly half (48.7%) of all interviewees classified as having high self-efficacy across all domains to manage their diabetes, and 48.0%, 50.8% and 57 (27.9%) were classified as adherent to general diet, specific diet, physical exercise, and medication, respectively.

As shown in Table 4, patients with high self-efficacy to manage nutrition, physical exercise activity and medication were found to be more adherent to general diet, exercise activity and medication taking, respectively, compared to those with low efficacy to manage these domains.

Out of all interviewees, 87 (22.2%) achieved the target therapeutic goal and considered with controlled disease. Univariate analysis showed that the only predictor of diabetes control was diabetes management self-efficacy, as shown in Table 5. The 55 patients (28.8%) who had high self-efficacy, presented more frequently the disease controlled, compared to 32 (15.9%) with low self-efficacy, [OR 2.1 (1.3–3.5), p=0.002].

### RESULTS

The current study is the first one of its type to investigate the influence of self-efficacy management and its influence on adherence to self-care activities and disease control among diabetic Sudanese patients. Previous studies around the world demonstrated this association, but the documentation of this association at the level of Sudanese patients might convince healthcare authorities and institutions and adopt the concept in health education aiming to change patient behavior.

Analysis of the demographic variables of the patients recruited in this study showed that approximately 30% of them were living in rural areas, where it is difficult to reach the vital services. This reflects the centralization of health services for important chronic illness like diabetes. To the best of our knowledge, there are no specialized centers to provide care for diabetic patients in other states of Sudan. This might partially explain a late diagnosis, poor diseases control, and development of complications. More than half of the respondents had education between 0-9 years, which could affect the understanding of important health education messages. Unemployed participants represented 59%, which in agreement with Von Arx et al. study, where most of the population was unemployed because of diabetes complications. The major observed comorbid conditions were hypertension and dyslipidemia, which might increase the microvascular and macrovascular risk in patients with diabetes, but also might increase the financial burden, which inversely could affect the adherence to medication and self-care activities. In our study, nearly half (48.7%) of all interviewees participated in this study and were classified as having high self-efficacy among diabetic Sudanese patients. Previous studies around the world demonstrated this association, but the documentation of this association at the level of Sudanese patients might convince healthcare authorities and institutions and adopt the concept in health education aiming to change patient behavior.

### DISCUSSION

| Table 3. Mean number of days and adherence to diabetes self-care activities |
|-----------------------------------------------|
| **Diabetes self-care activities** | **Days/adherence. Mean (SD)** | **Adherent** |
| General diet | 5.1 (1.9) | 253 (64.5%) |
| Specific diet | 3.9 (1.9) | 121 (30.9%) |
| Physical exercise | 2.2 (2.3) | 69 (17.6%) |
| Medication taking | 6.1 (1.8) | 272 (69.4%) |
| Blood glucose testing | 1.7 (3.6) | 0 (0%) |
| Foot exams | 4.1 (3.0) | 0 (0%) |

| Table 4. Diabetes management self-efficacy and self-care management practice |
|-----------------------------------------------|
| **Domain** | **Self-efficacy** | **Adherent** | **p-value** |
| | **High** | **Low** | |
| Nutrition-general diet | 143 (76.1%) | 110 (53.9%) | 253 | <0.001 |
| Nutrition-specific diet | 64 (34.0%) | 57 (27.9%) | 121 | 0.150 |
| Physical exercise | 55 (27.6%) | 14 (7.3%) | 69 | <0.001 |
| Medication taking | 242 (74.2%) | 30 (45.5%) | 272 | <0.001 |
71.7% were classified as having a high level of self-efficacy to manage nutrition, physical exercise and weight control, and medical treatment, respectively. Comparatively, in a recent published study conducted among Saudi diabetic patients, self-efficacy was found to be moderately low.29 The most important predictors of high level of self-efficacy in our study were the participation in diabetic health education sessions and a high educational level (over 9 years). Both factors are deemed important for understanding all aspects related to the disease, complications, medical management and the importance of adherence to lifestyle recommendations. Diabetes management self-efficacy was reported as the single most important determinant of the disease control and influenced by educational status.29 Participation in diabetes education programs was also found to be a key factor in diabetes control.24 The results of our study identified the role of self-efficacy on adherence to diabetes self-care activities across important domains of lifestyle changes. This finding was in concordance with the results of other studies conducted in China25, India23, and Native Americans and Alaska Natives.29

Our results also showed that adherence to medication was higher compared to other self-care activities (diet and exercises). In another Sudanese study also conducted in Khartoum state, the authors quoted a deficiency in knowledge about the role of adherence to both domains in the control of the disease (diet 62.3% and physical exercise 51.2%).30 Only 22% of the respondents attained the target therapeutic goal for the control of diabetes. This high percentage of uncontrolled diabetes justifies the prevalence of disease complications observed among the interviewees. The only predictor of diabetes control was self-efficacy for the management of the disease. In fact, several studies had linked high self-efficacy with performing diabetes self-care behaviors, which directly linked to glycemic control.1,17,23,31 Self-efficacy is commonly presented as a contribute to the adjustment of the disease and good glycemic control in the long term.20 However, the literature is not be free from controversial results, with some authors supporting that adherence to self-care management behaviors are related to poor glycemic control9 and found no significant association between social support, self-efficacy, self-care behaviors and glycemic control.34 Overall, the findings of our study reflected the importance of self-efficacy as an important determinant of adherence to self-care activities and ultimately to glycemic control. Health care facilities caring for diabetic patients in Sudan should adopt educational intervention programs to increase the level of self-efficacy and to empower patients to better participate in the management of the disease. These goals could be achieved by incorporating self-efficacy in the ongoing education process and through social support.

**Limitations**

Our study presented some limitations. First, the study was conducted in two settings in one state, so the results cannot be generalized to all diabetic patients at the national level. Second, the study adopted convenience sampling. And third, the self-report method was used to collect data on adherence to self-care management activities, which imply the obtained results may suffer from any bias.

| Table 5. Determinants of diabetes control (univariate analysis) |

CONCLUSIONS

The level of self-efficacy and adherence to self-care management were high in about half of the respondents, and there was a significant association between self-efficacy and adherence to self-care activities and level of glycemic control. Educational level and formal diabetes education were found to be significantly associated with high level of diabetes management self-efficacy. Enhancing self-efficacy and adherence to self-care activities through continuous patient education must be taken in consideration in diabetes management plan.

ACKNOWLEDGEMENT

The authors would like to thank all staff members of Jabir Elizz Diabetes Centre and Soba Teaching Hospital for their unlimited help.

CONFLICT OF INTEREST

None to be declared.

FUNDING

None.
