LEPTON FLAVOR VIOLATION IN THE STANDARD MODEL
EXTENDED BY HEAVY SINGLET DIRAC NEUTRINOS

Abstract

Low energy neutrinoless lepton flavor violating (LFV) processes are studied
in an extension of the Standard Model (SM) by heavy $SU(2) \times U(1)$ singlet
Dirac neutrinos. An upper bound procedure is elaborated for the evaluation
of amplitudes. A comment on the extraction of heavy neutrino mixings from
astrophysical observations is given. For processes not treated in the applied
model the formalism for evaluating the branching ratios (BRs) is presented.
The processes previously studied in the model are carefully examined. Some
of the previous results are improved. Special attention is paid to the structure
of the amplitudes and BRs as well as to the relations between BRs of different
LFV processes. Numerical analysis of the BRs is done. The decoupling of
heavy neutrinos is discussed and it is explicitly shown that the very heavy
neutrinos decouple when the upper bound procedure is applied. The upper
limits of the BRs are compared with the current experimental upper bounds
and the processes interesting for the search for LFV are proposed. The LFV
decays are shown to be unsuitable for finding upper bounds on ”diagonal”
LFV parameters. The $B$-meson LFV processes are suggested for the search
of LFV in future $B$-factories.

I. INTRODUCTION

If the instanton effects [1] are neglected, lepton flavor and lepton number are conserved in the Standard Model (SM). Recently found atmospheric neutrino oscillations [2] indicate that neutrino masses are nondegenerate and the lepton flavor is not conserved. Independent confirmation of the deviation from SM is expected to manifest as a nonconservation of lepton flavor/number (LFV/LNV), as a breaking of lepton universality, in CP violating processes which are not consistent with SM etc.

The problem of LFV/LNV is related to the physics beyond SM and includes various physical areas [3]: atomic physics (e.g. muonium–antimuonium conversion), nuclear physics ($\mu \to e$ conversion, double beta decay), low energy hadron physics (leptonic and semileptonic decays of mesons and tau lepton), problem of CP violation etc.

LFV have been found in various extensions of SM [3–6]. Here, LFV is studied within one of two extensions of SM by heavy neutrinos [7,8], obtained by adding additional heavy Dirac neutrinos to it. It is referred here as the $V$ model [8]. Due to the Dirac character of the heavy neutrinos, there are no LNV processes in this model. The other model [7], obtained by extending SM with additional heavy Majorana neutrinos, has some renormalization problems and light neutrino mass problems [9]. Besides the additional heavy Dirac neutrinos, the $V$ model contains three massless neutrinos. It should be noted that in this work the $V$ model is used phenomenologically. Any model with the same gauge properties and about equally large heavy neutrino masses would give the same results, regardless whether the light neutrinos are massless or have masses which are in accord with the present experimental data.

The extensions of SM by heavy neutrinos contain a Cabibbo-Kobayashi-Maskawa type matrix for leptons (LCKM). In general, the elements of this matrix are not known. Experimental and theoretical constraints exist only for some specific sums of the matrix elements of the heavy neutrino part of the matrix. Therefore, the LFV amplitudes cannot be evaluated exactly, but only the upper bounds on their values may be found [10]. The evaluation is especially complicated when the amplitudes contain expressions with more than two LCKM matrix elements. In this paper a method for evaluation of the upper bounds of amplitudes found in the previous publication [10] is improved. The method gives upper bounds for all values of the model parameters, but in some directions of the parameter space it is not very restrictive. It is explicitly shown that the upper bound procedure leads to the decoupling of the heavy neutrinos in the infinite mass limit, showing that the "nondecoupling" of heavy neutrinos [1,2] is only a transient effect, appearing with enlargement of the heavy neutrino mass. It should be noted that this ”proof” of generalization of the Appelquist–Carrazone theorem is based only on the requirement that the physical system can be described perturbatively, and is independent of the introduction of somewhat undetermined maximal $SU(2)_L$-doublet mass term as in Ref. [2]. To give the feeling how large error can be introduced using the upper bound procedure elaborated here, a few branching ratios (BRs) obtained by the upper bound procedure are compared with BRs obtained using ”realistic” LCKM matrices.

The LFV processes are not very useful for deriving upper bounds on the matrix elements of LCKM matrix. The amplitudes for these processes are proportional to the sums of products of the LCKM matrix elements and functions of heavy neutrino masses. Using the freedom to choose unknown phases of the LCKM matrix and heavy neutrino masses,
these sums can always be set to be equal zero, even if the absolute values of nondiagonal elements of the LCKM matrix are different from zero. The present limits on the LCKM matrix elements are derived from the measurements of lepton flavor conserving processes \[13\], more precisely, from the estimates of deviations of the corresponding decay rates from the SM results. For each row (a row corresponds to a specific lepton \(l\)) of the LCKM matrix, these data give a limit on the sum of squares of absolute values of the matrix elements corresponding to the heavy neutrinos, \((s_{\nu l}^2)^2\). Knowing the upper bounds on \((s_{\nu l}^2)^2\)-s one may derive the upper bound for BR of any LFV process. One of the aims of this paper is to derive the upper bounds of BRs for all low energy LFV processes in the \(V\) model. The processes having comparable theoretical and experimental upper bounds of the BR, or theoretical upper bound larger than the experimental one, are interesting for further experimental investigation.

Neutrino oscillations of two massless neutrinos in supernovae have been shown to give a very strong upper bound of two of the LCKM matrix elements in the part of the matrix corresponding to the massless neutrinos \[14\]. Here, the analysis has been repeated for three neutrinos, hoping that the upper bounds for other ”massless neutrino” LCKM matrix elements may be derived. The knowledge of nondiagonal ”massless neutrino” LCKM matrix elements may, in principle, lead to better upper bounds on some combinations of ”heavy neutrino” LCKM matrix elements than the terrestrial experiments. Unfortunately, the analysis made here shows that the three-neutrino oscillations do not give new constraints on any combination of ”heavy neutrino” LCKM matrix elements. The only new information it gives is that the mixing between massless ”mu” and ”tau” neutrinos is smaller than the value obtained from the analysis of Super-Kamiokande data \[2\], in which ”mu” and ”tau” neutrinos were assumed to have small masses.

Until now, many of the low energy neutrinoless LFV processes have been investigated. Some of them were examined only within a few models, for instance LFV decays of heavy mesons. The neutrinoless LFV decays of B-mesons were studied in the frame of SM with additional Higgs doublet \[15\], while the neutrinoless LFV decays of D-mesons have been studied in the frame of leptoquark models \[16\] and a flipped left-right symmetric model \[17\]. Here, they are analyzed in the \(V\) model. Some of the low energy LFV processes have not been studied in the frame of the \(V\) model. Among them are the muonium–antimuonium \((M \leftrightarrow \bar{M})\) conversion and neutrinoless LFV violating decays of the \(Z\) boson. The results are also given here. Some of the neutrinoless LFV processes have been analyzed in the \(V\) model, but the analysis is incomplete \[18\] or there are some errors in the expressions for amplitudes or decay rates \[10–12\]. Here only the corrections to the previous results are given.

On the quark and lepton level there are only a few Feynman diagrams (composite loop functions) that contribute to any neutrinoless LFV decay amplitude. If two neutrinoless LFV processes contain only one common composite loop function, the ratio of corresponding BRs is independent of the \(V\)-model parameters. Therefore, roughly speaking, knowing one BR, BRs of processes comprising the same basic Feynman diagram may be evaluated without the knowledge of parameters of the \(V\) model. If LFV decay amplitudes contain different loop functions or more loop functions, the ratio of the BRs depends on \(V\)-model parameters. Nevertheless, the mass dependence of the ratio of the BRs simplifies in the limit of large heavy neutrino masses. Most of the amplitudes become dependent essentially only on one of the composite loop functions. In that limit, the ratios of the BRs having the same dominant
In the section II some properties of the V model, relevant for further discussion, are given. Discussion on the limits of the model parameters is given in the section III. The amplitudes for the neutrinoless LFV processes not studied in the V model, and some improvements and corrections of the previous results are presented in section IV. The amplitudes and BRs of LFV processes are studied in section V. The numerical results and comparison with experimental limits are also given in section V. Conclusions are summarized in section VI.

II. COMMENTS ON THE MODEL

Here, a model with additional $SU_L(2) \times U(1)$ singlet Dirac neutrinos, which have large mixings with the SM leptons, is used in the calculations. The masses of the singlet neutrinos are not restricted by the $SU_L(2) \times U(1)$ breaking scale. The large mixings and the large masses are necessary conditions for obtaining observable LFV decay rates.

In the model considered here [8,19–22], the total lepton number ($L$) is conserved. For each SM neutrino one left-handed and one right-handed singlet neutrino is added, although, in principle, the structure of the mass matrix permits addition of an arbitrary number of pairs ($n_{R}$) of left-handed and right-handed neutrinos ($Vn_{R}$ models). Lepton number conservation gives such a structure to the mass matrix which automatically leads to three massless neutrinos at any order of the perturbation theory [19].

Since the new neutrinos are $SU(2)_L \times U(1)$ singlets, the structure of the lepton interaction vertices in the weak basis is the same as in SM [19]. However, in a transition to the mass basis, nondegeneracy of the neutrinos leads to the Cabibbo-Kobayashi-Maskawa (CKM) type matrix ($B_{ln}$) in the charged current (CC) $nlW$ vertices. As only a part of the mass-basis neutrinos interact with the $Z$ boson, neutral current (NC) $nnZ$ vertices ($n$ is neutrino field in the mass basis) are also not flavor-diagonal, and contain matrix elements of the nondiagonal matrix ($C_{nn}$). The NC $llZ$ vertices and the quark vertices are the same as in SM.

The $C$ matrix from the neutrino NC vertex may be expressed in terms of $B$ matrices from the CC lepton vertex. Therefore, besides the SM parameters, the model depends only on the $B$ matrix (or more precisely on the parameters defining the $B$ matrix) and on heavy neutrino masses. The matrices $B$ and $C$ satisfy a set of relations stemming from the gauge structure (see e.g. [11]),

\[
\begin{align*}
\sum_{k=1}^{n_G+n_R} B_{1k}B_{2k}^* &= \delta_{11} \delta_{22}, \\
\sum_{k=1}^{n_G+n_R} C_{ik}C_{jk}^* &= C_{ij}, \\
\sum_{k=1}^{n_G+n_R} B_{ik}C_{ki} &= B_{ii}, \\
\sum_{l=1}^{n_G} B_{li}^*B_{lj} &= C_{ij}.
\end{align*}
\]

From the orthogonality relations for $B_{ln}$ matrix elements, phase arbitrariness of leptons and $SU(n_{R})$ invariance of massless neutrinos lead to $n_Gn_{R}$ independent angles and ($n_G - \ldots$)
1) \((n_R - 1)\) independent phases of the \(B\) matrix \([23, 24]\). Experimentally, only \(n_G\) parameters \(s_L^\nu\) may be estimated. Therefore, the \(B\) matrix elements are undetermined even for the simplest case with two additional heavy neutrinos, \(n_R = 2\). Since the \(B\) matrix elements are unknown, the amplitudes of LFV processes cannot be evaluated exactly, but only upper bounds of the amplitudes may be found. One should mention that there exists a model for which amplitudes of LFV processes can be evaluated exactly, in the case of \(n_R = 2\) \([7]\). Unfortunately, as mentioned before, it is excluded because of some renormalization and light-neutrino mass problems.

The degeneracy of massless neutrinos allows one to write the \(B\) matrix in the following form \([11, 19, 25]\)

\[
B_{lk} = [(UD_A)_{li}, (UG)_{Ni}], \quad k = (i, I),
\]

where \(U\) is a unitary matrix, \(D_A\) is a diagonal matrix and \(G\) is a matrix satisfying \(D_A^2 + GG^\dagger = 1\). Indices \(i\) and \(I\) denote massless and massive neutrinos, respectively. From the structure of the \(B\) matrix, it follows that the massless neutrino CC in principle is not diagonal, leading to LFV \([13, 23, 26]\) and nonorthogonal effective weak-neutrino states \([26]\), although neutrinos are massless. On the other side, the massless-neutrino NC, which contains the \(C\) matrix elements, is diagonal \([19]\). Since there are no tree-level flavor violating neutral currents (FCNCs) in the massless neutrino sector, the universality of massless neutrino couplings is not satisfied, because, in general, the elements of the diagonal matrix \(D_A\) are not equal. The nonuniversality of these couplings may have some astrophysical implications.

As mentioned in Introduction, the \(B\) matrices are used to define the parameters \(s_L^\nu\), which are a measure of the deviation from SM, in the following way \([12, 27 –30]\)

\[
(s_L^\nu)^2 = \sum_{i=1}^{n_R} B_{iN_i}B_{iN_i}^*. 
\]

Because the definition of \((s_L^\nu)^2\) contains \(B_{iN_i}\) matrix elements of the same lepton flavor, the term ”diagonal” mixing(s) will be sometimes used in the text below.

### III. LIMITS ON THE MODEL PARAMETERS AND METHODS OF EVALUATION OF AMPLITUDES

#### A. Experimental limits

The parameters \((s_L^\nu)^2\) have been determined from the global analysis of the low energy tree level processes \([13, 27, 30]\). In these processes heavy neutrinos may manifest only indirectly, through change of the light (massless)-neutrino couplings. These couplings attain additional \(c_L^\nu\) factors, where \((c_L^\nu)^2 \equiv 1 – (s_L^\nu)^2 = \sum_{i=1}^{n_G} B_{i\nu_i}B_{i\nu_i}^*\). The changes of the couplings could show up as a nonuniversality of CC couplings, as a deviation from unitarity of the CKM matrix, as a change of the invisible width of the \(Z\) boson etc. \([3, 28]\). The best limits on the mixings \(s_L^\nu\),

\[
(s_L^\nu)^2 < 0.0071, \quad (s_L^\nu)^2 < 0.0014, \quad (s_L^\nu)^2 < 0.033(0.01),
\]
were found in Ref. [13]. The value in the brackets is valid for $SU(2)_L \times U(1)$ singlet heavy neutrinos.

The more stringent limits on the $B_{IN}$ matrix elements were searched for investigating the loop effects in the lepton-conserving and lepton-violating processes. Direct limits on the parameters $s^\nu_L$ are not possible as the expressions derived from the loop amplitudes, which are constrained by experimental data, depend not only on the $s^\nu_L$ parameters but also on the $B_{IN}$ phases and masses of heavy neutrinos. Lepton conserving processes including heavy neutrinos in loops were studied by Kalyniak and Melo [31,32]. They studied the loop effects of heavy Dirac neutrinos on muon decay, universality-breaking ratio in $Z \to \ell\ell$ decays and $\Delta r$ quantity. They found no new constraints on the $s^\nu_L$ parameters. The flavor nondiagonal (LFV) processes without light neutrinos in the final state were studied extensively both theoretically [3,4,19,23,35] and experimentally [3,34–37]. The advantage of these processes is that their observation would be a clear and unambiguous signal for LFV. These processes proceed only through loops. Using independence of the loop functions on the light neutrino masses and the orthogonality of rows of $B$ matrix, the amplitudes of these processes may always be expressed in terms of heavy neutrino contributions only. Three of these processes, $\mu \to e\gamma$, $\mu \to 3e$ and $e-\mu$ conversion in $Ti$, gave new very stringent constraints on a specific combinations of heavy neutrino masses and matrix elements $B eN$ and $B_{\mu N}$ [12]. Particularly, near-independence of the $\mu \to e\gamma$ amplitude on heavy neutrino masses enables one to find the following very stringent mass independent limit,

$$\sum_{i=1}^{n_R} B^*_{\mu N_i} B_{eN_i} < 2.4 \times 10^{-4}. \quad (5)$$

No other constraints independent of heavy neutrino masses were derived from the LFV processes. It should be noted that the limit (5) does not necessarily lead to new limits on the $s^\nu_L$ parameters. The sum in (4) may be written in terms of the parameters $s^\nu_L$ and $s^{\nu e}_L$ and a complex ”cosine” of the ”angle” between vectors $\{B_{\mu N_i}\}$ and $\{B_{eN_i}\}$,

$$\sum_{i=1}^{n_R} B^*_{\mu N_i} B_{eN_i} = s^\nu_L s^{\nu e}_L \cdot x^0_{\mu e}, \quad (6)$$

where $x^0_{\mu e} = \sum_{i=1}^{n_R} B^*_{\mu N_i} B_{eN_i}/s^\nu_L s^{\nu e}_L$. Obviously a reduction of $x^0_{\mu e}$ may assure the fulfillment of the inequality (3) without reducing the $s^\nu_L$ parameters. Within the $V$ model the explicit estimates of BRs for the processes including more than two $B_{IN}$ matrices were given for the first time in Ref. [10].

**B. A comment on astrophysical limits**

The masslessness of ”light” neutrinos in the $V$ model lead to the limits on some $B_{\nu\nu}$ matrix elements which can be derived from astrophysical observations. Valle and collaborators have noticed that the measurements of neutrino flux from the supernova SN87 leads to two very small lepton–massless-neutrino mixings [14],

$$|B_{e\nu_e}|, |B_{\tau\nu_e}| < 10^{-3}. \quad (7)$$
The result (7) follows from an estimate of the $\nu_e - \nu_\tau$ conversion probability in the V model. To find whether similar upper bounds can be found for other massless-neutrino $B$ matrix elements, their calculation is repeated here for three massless neutrinos. The motivation for such calculation is following. Through the orthogonality relations for $B$ matrix elements, very stringent limits on the matrix elements $B_{lN}$ would lead to better upper bounds on nondiagonal mixings $\sum_{i=1}^{nR} B_{lN_i} B_{l'N_i}^*$ than those obtained by terrestrial experiments.

The derivation of the limits (7) is based on an analysis of neutrino oscillations of the two neutrinos for which the experimental upper bounds on $s_{\nu_l L}$ parameters are the weakest – $s_{\nu_e L}$ and $s_{\nu_\tau L}$. The oscillations of massless neutrinos are a consequence of an interplay between the CC and NC neutrino weak interactions [38]. They appear only if the universality of the NC interactions is not fullfilled and if the nondiagonal CC currents are different from zero. Following the notation of Refs. [14,38], the deviation from the universality is described by small parameters $h_l$ (for small $h_l$, $h_l \approx s_{\nu_l L}$). The massless-neutrino part of the $B$ matrix is parametrized by one mixing angle $\theta$, which is assumed to be small. The resonance condition reads

$$2Y_e = \frac{h_\tau^2 - h_e^2}{1 + h_e^2},$$  \hspace{1cm} (8)$$

where $Y_e = n_e/(n_e + n_n)$, $Y_n = 1 - Y_e$ and $n_e$ and $n_n$ are the electron and the neutron number densities. As the experimental limits on $h_e$ and $h_\tau$ are much smaller than one, the resonance condition can be fullfilled only in a highly neutronized medium, which can be found in supernovae explosions. In Ref. [14] it was shown that the neutrinosphere appears for the electron fraction $Y_e \approx 6 \times 10^{-3}$. The experimental upper bounds [4] show that the resonance condition can be fullfilled for $Y_e \lesssim 0.015$, quite close to the $Y_e$ value at the neutrinosphere. Assuming there is no nonforward scattering of neutrinos [39], the authors of Ref. [14] found the probability for $\nu_e \leftrightarrow \nu_\tau$ and $\bar{\nu}_e \leftrightarrow \bar{\nu}_\tau$ conversions in a simple Landau-Zener approximation [40,41],

$$P \equiv P(\bar{\nu}_e \rightarrow \bar{\nu}_\tau) = 1 - P(\nu_e \rightarrow \bar{\nu}_e) = \frac{1}{2} - \left[ \frac{1}{2} - \exp \left(-\frac{\pi^2}{2} \frac{\delta r}{L_{res}} \right) \right] \cos 2\theta \cos 2\theta_m \approx 1 - \exp \left(-\frac{\pi^2}{2} \frac{\delta r}{L_{res}} \right) \equiv 1 - P_{LZ},$$  \hspace{1cm} (9)$$

where $P_{LZ}$ is the Landau-Zener crossing probability, $L_{res}^{res}$ is the neutrino oscillation length in matter at resonance, $\theta_m \approx \pi/2$ is the mixing angle in matter at production point (neutrinosphere) and $\delta r = 2 \sin 2\theta |d \ln Y_e/dr|^{-1}_{res}$. The approximate equality in (9) is a consequence of the small mixing angle ($\theta$) approximation. Using that result, the expression for the detected terrestrial flux [42],

$$\phi_{\bar{\nu}_e} = \phi_{\nu_e}^0 (1 - P) + \phi_{\nu_e}^0 P$$  \hspace{1cm} (10)$$

($\phi_{\nu_e}^0$ and $\phi_{\bar{\nu}_e}^0$ are $\nu_e$ and $\bar{\nu}_e$ fluxes in the absence of the neutrino conversion, respectively), the model independent result for the probability for $\nu_e \leftrightarrow \nu_\tau$ conversion, $P < 0.35$ [42], and the density profiles for $Y_e$ from the Wilson supernova model, Valle and his collaborators found the result given in Eq. (7).
Following the procedure of Ref. [14], a similar analysis can be done for the three massless neutrinos. To analyze the terrestrial flux data, one should know only the survival probability of the electron antineutrino \( P(\bar{\nu}_e \rightarrow \bar{\nu}_e) \) [41,43]. The Eq. (10) is still valid, but the \( \phi^0_{\bar{\nu}_e} \) represents the sum of the \( \bar{\nu}_\mu \) and \( \bar{\nu}_\tau \) fluxes. In the three-neutrino case there are two resonances: \( \bar{\nu}_e \leftrightarrow \bar{\nu}_\mu \) resonance and \( \bar{\nu}_e \leftrightarrow \bar{\nu}_\tau \) resonance. According to the limits (4) and the \( Y_e \) value at the neutrinosphere, the \( \bar{\nu}_e \leftrightarrow \bar{\nu}_\mu \) resonance is within the neutrinosphere. Therefore, the effects of this resonance do not contribute to \( P(\bar{\nu}_e \rightarrow \bar{\nu}_e) \). Taking that into account (or equivalently taking the neutrinosphere as a source of neutrinos) and using the approximative Kuo–Pantaleone treatment for three neutrino oscillations [41] adjusted for physical situation studied here, one obtains the following expression for \( P \equiv 1 - P(\bar{\nu}_e \rightarrow \bar{\nu}_e) \):

\[
P = 1 - \left( |U_{e1}|^2 P_{LZ} + (1 - P_{LZ}) |U_{e2}|^2 \right) \left( |U_{e1}|^2 + |U_{e2}|^2 \right) - |U_{e3}|^4 \]

\[
= 1 - P_{LZ} \cos^4 \phi \cos 2\omega - \cos^4 \phi \sin^2 2\omega - \sin^4 \omega
\]

(11)

(neutrino states 1, 2 and 3 are mainly \( \nu_e, \nu_\tau \) and \( \nu_\mu \) flavor states, respectively; the angles \( \omega \) and \( \phi \) perform rotations between 1 and 2 states, and 2 and 3 states, respectively). The Landau-Zener crossing probability \( P_{LZ} \) can be obtained from the \( P_{LZ} \) for two-neutrino oscillations, replacing \( \sin 2\theta \) with \( 2U_{e1}U_{e2} = \cos^2 \phi \sin 2\omega \) in the two-neutrino \( P_{LZ} \). In the small angle approximation, assumed in Ref. [14], the probability \( P \) tends to zero only if \( P_{LZ} \) is almost equal one. Using the result of Ref. [42] mentioned above, \( P < 0.35 \), the small angle approximation, and the analysis of Ref. [14], one finds limits on mixing angles \( \omega \) and \( \phi \):

\[
\sin^2 2\omega < 1 \times 10^{-6}, \quad \phi^2 < 0.27.
\]

(12)

The first limit corresponds to the limit obtained in the two neutrino case. The second one is too weak to give limits on the \( B_{\ln} \) matrix elements. Therefore, astrophysical measurements give no new limits on the heavy neutrino part of the \( B \) matrix.

The second limit has to be compared with the \( \nu_\mu - \nu_\tau \) mixing angle obtained from the favorite interpretation of recent Super-Kamiokande results [2], \( \theta_{\nu_\mu, \nu_\tau} \approx \pi/4 \). Obviously, these two results are in a slight contradiction.

C. Theoretical limits

If one wants to work in the perturbative regime of the theory, an additional constraint on the \( B_{\ln} \) mixings comes from the theoretical argument that the partial wave unitarity (perturbative unitarity) has to be satisfied. From the perturbative unitarity follows that the decay width of any heavy neutrino has to be smaller than a half of its mass. Written in terms of heavy neutrino masses and \( B_{\ln} \)-s, this condition reads [10]

\[
m^2_{N_i} \sum_{j=1}^{n_0} |B_{ljN_i}|^2 \leq \frac{4}{\alpha_W} M^2_W \equiv m^2_D.
\]

(13)

\( m_D \) represents the upper value the Dirac mass may attain in the neutrino mass matrix. The perturbative unitarity bound (PUB) inequalities (13) give upper limit on a combination of a heavy neutrino mass \( m_{N_i} \) and the matrix elements \( B_{ljN_i} \). Using Eq. (1), these relations may be combined into the limit for the lightest heavy neutrino mass

8
\[ m_{N_i}^2 \leq (m_{N_i}^0)^2 (1 + \frac{n_R}{m_{N_i}}), \]  \hspace{1cm} (14)

where \((m_{N_i}^0)^2 = 4M_W^2/\alpha_W \sum_{j=1}^{n_R} (s_{L_j}^\mu)^2\) and \(\rho_i = m_{N_i}/m_{N_1}\). Concerning the calculation of BRs, the bound is very effective if the heavy neutrino masses are equal. If the heavy neutrino masses differ considerably, the bound is not very restrictive. Namely, if one of the heavy neutrino masses is smaller than \(m_{N_1}/n_{R_1}^{1/2}\), the others may acquire infinite values not followed by infinitely small values of the corresponding \(B_{lN_i}\) mixings. That leads to divergent BRs. Therefore, one has to use the original inequality (13) to restrict model parameters. One cannot obtain closed expressions since the model has too many free parameters, but one can write two very rough bounds \[ |B_{lN_i}| \leq s_{L_i}^\mu, \]
\[ |B_{lN_i}| \leq \frac{2M_W}{\alpha_W^{1/2} m_{N_i}} \equiv B_{lN_i}^{(0)}. \]  \hspace{1cm} (15)

originating from Eqs. (3) and (13), respectively, which have to be satisfied simultaneously. If the heavy neutrino masses differ considerably, the bounds (15) are better for finding upper bounds of BRs than the bound (14).

The "realistic" \(B_{lN_i}\)-s which automatically satisfy the PUB-s (15) and fullfill the relation \(\sum_i B_{lN_i} B_{lN_i}^* \leq (s_{L_i}^\mu)^2\) may be obtained by putting
\[ B_{lN_i} = ((s_{L_i}^\mu)^{-1} + (B_{lN_i}^{(0)})^{-1})^{-1} n_{R_i}^{-1/2}. \]  \hspace{1cm} (16)

This choice of \(B_{lN_i}\)-s is used below to give an estimate how large error can be done in the evaluation of BRs using the rough upper bound procedure presented above. The \(B_{lN_i}\) defined in Eq. (16) begins to differ considerably from the value \(s_{L_i}^\mu\) for \(m_{N_i} \gtrsim 100M_W(0.1/s_{L_i}^\mu)\). Therefore, for \(m_{N_i}\) values smaller than 2000 GeV, the \(B_{lN_i}\)-s are determined by experimental upper bounds \[\] and not by the theoretical PUB limits \(B_{lN_i}^{(0)}\).

D. Upper bound procedure for LFV amplitudes

The equations (15) and (16) are the basis for evaluation of the LFV amplitudes. The evaluation based on Eq. (15) gives the upper bounds on absolute values of the amplitudes \[\], which have to be satisfied by any model with additional heavy neutrinos. It uses the Schwartz’s inequality for the product of two vectors. It always gives larger estimates for an amplitude than the approach based on Eq. (16). In both approaches the phases of the \(B_{lN_i}\)-s are neglected, but in a different manner. In the first approach the upper bound value of the amplitude is formed, while in the second the \(B_{lN_i}\)-s are taken to be real and positive. Both approaches explicitly show that the very heavy neutrinos are decoupled. That is, they have no influence on the amplitudes of low energy LFV processes, in accord with the Appelquist-Carazzone theorem and its generalization \[\] and its generalization \[\].

Here, the improved version of the upper bound procedure introduced in Ref. \[\] is given. The low energy LFV amplitudes may be written in terms of
Finally, the numerical values of the
where dots represent the indices not written explicitly. Namely, the amplitudes often contain more than one sum over neutrino or quark flavors. Using the inequalities that can be derived from Schwartz’s inequality,

\[
| \sum_{i} a_{i} b_{i} c_{i} | \leq \sum_{i} |a_{i}||b_{i}||c_{i}|, \tag{18}
\]

\[
| \sum_{i} a_{i} b_{i} c_{i} | \leq |a||b|\langle c \rangle + |a||b|(\sum_{i=1}^{n} |c_{i} - \langle c \rangle|^{2})^{1/2}, \tag{19}
\]

\[\langle c \rangle = \frac{\sum_{i=1}^{n} c_{i}/n} {n}\]

and definition of \(s_{\nu}^{R}\) (3), one can write the following upper limits for the expressions (17),

\[
\left| \sum_{i=1}^{n_{R}} B_{iN_{i}}^{*} B_{iN_{i}} f(N_{i}, \cdots) \right| \leq s_{\nu}^{R} s_{\bar{L}}^{R} |f(\cdots)\rangle_{N} + \sum_{i=1}^{n_{R}} |f(N_{i}, \cdots) - \langle f(\cdots) \rangle_{N}|^{2} \right)^{1/2}, \tag{20}
\]

\[
\left| \sum_{j=1}^{n_{R}} V_{u_{j}d_{j}} V_{u_{j}d_{j}}^{*} f(u_{j}, \cdots) \right| \leq \sum_{j=1}^{n_{R}} |V_{u_{j}d_{j}}||V_{u_{j}d_{j}}||f(u_{j}, \cdots)|, \tag{21}
\]

\[
\left| \sum_{j=1}^{n_{R}} V_{ud_{j}} V_{ud_{j}}^{*} f(d_{j}, \cdots) \right| \leq \sum_{j=1}^{n_{R}} |V_{ud_{j}}||V_{ud_{j}}||f(d_{j}, \cdots)|, \tag{21}
\]

where \(\langle \cdots \rangle_{N}\) represents the average over heavy neutrinos. The inequality (18) gives the best estimate for the upper limit if the components \(c_{i}\) differ considerably. The inequality (19) gives the better estimate of the upper bound if the components \(c_{i}\) are approximately equal. As the amplitudes \(f(u_{j}, \cdots)\) and \(f(d_{j}, \cdots)\) depend strongly on quark masses, Eqs. (21) give good estimates for the upper bounds. Eq. (20) is effective if the heavy neutrino masses are nearly degenerate, because most of the \(f(N_{i}, \cdots)\) functions depend strongly on the heavy neutrino masses. If one or more heavy neutrino masses differ considerably from the others, then Eq. (20) may lead even to a divergent result as the heavy neutrino mass(es) tend to infinity. To avoid such undesirable behavior, one has to use the combination of the upper bounds (18) and (19) for each set of heavy neutrino mass values in the following manner. First, the heavy neutrino masses are arranged in increasing order. The arranged masses are divided into two sets, one containing smaller masses and the other larger masses. There are \(J + 1\) such partitions, where \(J\) is a number of different heavy neutrino masses. Then \(J + 1\) different upper bounds of the expression \(\sum_{i=1}^{n_{R}} B_{iN_{i}}^{*} B_{iN_{i}} f(N_{i}, \cdots)\) are formed combining the upper bounds (18) and (19),

\[
\left| \sum_{i=1}^{n_{R}} B_{iN_{i}}^{*} B_{iN_{i}} f(N_{i}, \cdots) \right| \leq s_{\nu}^{R} s_{\bar{L}}^{R} |f(\cdots)\rangle_{s} + \sum_{i_{s}} |f(N_{i_{s}}, \cdots) - \langle f(\cdots) \rangle_{s}|^{2} \right)^{1/2} \]

\[+ \sum_{i_{b}} B_{iN_{i_{b}}}^{0} B_{iN_{i_{b}}}^{0} |f(N_{i_{b}}, \cdots)|, \tag{22}\]

where \(\sum_{i_{s}}\) sums over the lighter heavy neutrino masses, and \(\sum_{i_{b}}\) over the heavier ones. Finally, the numerical values of the \(J + 1\) upper bounds (22) are compared and the smallest
of them is taken to be the upper bound value. For amplitudes containing sums over two (heavy neutrino and/or quark) indices, the procedure is essentially the same. Again one looks for the minimal upper bound value between upper bounds obtained for all possible partitions of heavy neutrino masses. This procedure gives convergent results for absolute values of the amplitudes, and it leads to the decoupling of the very heavy neutrinos.

It should be noted that the above upper bound procedure gives upper bounds for BRs for neutrinoless LFV processes. Recently, lower bound limits for \( \tau \) lepton decays were found using the Super-Kamiokande data on atmospheric deficit of \( \nu_\mu \), and interpreting it in terms of the best fit to these data [10]. The mild GIM mechanism suppression, coming from logarithmic dependence on light neutrino masses, appearing in \( \tau \rightarrow \mu l^+ l^-/\mu \rho^0 \) decays, leads to the lower bounds of the BRs as large as \( \sim 10^{-14} \). As the experimental upper limits on these processes are of the order of \( \sim 10^{-6} \) this lower limit is very welcome, because it strongly restricts the window for the heavy neutrino LFV effects. However, these results have to be taken with caution, as the standard interpretation of the Super-Kamiokande data is not the only one [47], although recent papers [48,49] showed that the energy dependence of the oscillation wavelength strongly supports the standard interpretation. It should be noted that the used \( V \) model can easily be modified to include masses for massless neutrinos [20]. The results for the neutrinoless LFV decays almost do not change if light neutrino masses, consistent with Super-Kamiokande measurements, are introduced.

**IV. NEW RESULTS ON LOW-ENERGY NEUTRINOLESS LFV PROCESSES**

As mentioned in Introduction, heavy meson neutrinoless LFV decays and \( M \leftrightarrow \bar{M} \) conversion have not been studied in the \( V \) model. They are examined below. Some previous results for neutrinoless LFV decays are extended and/or corrected.

**A. Neutrinoless LFV decays of heavy mesons**

The LFV decays of heavy mesons were discussed in a few papers in the context of the leptoquark models [16], a flipped left-right symmetric model [17] and SM with an additional Higgs doublet [15]. In these decays both lepton and quark flavor are changed. In the \( V \) model they can proceed only through box diagrams in which two \( W \) bosons are exchanged. The effective Lagrangian on the quark-lepton level reads

\[
\mathcal{L}_{\text{eff}} = \frac{\alpha_W^2}{16M_W^2} \sum_{l \neq l'} \sum_{Q} \sum_{q_a} F_{\text{box}}^{ll'q_aQ} \bar{l} \gamma_\mu (1 - \gamma_5) l' \bar{q}_a \gamma^\mu (1 - \gamma_5) Q \left[ \delta_{Qe} \delta_{q_au} - \delta_{Qb} (\delta_{q_ad} + \delta_{q_as}) \right].
\]

(23)

\( l \) and \( l' \) are the lepton fields, \( q_a \) and \( Q \) are the light and heavy quark fields, respectively, \( \alpha_W \) is the weak fine-structure constant, \( M_W \) is the \( W \) boson mass and \( F_{\text{box}}^{ll'q_aQ} \) is the composite loop function,

\[
F_{\text{box}}^{ll'q_aQ} = \sum_{i=1}^{n_R} \sum_{j=1}^{n_G} B_{iN_i}^* B_{iN_i} V_{u_d}^* V_{c_d} \left[ H_{\text{box}}(\lambda_{N_i}, \lambda_{d_j}) \right]
\]
\[ -H_{\text{box}}(\lambda_{N_i}, 0) - H_{\text{box}}(0, \lambda_{d_j}) + H_{\text{box}}(0, 0) \],
\[ F_{\text{box}}^{q'q_{ab}} = \sum_{i=1}^{n_R} \sum_{j=1}^{n_G} B_{iN_i}^* B_{jN_j} V_{u_i d_a} V_{u_j b} [F_{\text{box}}(\lambda_{N_i}, \lambda_{d_j}) - F_{\text{box}}(\lambda_{N_i}, 0) - F_{\text{box}}(0, \lambda_{d_j}) + F_{\text{box}}(0, 0)]. \]  

\[ (24) \]

\( F_{\text{box}} \) and \( H_{\text{box}} \) are loop functions defined in [40]. These loop functions have approximately logarithmic dependence on the heavy neutrino masses.

The dominant processes are those which have maximal value of the CKM matrix elements, maximal LCKM matrix elements and \( t \)-quark mass in the loop function. The main neutrinoless LFV candidates, between the two-prong and three-prong processes studied here, are \( \bar{B}^0_s \to \tau^\pm e^\mp, B^- \to K^- \tau^\pm e^\mp, \bar{B}^0 \to \bar{K}^0 \tau^\pm e^\mp \) and \( \bar{B}^0_s \to \phi \tau^\pm e^\mp \). There are no interesting \( D \) meson candidates for two reasons: one is of dynamical origin – the quark masses involved in loop functions are smaller than in \( B \)-meson decays, so loop functions are much smaller. The only larger loop contribution coming from the b-quark is suppressed by small CKM matrix elements. The other is kinematical – the difference of \( \tau \) lepton and \( D \) meson masses is small. The small quark masses in loops and large \( t \)-quark width makes LFV decays of \( t \)-quark uninteresting from the experimental point of view.

The matrix element of the neutrinoless LFV decay of a heavy meson \( H, H \to Xl\ell' \), contains hadronic matrix element \( \langle X|\bar{q}_a(0)\gamma^\mu(1 - \gamma_5)Q(0)|H \rangle \). The corresponding matrix elements are usually parametrized in the following way [51,52].

\[ \langle 0|\bar{q}_a(0)\gamma_\mu(1 - \gamma_5)Q(0)|H(p) \rangle = -if_{H \mu}, \]
\[ \langle P(p')|\bar{q}_a(0)\gamma_\mu(1 - \gamma_5)Q(0)|H(p) \rangle = \left[ \left( (p + p')_\mu - \frac{m_H^2 - m_{P'}^2}{q^2} q_\mu \right) F_1(q^2) + \frac{m_H^2 - m_{P'}^2}{q^2} q_\mu F_0(q^2) \right] N_\mu^a, \]
\[ \langle V(p', \varepsilon)|\bar{q}_a(0)\gamma^\mu(1 - \gamma_5)Q(0)|H(p) \rangle = \left[ -\frac{2V(q^2)}{m_H + m_V} \varepsilon^{\mu\nu\alpha\beta} \varepsilon_{\nu}^* P_\alpha P_\beta' - i\varepsilon^* \cdot q \frac{2m_V}{q^2} q_\mu A_0(q^2) \right. \]
\[ - \left. \frac{i\varepsilon^* \cdot q}{m_H + m_V} \left( (p + p')_\mu - \frac{m_H^2 - m_V^2}{q^2} q_\mu \right) A_2(q^2) + i(m_H + m_V) \left( \varepsilon_{\mu}^* - \frac{\varepsilon^* \cdot q}{q^2} q_\mu \right) A_1(q^2) \right] N_\varepsilon^a. \]

\[ (25) \]

\( H_a \) is a heavy pseudoscalar meson containing light quark \( \bar{q}_a \), \( P \) and \( V \) are a light pseudoscalar meson and a light vector meson, respectively, \( p \) and \( p' \) are 4-momenta of the heavy and light meson, respectively, \( q = p - p' \) is the momentum transfer, \( \varepsilon \) is the polarizaton vector of the light vector meson, \( f_H \) is the decay constant of the heavy pseudoscalar meson, \( F_1, F_2, V, A_0, A_1 \) and \( A_2 \) are form factors and \( N_{\mu}^a (N_\varepsilon^a) \) is a factor in front of the term containing \( \bar{q}_a \) in the quark wave function of the \( P (V) \) meson. The \( q^2 \) dependence of the form factors is a consequence of long-distance (resonance) effects following from strong interactions.

To evaluate the hadronic matrix elements of quark currents and to include the long distance effects, one has to express the quark currents in terms of the meson states and to introduce a strong-interaction Lagrangian on the meson level. Similar hadronic matrix elements have been extensively studied in radiative, semileptonic and nonleptonic decays of
The form factors of light mesons. The combination of heavy quark effective theory (HQET) and chiral perturbation theory (CHPT) has been applied to these decays. Here, the modification of this formalism is used. The authors of these papers replaced the HQET propagators by the full heavy-quark propagators, and introduced SU(3) symmetry breaking through physical masses and decay constants of light mesons. The matrix elements in that approach read

\[
\langle 0| \bar{q}_a(0)\gamma_{\mu}(1 - \gamma_5)Q(0)|H(p)\rangle = -if_H p_{\mu},
\]

\[
\langle P(p')| \bar{q}_a(0)\gamma_{\mu}(1 - \gamma_5)Q(0)|H(p)\rangle = N_V \left[ -f_H p_{\mu} + 2f_{H^*} (m_{H}m_{H^*})^{1/2} \right]
\times g \left( \frac{p_{\mu} - p'_{\mu} q_{\mu}}{m_{H^*}^2 - m_{H^*}^2} \right),
\]

\[
\langle V(p', \varepsilon)| \bar{q}_a(0)\gamma_{\mu}(1 - \gamma_5)Q(0)|H(p)\rangle = N_V \left[ 2^{3/2} \lambda g_V \left( \frac{m_{H^*}}{m_{H}} \right)^{1/2} f_{H^*} \frac{m_{H^*}}{q^2 - m_{H^*}^2} \varepsilon_{\mu\nu\alpha\beta} \varepsilon^{\nu\pi} p^\alpha \varepsilon^\beta \right]
\times \left[ \varepsilon_{\mu} - \frac{m_H^2}{2m_{H^*}^2} \varepsilon_{\mu} + i \frac{1}{2} \alpha_1 g_V m_{H^*} \varepsilon^{\mu} \right] + \frac{i}{2} \alpha_2 g_V m_{H^*} \varepsilon^{\mu} \frac{1}{2} p_{\mu} \varepsilon^* \frac{m_H^2}{2m_{H^*}^2} \right].
\]

(26)

\( H' \) and \( H^* \) represent heavy pseudoscalar meson and heavy vector meson resonances, respectively, \( f_H, f_{H^*}, m_H, m_{H^*} \) are the corresponding decay constants and masses, \( g_V \approx 6.0(2/a)^{1/2} \) with \( a = 2 \) in the case of exact vector meson dominance) is the vector meson self-interaction coupling constant. \( g, \beta, \lambda \) are the coupling constants in the even part of the strong interaction Lagrangian, \( \alpha_1, \alpha_2 \) are coupling constants in the odd part of the strong interaction Lagrangian, and \( \alpha_1 \) and \( \alpha_2 \) are free parameters which have to be determined from experimental data.

The matrix elements of \( H \rightarrow Xll' \) follow from (23), (24) and (26). From these matrix elements follow the corresponding decay rates:

\[
B(H_0 \rightarrow l^- l'^+) = \frac{\alpha_V^4 f_H^2 m_{H_0}^2 \lambda_{l^2}^2 (m_{H_0}^2, m_{l}^2, m_{l'}^2) m_{H_0}^2 (m_{l}^2 + m_{l'}^2) \Gamma_{H_0}^2}{2^{10} \pi \Gamma_{H_0}^2 M_W^4} |F_{box}^{l' l_0} Q|^2,
\]

\[
B(H_a \rightarrow p l^- l'^+) = \frac{\alpha_V^4 (N_{H_a}^2)^2 \Gamma_{H_0}^2}{2^{13} \pi^3} \int (m_{H_0}^2 - m_{l}^2)^2 dt \left[ a_P Z_{P1} + a_P b_P Z_{P2} + b_P Z_{P3} \right] |F_{box}^{l' l_0} Q|^2,
\]

\[
B(H_a \rightarrow V l^- l'^+) = \frac{\alpha_V^4 (N_{H_a}^2)^2 |F_{box}^{l' l_0} Q|^2}{2^{12} \pi^3} \int (m_{H_0}^2 - m_{l}^2)^2 dt \left[ a_V^2 Z_{V1} + b_V^2 Z_{V2} + c_V^2 Z_{V3} + d_V^2 Z_{V4} + a_V c_V Z_{V5} + b_V c_V Z_{V6} + b_V d_V Z_{V7} + c_V d_V Z_{V8} \right].
\]

(27)

The form factors \( a_P, b_P, a_V, b_V, c_V \) and \( d_V \), and phase functions \( Z_{Pi}, i = 1, 2, 3 \) and \( Z_{Vi} \) are defined in Appendix.

### B. Muonium–antimuonium conversion

The CC vertices in the \( V \) model have \( V - A \) structure. The effective Lagrangian for the \( M \leftrightarrow \bar{M} \) conversion comes from the lepton box amplitude. Therefore, the structure of the
effective Hamiltonian density for \( M \leftrightarrow \bar{M} \) has the same \((V-A) \times (V-A)\) form as in the
Feinberg’s and Weinberg’s papers \[60\]
\[
\mathcal{H} = G_{M\bar{M}} \bar{\psi}_\mu \gamma_\lambda (1 - \gamma_5) \psi_e \bar{\psi}_\mu \gamma_\lambda (1 - \gamma_5) \psi_e,
\] (28)
in which they had elaborated the original idea of Pontecorvo \[61\]. The constant \( G_{M\bar{M}} \) contains information on physics beyond SM. In the frame of the \( V \) model it comprises the parameters of the box amplitude for the process \( \mu^+e^- \rightarrow \mu^-e^+ \), which is forbidden in SM,
\[
G_{M\bar{M}} = \frac{\alpha_W^2}{16M_W^2} F_{\text{box}}^{\mu\mu}. \quad (29)
\]
\( F_{\text{box}}^{\mu\mu} \) is a composite loop function having the following structure \[11\]
\[
F_{\text{box}}^{\mu\mu} = 2 \sum_{ij=1}^{n_R} B_{eN_i} B_{eN_j} B_{\mu N_i}^* B_{\mu N_j}^* [F_{\text{box}}(\lambda_{N_i}, \lambda_{N_j}) - F_{\text{box}}(0, \lambda_{N_j}) - F_{\text{box}}(\lambda_{N_i}, 0) + F_{\text{box}}(0, 0)].
\] (30)
Using the expression (30) for large degenerate heavy neutrino masses, one obtains the limit
\[
G_{M\bar{M}} \leq 3.9 \times 10^{-5} x_{\mu\mu}^0 G_F. \quad (31)
\]
where \( G_F \) is the Fermi constant and \( x_{\mu\mu}^0 = F_{\text{box}}^{\mu\mu} / (0.5 \lambda_N (s_{\mu e}^L)^2 (s_{\mu e}^R)^2). \) From the definition of the composite loop function and the limit (3) follows that the \( x_{\mu\mu}^0 \) may assume only values smaller than \( 4.7 \times 10^{-3} \). Keeping that in mind, the result (31) has to be compared with the recent experimental upper bound \[37,38\] which improved the previous experimental result \[63\] by the factor \( \sim 50 \), \( G_{M\bar{M}} \leq 3.0 \times 10^{-3} G_F. \) The upper bound (31) is larger than the result found by Swartz \[64\], estimated within SM with massive Dirac neutrinos, by comparing the effective Hamiltonians for \( M-\bar{M} \) conversion and for \( B^0-\bar{B}^0 \) transition. Having in mind that the upper limit (3) was much weaker than when Swartz wrote his paper, the result obtained here is in fact larger than the numerical results show. The \( G_{M\bar{M}} \) was also evaluated in many other models \[63\]. Depending upon the variant of the model, the value of \( G_{M\bar{M}} \) ranges from \( 10^{-9} G_F \) to \( 0.1 G_F \).

The conversion probability \( P(M \rightarrow \bar{M}) \) is the quantity that is measured in experiments. It is related to the constant \( G_{M\bar{M}} \) in the following way \[60\]
\[
P(M \rightarrow \bar{M}) = \frac{\delta^2}{2\Gamma^2_\mu}, \quad (32)
\]
where
\[
\frac{\delta}{2} = \langle \bar{M} | H | M \rangle = \frac{16G_{M\bar{M}}}{\pi a^3} \quad (33)
\]
is a transition matrix element between the muonium and antimuonium states \((a \text{ is the radius of muonium atom})\) and \( \Gamma_\mu \) is the total decay width of muon.

From the point of view of SM extended by heavy neutrinos, \( M-\bar{M} \) conversion is not a good place to search for LFV. Roughly speaking, the \( M-\bar{M} \) amplitude is proportional to the square of the nondiagonal \( \mu-e \) mixing \( \sum_i B_{\mu N_i} B_{e N_i}^* \), which is strongly constrained by the measurements of processes \( \mu \rightarrow e\gamma, \mu \rightarrow eee \) and \( \mu \rightarrow e \) conversion. Amplitudes of the three processes depend approximately linearly on the nondiagonal \( \mu-e \) mixing. Therefore, if any of the experimental results of the three processes is improved by a factor \( a \), the experimental result for \( P(M \rightarrow \bar{M}) \) has to be improved by the factor \( a^2 \) to be competitive in finding LFV.
C. Extension and correction of some previous results

In this subsection some previous results on neutrinoless LFV processes evaluated within the frame of the V model are extended and/or corrected.

The decays of τ lepton into three leptons were evaluated within the V model in Ref. [18] without including terms with four $B_{iN}$-s. These terms were shown to dominate for large heavy neutrino masses in SM extended by two additional heavy Majorana neutrinos [11]. In that model the $B_{iN}$-s are completely determined by $s^*_L$ parameters and ratio of the heavy neutrino masses. Here, the upper bounds of complete amplitudes are evaluated within the V model, and used to find the upper bounds of the corresponding BRs.

Neutrinoless LFV decays of the Z boson were studied in Ref. [11] in SM extended with heavy Majorana neutrinos. The expressions for loop functions are given in Appendix A of that reference, and they are correct except for terms containing $\sqrt{w} \lambda Z \tan^{-1} \left( \frac{\sqrt{w}}{\lambda_i + \lambda_j - \lambda Z} \right)$, which should be replaced with the expression

$$\theta(w) \frac{\sqrt{w}}{\lambda Z} \left[ \tan^{-1} \left( \frac{\sqrt{w}}{\lambda_i + \lambda_j - \lambda Z} \right) + \pi \theta(\lambda Z - \lambda_i - \lambda j) \right]$$

$$+ \theta(-w) \frac{\sqrt{-w}}{\lambda Z} \left[ \frac{1}{2} \ln \left| \frac{\lambda Z - \lambda_i - \lambda j + \sqrt{-w}}{\lambda Z - \lambda_i - \lambda j - \sqrt{-w}} \right| - i\pi \theta(\lambda Z - \lambda_i - \lambda j) \right].$$

The notation is the same as in Ref. [11]. The theta function in the first square bracket was not taken into account in the analysis in Ref. [11]. As it contributes only for the heavy neutrino masses smaller than the Z-boson mass, the numerical results given there should not change. For heavy neutrinos lighter than Z-boson mass, the theta function assures the continuity of the loop functions in heavy neutrino masses. Here, LFV decays of the Z boson are studied in the V model. The terms containing the matrix elements $C^*_N_{i,N,j}$, that exist only for heavy Majorana neutrinos, are neglected. In the V model only the upper bounds of the $Z \rightarrow ll'$ amplitudes can be found. They are found using the formalism of the section III C.

The only three neutrinoless LFV processes that give additional constraints on $B_{iN}$-s, $\mu \rightarrow e\gamma$, $\mu \rightarrow eee$ and $\mu - e$ conversion, were examined in Ref. [12]. Their analysis has included the "nondecoupling" effects of heavy neutrinos, has indicated that a generalization of Appelquist–Carazzone theorem [44,45] is valid for the V model and has determined the limits on specific combinations of $B_{iN}$-s. The "proof" of the generalization of the Appelquist–Carazzone theorem is based on an introduction of a somewhat arbitrary maximal $SU(2)_L$-doublet mass term. The amplitude they present for $\mu \rightarrow e$ conversion does not include the photon exchange and box contributions, and the amplitude for $\mu \rightarrow eee$ does not include the photon exchange term. These terms are included here. Moreover, in their expression for $\mu \rightarrow 3e$ BR, obtained in the limit of large heavy neutrino masses, one has to make replacements $F_{e\mu} \rightarrow 2F_{e\mu}$ and $\varepsilon_L \equiv -1/2 + s^*_V \rightarrow -\varepsilon_L$, (the notation of Ref. [12] is used).

The neutrinoless LFV decay of $\pi^0$ was studied in Ref. [14] in extensions of SM with additional Majorana and additional Dirac neutrinos. The expressions for the extension with
Majorana neutrinos is correct, but the expressions for the extension by Dirac neutrinos is not, because the terms existing only for Majorana neutrinos were kept in the amplitude. The correct amplitude is obtained neglecting the terms containing the loop function $H_Z$. When this correction is made, the numerical results for the $\pi \to \mu e$ decay become $\sim 25$ times smaller.

V. ON LOW ENERGY NEUTRONOLESS LFV AMPLITUDES AND DECAY RATES

A. Loop functions included in LFV processes

In the lowest order of perturbation theory, amplitudes of neutrinoless LFV decays are built up from several building blocks (composite loop functions and tree-level functions) which may be denoted by the exchanged bosons, or by the type of the Feynman diagram: $\gamma$, $Z$, box (box containing only leptons, leptons and $u$ quarks, leptons and $d$ quarks), $H$ and $W^+W^-$. All functions except the last one are combinations of loop functions and $B_{lN_i}$s. $W^+W^-$ function is a tree-level function and it is strongly suppressed compared to the others [30]. $\gamma$, $Z$, box and $H$ functions comprise two-fermion currents. In the $\gamma$, $Z$ and $H$ functions only one of the fermion currents changes flavor, while in box functions flavors may be changed in both fermion currents. The classification of the neutrinoless LFV decays, given in Table I, is made according to the Feynman diagrams they contain and the approximations (physics) one has to use in finding the corresponding amplitudes. The references cited in Table I refer only to the calculations of LFV processes in the extensions of SM by additional heavy neutrinos.

If the heavy neutrino masses are larger than a few hundred GeV, the expressions for neutrinoless LFV decays simplify considerably. All amplitudes can approximately be expressed in terms of four combinations of masses and $B_{lN_i}$s,

\[
\begin{align*}
A_{\nu'} &= \sum_{N_i} B^*_{lN_i} B_{l'N_i}, \\
B_{\nu'} &= \sum_{N_i} B^*_{lN_i} B_{l'N_i} \ln \lambda_{N_i}, \\
C_{\nu'} &= \sum_{N_iN_j} B^*_{lN_i} C^*_{N_iN_j} B_{l'N_j} \frac{\lambda_{N_i} \lambda_{N_j}}{\lambda_{N_i} - \lambda_{N_j}} \ln \frac{\lambda_{N_i}}{\lambda_{N_j}}, \\
D_{\nu'l_1l_2} &= \frac{1}{2} \sum_{N_iN_j} B^*_{lN_i} B^*_{l'N_j} (B_{lN_i} B_{l'N_j} + B_{l'N_i} B_{lN_j}) \frac{\lambda_{N_i} \lambda_{N_j}}{\lambda_{N_i} - \lambda_{N_j}} \ln \frac{\lambda_{N_i}}{\lambda_{N_j}},
\end{align*}
\]

where $\lambda_{N_i} = m_{N_i}^2/m_W^2$. The building blocks mentioned above, expressed in terms of combinations [30], read

\[
\begin{align*}
G_{\gamma\nu'}^W &\approx \frac{1}{2} A_{\nu'}, \\
F_{\gamma\nu'}^W &\approx -\frac{1}{6} B_{\nu'}, \\
F_{Z\nu'}^W &\approx -\frac{3}{2} B_{\nu'} - \frac{1}{2} C_{\nu'},
\end{align*}
\]
It is convenient to introduce four combinations of $B$ masses, the function $C$ also valid for large, nondegenerate heavy neutrino masses. Second, for degenerate neutrino masses the dominance of the functions with quadratic mass dependence of the amplitude leads to the transient, so called "nondecoupling behaviour" of amplitudes. As explained where $\lambda_x = m_x^2/m_W^2$, $x = b, t, H$.

For the important case of degenerate ($\lambda_N = \lambda_N$) and large heavy neutrino masses the functions (36) can be written in terms of parameters $s^\nu_L$ and $x^0_L$, 

$$
A_L^\nu = s^\nu_L s^\nu_L x^0_L, \\
B_L^\nu = s^\nu_L s^\nu_L x^0_L \ln \lambda_N, \\
C_L^\nu = s^\nu_L s^\nu_L \sum_{i=1}^{n_G} (s^\nu_L)^2 x^0_{L_i} x^0_{L_i} \lambda_N, \\
D_L^\nu t = \frac{1}{2} s^\nu_L s^\nu_L s^\nu_L s^\nu_L x^0_{ll_1 x^0_{ll_2}} (x^0_{LL_1 x^0_{LL_2}} + x^0_{LL_1 x^0_{LL_2}}) \lambda_N.
$$

It is convenient to introduce four combinations of $B_{ln}$-s, heavy neutrino masses, $\lambda_N^{PUB}$ and upper bound values for $s^\nu_L$ parameters (4), denoted by $\tilde{s}^\nu_L$

$$
\begin{align*}
A_L^\nu &= \tilde{s}^\nu_L \tilde{s}^\nu_L x^0_L, \\
B_L^\nu &= \tilde{s}^\nu_L \tilde{s}^\nu_L x^0_L \ln \lambda_N^{PUB}, \\
C_L^\nu &= \tilde{s}^\nu_L \tilde{s}^\nu_L \sum_{i=1}^{n_G} (\tilde{s}^\nu_L)^2 \lambda_N^{PUB}, \\
D_L^\nu t = \frac{1}{2} \tilde{s}^\nu_L \tilde{s}^\nu_L \tilde{s}^\nu_L \tilde{s}^\nu_L x^0_{ll_1 x^0_{ll_2}} (x^0_{ll_1 x^0_{ll_2}} + x^0_{ll_1 x^0_{ll_2}}) \lambda_N^{PUB}. 
\end{align*}
$$

Any of these combinations is always smaller than one.

Here, few comments are in order. First, it is obvious that $|D_L^\nu t| \leq |C_L^\nu|$ (the relation is also valid for large, nondegenerate heavy neutrino masses). Second, for degenerate neutrino masses, the function $C_L^\nu$ becomes larger than the functions $A_L^\nu$ and $B_L^\nu$ if

$$
\begin{align*}
\lambda_N &\geq \frac{1}{\sum_{i=1}^{n_G} (s^\nu_L)^2} \\
\lambda_N &\geq \frac{\ln \lambda^0_N}{\sum_{i=1}^{n_G} (s^\nu_L)^2},
\end{align*}
$$

respectively. The dominance of the functions with quadratic mass dependence of the amplitude leads to the transient, so called ”nondecoupling behaviour” of amplitudes. As explained...
in section III D decoupling follows from PUB inequalities (13). A typical mass value for which the quadratic terms become larger than the logarithmic terms is \( m_N \sim 1500 \, \text{GeV} \) for \( s_L^\nu \) values of the order of the present experimental bounds (4). Third, at the maximal \( \lambda_N \) value permitted by the PUB \( (\lambda_N^{\text{PUB}}) \), the function \( C_{ll'} \) depends essentially only on two diagonal mixing parameters, \( s_L^\nu \) and \( s_L^{\nu'} \),

\[
C_{ll'}(\lambda_N^{\text{PUB}}) = \frac{4n_R \sum_i (s_L^\nu)^2 x_{ll'r}^0 x_{ll'r}^0}{\alpha_W \sum_i (s_L^\nu)^2} s_L^\nu s_L^{\nu'} \lesssim \frac{4n_R s_L^\nu s_L^{\nu'} x_{ll'}^0}{\alpha_W A_{ll'}}.
\]  

(41)

Therefore, at \( m_N = m_N^{\text{PUB}} \) all amplitudes depend essentially only on \( s_L^\nu \) and \( s_L^{\nu'} \). If both the logarithmic and quadratic mass terms are present in LFV amplitude, at \( m_N^{\text{PUB}} \) logarithmic terms contribute up to \( \sim 10\% \) of the total amplitude. Fourth, if the \( t \) quark contribution is multiplied by small CKM matrix elements, box amplitudes may have large contribution coming from \( c \) quark in the loop expressions. For instance, in the processes \( \tau \to e P^0/\mu P^0 \) \( c \) quark contribution to the amplitude is \( \sim 13\% \). Fifth, the processes containing only the function \( A_{ll'} \) are most suitable for obtaining new information on \( B_{ll'} \) parameters, because they are almost independent of heavy neutrino masses. Sixth, for degenerate heavy neutrinos the dependence of LFV amplitudes on LCKM matrix elements appears only through six sums \( \sum_i B_{ll_i} B^*_{ll_i} \), \( l \neq l' \) and \( \sum_i |B_{ll_i}|^2 \) (diagonal and nondiagonal mixings). Writing the sums in terms of \( s_L^{\nu_i} \)-s and \( x_{ll'r}^0 \)-s, one can easily show that if some LFV amplitude tends to zero for \( s_L^\nu \to 0 \), then the amplitude tends to zero for \( x_{ll'r}^0 \to 0 \), \( l \neq l' \), too. (Strictly speaking reduction of a parameter \( s_L^\nu \) by factor \( a \) is equivalent to the reduction \( x_{ll'r}^0 \to a^2 x_{ll'r}^0 \) and \( x_{ll'r}^0 \to ax_{ll'r}^0 \) \( l \neq l' \), but, by definition, \( x_{ll'r}^0 = 1 \).) This analysis shows that LFV amplitudes may be reduced without changing the diagonal mixing parameters \( s_L^\nu \). It also indicates that the absolute values of LFV amplitudes may attain any value between zero and the upper bound value. Therefore, LFV processes are unsuitable for finding the limits on the diagonal mixing parameters \( s_L^\nu \).

B. Approximative expressions for BRs in the large-mass limit and relations between them

Keeping only the leading terms in the large-mass limit of heavy neutrinos, the expressions for BRs of neutrinoless LFV decays may be expressed in terms of the functions (36). In the following these expressions are listed. The definitions of unknown quantities are given below the list.

\[
B(l \to l'\gamma) \approx \frac{\alpha_W^2 s_W^2}{210 \pi^2} \frac{m_\nu^5}{M_W^4 \Gamma_l} |A_{ll'}|^2;
\]

(42)

\[
B(l^- \to l'^- l_1^- l_2^+, l_1 = l_2 \neq l') \approx \frac{\alpha_W^4}{3 \times 25 \pi^3} \frac{m_\nu^5}{M_W^4 \Gamma_l} \left( |D_{ll'l_1l_2} - (1 - 2s_W^2)C_{ll'}|^2 + |2s_W^2C_{ll'}|^2 \right),
\]

\[
B(l^- \to l'^- l_1^- l_2^+, l' = l_1 = l_2) \approx \frac{\alpha_W^4}{3 \times 25 \pi^3} \frac{m_\nu^5}{M_W^4 \Gamma_l} \left( |D_{ll'l_1l_2} - 2(1 - 2s_W^2)C_{ll'}|^2 + \frac{1}{2} |4s_W^2C_{ll'}|^2 \right),
\]

\[
B(l^- \to l'^- l_1^- l_2^+, l_2 \neq l', l_1) \approx \frac{\alpha_W^4}{3 \times 216 \pi^3} \frac{m_\nu^5}{M_W^4 \Gamma_l} |D_{ll'l_1l_2}|^2;
\]

(43)

18
\[
B(Z \rightarrow l^- l'^+ + l'^- l^+) \approx \frac{\alpha^3_W}{3 \times 2^8 c^2_W} \frac{M_W}{\Gamma_Z} |C_{ll}|^2; \tag{44}
\]

\[
R(\mu^- \text{Ti} \rightarrow e^- \text{Ti}) \approx \frac{\alpha^4_W \alpha^3_{em}}{2^{10} \pi^2} Z_{eff} F(-m^2_\mu) |Q^2_W| \frac{m^5_\mu}{M^4_W \Gamma_{\text{capture}}} |C_{\mu e}|^2; \tag{45}
\]

\[|G_{M\ell}| \approx \frac{\alpha^2_W}{2^5 M^4_W} |D_{\mu ee\mu}|; \tag{46}\]

\[
B(\tau \rightarrow l P^0, \text{cqf}) \approx \frac{\alpha^4_W (\alpha^2_{P^0})^2}{2^{13} \pi} \left(1 - \frac{m^2_{P^0}}{m^2_\tau}\right)^2 \frac{m^2_\tau f^2_{P^0}}{M^2_W \Gamma_\tau} |C_{ll}|^2, \tag{47}\]

\[
B(\tau \rightarrow l V^0, \text{cqf}) \approx \frac{\alpha^4_W (\alpha^2_{V^0})^2}{2^{13} \pi} \left(1 - \frac{m^2_{V^0}}{m^2_\tau}\right)^2 \left(1 + 2 \frac{m^2_{V^0}}{m^2_\tau}\right) \frac{m^3_{\tau} m^2_{V^0}}{M^4_W \Gamma_\tau} |C_{ll}|^2, \tag{48}\]

\[
B(\tau \rightarrow l P^0, \text{ncqf}) \approx \frac{\alpha^4_W (\alpha^2_{P^0, \text{ds}})^2}{2^{11} \pi} \left(1 - \frac{m^2_{P^0}}{m^2_\tau}\right)^2 \frac{m^2_\tau f^2_{P^0}}{M^2_W \Gamma_\tau} |F_{\text{Pbox}}|^2, \tag{49}\]

\[
B(\tau \rightarrow l V^0, \text{ncqf}) \approx \frac{\alpha^4_W (\alpha^2_{V^0, \text{ds}})^2}{2^{11} \pi} \left(1 - \frac{m^2_{V^0}}{m^2_\tau}\right)^2 \left(1 + 2 \frac{m^2_{V^0}}{m^2_\tau}\right) \frac{m^2_\tau m^2_{V^0}}{M^4_W \Gamma_\tau} |F_{\text{Vbox}}|^2; \tag{50}\]

\[
B(P^0 \rightarrow e\mu, \text{cqf}) \approx \frac{\alpha^4_W (\alpha^2_{P^0})^2}{2^{12} \pi} \left(1 - \frac{m^2_\mu}{m^2_{P^0}}\right)^2 \frac{m_{P^0} m_\mu f^2_{P^0}}{M^2_W \Gamma_{P^0}} |C_{\mu e}|^2, \tag{51}\]

\[
B(P^0 \rightarrow e\mu, \text{ncqf}) \approx \frac{\alpha^4_W (\alpha^2_{P^0, \text{ds}})^2}{2^{10} \pi} \left(1 - \frac{m^2_\mu}{m^2_{P^0}}\right)^2 \frac{m_{P^0} m_\mu f^2_{P^0}}{M^2_W \Gamma_{P^0}} |F_{\mu e\mu\text{ds}}|^2, \tag{52}\]

\[
B(\mathcal{H}^0 \rightarrow ll') \approx \frac{\alpha^4_W}{2^{10} \pi} \left(1 - \frac{m^2_{\mathcal{H}^0}}{m^2_{l'}}\right)^2 \frac{m_{H^0} m_{l'} f^2_{\mathcal{H}^0}}{M^4_W \Gamma_{\mathcal{H}^0}} |F_{\text{Hbox}}|^2; \tag{53}\]

\[
B(\tau \rightarrow l P_1 P_2, \text{cqf}) \approx \frac{\alpha^4_W}{2^{16} \pi^3} \int_{(m_{P_1} + m_{P_2})^2} \frac{M^4_W m^2_\tau \Gamma_\tau}{M^4_W m^2_\tau \Gamma_\tau} |C_{ll}|^2, \tag{54}\]

\[
B(\tau \rightarrow l P_1 P_2, \text{ncqf}) \approx \frac{\alpha^4_W (\alpha^2_{K^0, \text{sd}})^2}{2^{14} \pi^3} \frac{|C_{K^0, P_1 P_2}|^2}{|F_{\text{Kbox}}|^2} \int_{(m_{P_1} + m_{P_2})^2} \frac{M^4_W m^2_\tau \Gamma_\tau}{M^4_W m^2_\tau \Gamma_\tau} |C_{ll}|^2, \tag{55}\]

\[
B(\tau \rightarrow l P_1 P_2, \text{cqfH}) \approx \frac{\alpha^4_W}{2^{16} \pi^3} \frac{M^4_{H P_1 P_2}}{M^4_W M^4_{\tau} \Gamma_{\tau}} \int_{(m_{P_1} + m_{P_2})^2} \frac{3}{2} |C_{ll}|^2; \tag{56}\]
\[
B(K_W \to \pi^\pm e^\mp) \approx \frac{\alpha W^2}{2^{11} \pi^3} \int_{(m_\mu-m_e)^2}^{(m_{K_W}-m_e)^2} dt \frac{[A_{++} f_+^2 + A_{--} f_-^2 + A_{+-} f_+ f_-]}{M_W^4 m_{K_W}^4 \Gamma_{K_W}} |F_{box}|^2, \quad (57)
\]

\[
B(H_a \to Pl'^{-}l'^{+}) \approx \frac{\alpha W^2}{2^{11} \pi^3} \int_{(m_{l'}-m_l)^2}^{(m_{H_a}-m_{l'})^2} dt \frac{[a^2 Z P_1 + a_P b_P Z P_2 + b_P^2 Z P_3]}{M_W^4 m_{H_a}^4 \Gamma_{H_a}} |F_{box}^{ll'}|^2, \quad (58)
\]

\[
B(H_a \to Vl'^{-}l'^{+}) \approx \frac{\alpha W^2}{2^{11} \pi^3} \left|F_{box}^{ll'}\right|^2 \int_{(m_{l'}-m_l)^2}^{(m_{V}-m_{l'})^2} dt \frac{[a^2 Z V_1 + b^2 Z V_2 + c^2 Z V_3 + d^2 Z V_4 + a V c V Z V_5 + b V c V Z V_6 + b V d V Z V_7 + c V d V Z V_8]}{M_W^4 m_{H_a}^4 \Gamma_{H_a}}; \quad (59)
\]

\[
B(B \to B'\mu) \approx \frac{\alpha W^2}{2^{10} \pi^3} \left|F_{box}\right|^2 \frac{1}{M_W^4 m_{B'}^4 \Gamma_B} \int_{(m_{B'}-m_B)^2}^{(m_{B'}+m_B)^2} dt \left[A_1 (f_1^2 + g_1^2) + A_2 (f_1^2 - g_1^2) + A_3 (f_1 g_1) + A_4 (g_1 g_3) + A_5 (g_3^2)\right]. \quad (60)
\]

All expressions are written in terms of products of dimensionless factors. For the expressions containing the dominant term $C_{l''}$, the error one makes by keeping only the dominant term is of the order $\gtrsim 20\%$, because the term $C_{l''}$ is always accompanied with the $B_{l''}$ term giving $\sim 10\%$ contribution to the amplitude at $m_{NPUB}$. Following abbreviations are used: $s_W = \sin \theta_W$, $c_W = \cos \theta_W$ ($\theta_W$ is Weinberg’s angle), $s_P = \sin \theta_P$, $c_P = \cos \theta_P$ ($\theta_P$ is the mixing angle for pseudoscalar nonet states) and $s_V = \sin \theta_P$, $c_V = \cos \theta_P$ ($\theta_V$ is the mixing angle for vector nonet states). In Eq. \([13]\) $\alpha_{em} = 1/137$ is the fine structure constant, $Z$ is atomic number (for $^{48}_{22}Ti$ $Z = 22$, $N = A - Z = 26$), $Z_{eff} = 17.6$ \([71, 72]\) is the effective atomic number of $Ti$ \([73]\), $F(-m_\mu^2) = 0.54$ is its nuclear form factor \([72, 73]\) at momentum transfer $q^2 \approx -m_\mu^2$ \([70]\), $Q_W = Z(1 - 4s_W^2) - N$ is the coherent nuclear charge associated with coupling of $Z$ boson to nucleus \([71]\) and $\Gamma_{capture}$ is the capture rate for negative muons on Ti \([71, 72, 73]\). In Eqs. \([47, 53]\) $f_P$ and $f_H$ are decay constants of light and heavy pseudoscalar mesons respectively, and $\gamma_{V'}$ are constants defining the decay constants for light vector mesons, $f_V = m_V/\gamma_V$. The normalizations used here are

\[
A_{P'}(x) = i f_P \partial^\mu P(x),
\]

\[
V_{V'}(x) = \begin{cases} 
\frac{m^2_{V'}}{\gamma_N} V^\mu(x) & \text{for light vector mesons}, \\
\frac{1}{f_V m_V} V^\mu(x) & \text{for heavy vector mesons},
\end{cases}
\]

where $A_{P'}$ and $V_{V'}$ are the axial vector (vector current) with the same quark content as corresponding pseudoscalar meson $P(x)$ and vector meson $V(x)$ fields, respectively. $\alpha_{Z'}^2$, 

20
\[ \alpha_{V^0}, \alpha_{P^0 A_0}^{box, d} \text{ and } \alpha_{V^0}^{box, d} \text{ are constants defining the meson content in vector and axial-vector quark currents contained in quark combinations in the } Z- \text{ and } box- \text{ amplitude. They are defined in Table II. The mass of the lighter lepton is neglected in the expressions } \text{(17-73). The composite loop function } F_{box}^{\mu \nu, a, b} \text{ contains two terms of approximatively equal magnitude, for brevity the expressions of these BRs are not written in terms of the functions } \text{(38). The expressions } \text{(54-56)} \text{ contain three body phase integrals. The phase functions may be found in the following references: } \alpha, \beta, \gamma \text{ and } \eta \text{ in Ref. } \text{(66)}; A_{1+, 1-} \text{ and } A_{--} \text{ in Ref. } \text{(10)}; A_1, A_2, A_3, A_4 \text{ and } A_5 \text{ in Ref. } \text{(10)}. \text{ In Eq. } \text{(54)}, C_{V^0P_1P_2} = g_{\rho^+ \rho^-} c_{V^0P_1P_2} \text{ are constants stemming from the gauged chiral } U(3)_L \times U(3)_R / U(3)_V \text{ Lagrangian } \text{(66)} \text{ (e.g. } c_{\rho^+ \rho^-} = 1), \text{ and }
\]

\[
\frac{p_{BW}^{V^0}}{\gamma_{V^0}}(q) = \frac{1}{\gamma_{V^0}} \frac{m_{V^0}^2 - i\Gamma_{V^0} m_{V^0} - q^2}{m_{V^0}^2 - i\Gamma_{V^0} m_{V^0} - q^2} = \frac{1}{\gamma_{V^0}} p_{BW}^{V^0, norm}(q) \tag{62}
\]

is the Breit-Wigner propagator for a vector meson \( V^0 \) multiplied by slightly modified expression \( m_{V^0}^2 / \gamma_{V^0} \). The modification of the expression \( m_{V^0}^2 / \gamma_{V^0} \) is made to obtain \( p_{BW}^{V^0, norm}(0) = 1 \text{(66, 73, 80)} \). The constant \( g_{\rho^+ \rho^-} \) is equal to the \( \rho \) self coupling constant \( g_\rho \) from section IV A. In Eq. \( \text{(60)} \) \( M_{H^0, P_1, P_2}^2 \) are mass parameters contained in the effective Higgs–meson Lagrangian \( \text{(66)} \).

\[
\mathcal{L}_{HMM} = \frac{g_W}{4M_W} \left[ m_{\rho^0}^2 (m_{\pi^0}^2 + 2\pi^+ \pi^-) + 2m_{K^+}^2 K^+ K^- + 2m_{K^0}^2 K^0 \bar{K}^0 + \frac{m_{K^+}^2 + m_{K^0}^2 + m_{\eta}^2}{3} m_{\pi^0}^2 \right]
+ \frac{2m_{K^+}^2 + 2m_{K^0}^2}{3} m_{\eta}^2 + \left[ 23/2 (2m_{\pi^-}^2 - m_{K^+}^2 - m_{K^0}^2) \right] m_{\eta}^2 \eta \eta \tag{63}
\]

obtained by comparing the quark mass Lagrangian with the corresponding term in the chiral Lagrangian \( \text{(81)} \) (e.g. \( M_{H^0, \pi^+}^2 = 2m_{\pi^+}^2 \equiv 2(2m_{\pi^+}^2 + m_{\pi^-}^2)/3 \)). In Eq. \( \text{(57)} \) \( \hat{c}_{K^0 K W} = ac_{K^0 K S} \pi + bc_{K^0 K S} \pi \) \( (K_W = a\bar{K}_S + bK_S \text{ is a weak kaon eigenstate, and } K_S \text{ is a mass eigenstate}) \). In Eq. \( \text{(60)} \) \( f_1, g_1 \) and \( g_3 \) are baryon form factors. The other baryon form factors do not contribute, because they belong to the second class currents, or give a contribution proportional to the difference of baryon masses. The form factors \( f_1 \) and \( g_1 \) can be defined in terms of two \( SU(3) \) Clebsch-Gordan coefficients and two reduced matrix elements corresponding to symmetric and antisymmetric octet \( SU(3) \) representations. These reduced matrix elements are almost independent of momentum transfer and are usually identified with their value at zero momentum transfer, \( D \) and \( F \). The functions \( g_1 \) and \( g_3 \) are not independent, but correlated through the Goldberger-Treiman relation \( \text{(10)} \).

All approximative expressions for the BRs \( \text{(12-74)} \), valid in the large mass limit, except \( B(l^+ \rightarrow l^- l_1 l_2, l_1 = l_2 \neq l') \) and \( B(l^- \rightarrow l^- l_1 l_2, l_1 = l_2) \), depend only on one of the functions \( \text{(36)} \). In the following, the smaller of two dominant functions \( \mathcal{D}_{W l_1 l_2} \) will be neglected in the two exceptional expressions. The maximal error one makes in the evaluation of BRs of the exceptional processes is \( \sim 40\% \). With those approximations, the ratios of BRs having the same dominant function \( \text{(66)} \) become independent of the \( V \)-model parameters:

a) BRs with \( F_{Z}^{\mu \nu} (C_{\mu \nu}) \):

\[
R(\mu Ti \rightarrow e Ti) : B(\mu \rightarrow e e^- e^+) : B(Z \rightarrow \mu^\mp e^\pm) : B(\pi^0 \rightarrow \mu^\mp e^\pm) : B(\eta \rightarrow \mu^\mp e^\pm) = 1 : 5.60 \times 10^{-2} : 3.77 \times 10^{-2} : 6.05 \times 10^{-10} : 1.69 \times 10^{-11}, \tag{64}
\]
b) BRs with $F_{Z}^{d}$ ($C_{ct}$):

\[
B(Z \to \tau^{\mp}l^{\pm}) : B(\tau \to l\pi^{0}) : B(\tau \to l\rho^{0}) : B(\tau \to l\pi^{+}\pi^{-}) : B(\tau \to l\phi)
\]
\[
: B(\tau \to ll^{-}l^{+}) : B(\tau \to ll^{-}l^{+}) : B(\tau \to lK^{+}K^{-}) : B(\tau \to lK^{0}\bar{K}^{0}) : B(\tau \to ll')
\]
\[
: B(\tau \to l\eta) : B(\tau \to l\omega) : B(\tau \to l\eta\eta) : B(\tau \to l\pi^{0}\pi^{0})
\]
\[
= 1 : 3.40 \times 10^{-1} : 3.17 \times 10^{-1} : 2.83 \times 10^{-1} : 2.81 \times 10^{-1}
\]
\[
: 2.64 \times 10^{-1} : 1.64 \times 10^{-1} : 1.20 \times 10^{-1} : 7.43 \times 10^{-2} : 6.15 \times 10^{-2}
\]
\[
: 4.72 \times 10^{-2} : 8.78 \times 10^{-3} : 4.34 \times 10^{-12} : 5.50 \times 10^{-13}, \quad (65)
\]

c) BRs with $F_{box}^{-}\mu\nu_{ed}$

\[
B(K_{L} \to \mu^{\mp}e^{\pm}) : B(K^{+} \to \pi^{\mp}\mu^{\mp}e^{\pm}) : B(\Sigma^{+} \to p\mu^{\mp}e^{\pm}) : B(\Xi^{0} \to \Lambda\mu^{\mp}e^{\pm})
\]
\[
: B(A \to n\mu^{\mp}e^{\pm}) : B(\Xi^{-} \to \Sigma^{-}\mu^{\mp}e^{\pm}) : B(\Xi^{0} \to \Sigma^{0}\mu^{\mp}e^{\pm}) : B(\Sigma^{0} \to n\mu^{\mp}e^{\pm})
\]
\[
= 1 : 3.01 \times 10^{-2} : 1.30 \times 10^{-4} : 1.21 \times 10^{-4}
\]
\[
: 8.66 \times 10^{-5} : 6.40 \times 10^{-7} : 4.07 \times 10^{-7} : 6.31 \times 10^{-14}, \quad (66)
\]

d) BRs with $F_{box}^{-}\mu\nu_{ed}$

\[
B(B^{-} \to \pi^{-}\mu^{\mp}e^{\pm}) : B(B^{0} \to \mu^{\mp}e^{\pm}) = 1 : 3.76 \times 10^{-4}, \quad (67)
\]

e) BRs with $F_{box}^{-}\mu\nu_{bs}$

\[
B(B^{-} \to K^{*-}\mu^{\mp}e^{\pm}) : B(B^{0} \to K^{*0}\mu^{\mp}e^{\pm}) : B(\bar{B}^{0}_{s} \to \eta'\mu^{\mp}e^{\pm}) : B(\bar{B}^{0}_{s} \to \phi\mu^{\mp}e^{\pm})
\]
\[
: B(B^{-} \to K^{-}\mu^{\mp}e^{\pm}) : B(\bar{B}^{0} \to K^{0}\mu^{\mp}e^{\pm}) : B(\bar{B}^{0}_{s} \to \eta\mu^{\mp}e^{\pm}) : B(\bar{B}^{0}_{s} \to \mu^{\mp}e^{\pm})
\]
\[
= 1 : 9.34 \times 10^{-1} : 8.83 \times 10^{-1} : 8.57 \times 10^{-1}
\]
\[
: 7.92 \times 10^{-1} : 7.47 \times 10^{-1} : 3.31 \times 10^{-1} : 4.93 \times 10^{-4}, \quad (68)
\]

f) BRs with $F_{box}^{-}\tau\nu_{ds}$

\[
B(\tau \to e\pi^{+}K^{-}) : B(\tau \to eK^{*0}) : B(\tau \to eK^{0}) = 1 : 7.32 \times 10^{-1} : 2.99 \times 10^{-1}, \quad (69)
\]

g) BRs with $F_{box}^{-}\tau\nu_{bd}$

\[
B(B^{-} \to \pi^{-}\tau^{\mp}e^{\pm}) : B(\bar{B}^{0} \to \tau^{\mp}e^{\pm}) = 1 : 1.14 \times 10^{-1}, \quad (70)
\]

h) BRs with $F_{box}^{-}\tau\nu_{bs}$

\[
B(B^{-} \to K^{*-}\tau^{\mp}e^{\pm}) : B(\bar{B}^{0} \to K^{*0}\tau^{\mp}e^{\pm}) : B(\bar{B}^{0}_{s} \to \phi\tau^{\mp}e^{\pm}) : B(\bar{B}^{0}_{s} \to \eta'\tau^{\mp}e^{\pm})
\]
\[
: B(B^{-} \to K^{-}\tau^{\mp}e^{\pm}) : B(\bar{B}^{0} \to K^{0}\tau^{\mp}e^{\pm}) : B(\bar{B}^{0}_{s} \to \eta\tau^{\mp}e^{\pm}) : B(\bar{B}^{0}_{s} \to \tau^{\mp}e^{\pm})
\]
\[
= 1 : 9.37 \times 10^{-1} : 8.10 \times 10^{-1} : 6.57 \times 10^{-1}
\]
\[
: 6.54 \times 10^{-1} : 6.16 \times 10^{-1} : 2.76 \times 10^{-1} : 1.63 \times 10^{-1}. \quad (71)
\]

For each group of BRs the BRs are lined up in the descending order. For instance, $\mu \to e$ conversion is the most suitable for finding LFV in the group containing the composite loop function $F_{Z}^{ev}$. The position in the group depends on the coupling constants, phase factors and the total decay rate of the decaying particle. For instance, the BRs for $\tau \to lP_{1}P_{2}$
processes containing $Z$-boson amplitude are $\sim 10^{12}$ times larger than BRs of the processes $\tau \to lP_1P_2$ containing only Higgs amplitude, because of the small Higgs-meson couplings, although the dominant composite loop functions are essentially the same. The ratios (84-87) are given for measured processes and LFV processes that have not been studied in models with additional heavy neutrinos before. The $l \to l'\gamma$ decays are not included in the above ratios, because each process $l \to l'\gamma$ forms a group for itself, depending only on the function $A_l$. The numerical results for the ratios of BRs agree quite well with the exact ratios for degenerate heavy neutrino masses obtained at $m_N = m_{NPU}$. That allows one to consider only one of the decays of each group when comparing theoretical and experimental results.

Besides the ratios of BRs having the same dominant function (84), it is useful to have relations that relate BRs of different groups of decays. These relations generally depend on the matrix elements of $B$ matrix and CKM matrix. For instance,

$$B(Z \to \tau^+\tau^-) : B(Z \to \tau^+\mu^-) : B(Z \to \mu^+\tau^-)$$

$$= |F_Z^{\tau\tau}|^2 : |F_Z^{\tau\mu}|^2 : |F_Z^{\mu\tau}|^2,$$

$$B(\tau \to eP^0) : B(\tau \to \mu P^0) : B(P^0 \to e^{\mp}\mu^\pm)$$

$$= \left\{ \begin{array}{ll}
|F_Z^{\tau\ell}|^2 : |F_Z^{\tau\mu}|^2 : |F_Z^{\mu\tau}|^2 & \text{for}\ cqf, \\
|F_{box}^{\tau\mu}|^2 : |F_{box}^{\tau\mu}|^2 : |F_{box}^{\mu\tau}|^2 & \text{for}\ ncqf,
\end{array} \right.$$}

$$B(\tau \to e\gamma) : B(\tau \to \mu\gamma) : B(\mu \to e\gamma)$$

$$= |B_{\tau N}^{*} B_{eN}|^2 : |B_{\tau N}^{*} B_{\mu N}|^2 : |B_{\mu N}^{*} B_{eN}|^2,$$

$$B(\tau \to ee^{\mp}\ell^{\pm}) : B(\tau \to \mu\mu^{\mp}\ell^{\pm}) : B(\mu \to ee^{\mp}\ell^{\pm})$$

$$\approx |F_Z^{\tau\ell}|^2 : |F_Z^{\tau\mu}|^2 : 5.63|F_Z^{\mu\ell}|^2,$$

$$B(\tau \to eK^{+}\pi^{-}) : B(\tau \to \mu K^{+}\pi^{-}) : B(K^{-} \to \pi^{-}\mu^{\mp}e^{\pm})$$

$$= |F_{box}^{\tau\mu}|^2 : 0.983|F_{box}^{\tau\mu}|^2 : 6.82|F_{box}^{\mu\ell}|^2,$$

$$B(B_l \to l_{12}^{\pm}) : B(B_{j} \to l_{12}^{\pm} l_{12}^{\pm}) = |F_{box}^{l_{12}}|^2 : |F_{box}^{l_{12}}|^2 \quad q_i, q_j = u, d, s. \quad (72)$$

BRs of processes having only the logarithmic dependence on mass are several orders of magnitude smaller than BRs containing the quadratic mass dependent terms. In the processes containing quarks in the final state, the presence of small CKM matrix elements additionally reinforces this difference. E.g., at $m_{NPU}$

$$B(l \to l'\gamma) : B(l \to l'_{12} l_{12}) \lesssim 10^{-2},$$

$$B(\tau^{-} \to e^{-}K^{0}) : B(\tau^{-} \to e^{-}\pi^{0}) \approx B(\tau^{-} \to e^{-}\pi^{+}K^{-}) : B(\tau^{-} \to e^{-}\pi^{-}\pi^{+}) \lesssim 10^{-9}. \quad (73)$$

Between the LFV decays having the box contribution only, the $B$-meson decays have the largest CKM matrix elements. For that reason they might be the most suitable box-dominated processes for finding LFV in the future $B$-factories.

C. Numerical results, comparison with experiment and discussion

In this subsection the experimental upper bounds for the measured neutrinoless LFV BRs are compared with the theoretical upper bounds obtained in the $V$ model. For some
interesting unmeasured processes, the theoretical upper bounds are given, too. The results are discussed. The limit on the nondiagonal $\mu$-$e$ mixing is updated. The decoupling of very heavy neutrinos is shown explicitly. The possible error one can make using the upper bound procedure given in the section is estimated.

Theoretical results depend on the $V$-model parameters: "diagonal" mixings $s_{LL}^\nu$, phases of $B_{iN}$'s and heavy neutrino masses. The parameters $s_{LL}^\nu$ must satisfy the experimental upper bounds, the heavy neutrinos are bound by the PUB inequalities, while the phases of $B_{iN}$ matrices are undetermined. The numerical results are largest for degenerate neutrino masses at maximal values of $s_{LL}^\nu$ parameters and maximal neutrino mass, $m_{N_{\text{PUB}}}$. For degenerate heavy neutrino masses the phase dependence of $B_{iN}$ matrices is contained in the parameters $x_{ll'}$.

The numerical values for BRs and $G_{M\overline{M}}$ depend on a number of "SM" particle properties, too: decay rates of particles, masses of the particles included in the decays, CKM matrix elements, decay constants of mesons, quark masses included in loops, mixing angles, various couplings, etc. Almost all these quantities are taken from Ref. [36], or derived from the data given there. For instance, masses of the $u$, $d$, $s$, $c$ and $b$ quarks are taken to be equal to the average of the upper and lower bound values. The CKM matrix elements are derived in the same way. The $t$ quark mass is set to be equal to the experimental value obtained from the direct observations of $t$ quark. For pseudoscalar meson decay constants of light mesons we took the values partly from Ref. [36] and partly from Ref. [82],

$$f_{\pi^+} = 130.7 \text{ MeV}, \quad f_{K^+} = 159.8 \text{ MeV}, \quad f_{\pi^0} = 119 \text{ MeV}, \quad f_{\eta} = 131 \text{ MeV} \quad \text{and} \quad f_{\eta'} = 118 \text{ MeV}.$$  \hfill (74)

Due to the isospin symmetry, $f_{K^0} = f_{\overline{K}^0} = f_{K^\pm}$. The constants $\gamma_{V\alpha}$, defining the decay constants of light vector mesons, are extracted from the $V^0 \rightarrow e^+e^-$ decay rates

$$\gamma_{\rho^0} = 2.518, \quad \gamma_{\phi} = 2.933, \quad \gamma_{\omega} = 3.116,$$  \hfill (75)

or estimated using the SU(3) octet symmetry, $\gamma_{K^0} = \gamma_{\rho^0}$. For all decay constants of $D$ and $D^*$ mesons, the conservative value $200 \text{ MeV}$ is taken. The decay constants of $B$ and $B^*$ mesons are derived using the scaling law for decay constants derived from HQET,

$$f_{H} \sim m_{H}^{-1/2}.$$  \hfill (76)

The weak fine-structure constant is defined as $\alpha_W = \alpha_{em} / \sin^2 \theta_W$, with $\cos \theta_W = M_W / M_Z$. The $\rho - \pi - \pi$ coupling constant (which is equal to the $\rho$ meson self coupling constant) is derived from the $\rho \rightarrow 2\pi$ coupling width. Other vector-meson–pseudoscalar-meson couplings of light mesons are fixed by one of the chiral model Lagrangians [57,56]. The mixing of the vector-meson nonet states is determined from the quadratic Gell-Mann–Okubo mass formula, $\theta_V = 39.3^\circ$. The mixing of the pseudoscalar-meson nonet states is extracted from the $e^+e^- \rightarrow e^+e^-\gamma^* \rightarrow e^+e^- (P \rightarrow \gamma \gamma)$ experiments, $\theta_P = -23^\circ$. The only "SM" parameters that are not firmly established are "HQET+CHPT" parameters describing the semileptonic LFV decays of the $B$-mesons, $g$, $\beta$, $\lambda$, $\alpha_1$ and $\alpha_2$ (see section IV A). The corresponding parameters for $D$-mesons have been determined by fitting the theory to the experimental values of the semileptonic decays of $D$ mesons [56,54,53]. The $B$-meson parameters $\lambda$, $\alpha_1$ and $\alpha_2$ may be derived from the $D$-meson parameters from the scaling laws.
for the vector and axial current \([11]\). The parameter \(g\) is independent of a heavy quark mass, and the value of parameter \(\beta\) is consistent with zero. The best \(B\)-meson parameters obtained using the above procedure are \([83]\),

\[
g = 0.2, \quad \beta = 0, \quad \lambda = -0.34 \text{ GeV}^{-1}, \\
\alpha_1 = -0.13 \text{ GeV}^{1/2}, \quad \alpha_2 = -0.36 \text{ GeV}^{1/2}.
\]  

(77)

That way, all parameters are defined.

For measured processes, the experimental and theoretical upper bounds of the exact BRs are compared in Table IIIa. For some interesting processes that have not been measured, the theoretical upper bounds are given in Table IIIb. In the both tables, the numerical part of the theoretical results is evaluated for degenerate heavy neutrino masses and the maximal heavy neutrino mass permitted by PUB, maximal \(s_L^0\) values and neglecting the \(B_{lN}\) phases. The factors \(x_{ll}, y_{ll}\) and \(y_{l'il_1'l_2}\) and \(z_{ll}\) describe the deviation of BRs from these values, when the model parameters assume other values. The factors \(y_{ll}\) and \(y_{l'il_1'l_2}\) give only the behavior of the dominant, \(m_N^2\)-dependent term, on the model parameters. For \(m_N\) values for which the terms quadratic in \(B_{lN}\) matrices begin to dominate \((m_N \sim 1000 - 1500 \text{ GeV})\), the \(z_{ll}\) terms begin to dominate.

Comparing the theoretical upper bounds for the processes of the same type with different leptons in the initial and final state, one can see that they are often comparable in magnitude. For instance, upper bounds for BRs of the processes \(l \to l'\gamma\), \(l \to l'l_1l_2\) and \(Z \to ll'\) are of the order \(\sim 10^8\), \(\sim 10^{-6}\) and \(\sim 10^{-6}\), respectively. For that reason, the muon LFV processes which have been measured with the greatest precision, are the most attractive for finding LFV. A process with weaker experimental bounds may be interesting only if the parameter(s) \(x_{ll}\) for that process is (are) large.

If, for a specific process, the theoretical upper bound is larger than the experimental one, then the process gives the better bound on a specific combination of \(B_{lN}\)-s than the limit (4). The processes for which this ratio is larger than one are \(\mu \to e\gamma\), \(\mu \to eee\), \(\mu Ti \to eTi\), \(\tau \to e\rho\), \(\tau \to e\pi^+\pi^-\) and \(Z \to e\tau\). For the last three processes the ratio is very close to one. As their amplitudes are dominated by \(m_N^2\) part of the amplitude, the new limits on \(B_{lN}\) combinatons contain \(m_N^2\) mass dependence, too, and therefore are uninteresting. For the first three processes the ratio is much larger than one, and they do give new limits on specific combinations of \(B_{lN}\)-s as shown in Ref. \([12]\). Since that paper was published, the limits on \(\mu \to e\gamma\) and \(\mu Ti \to eTi\) improved by factors 1.3 (4.1 \([85]\)) and 7, respectively. The first of them gives a new limit on nondiagonal \(\mu-e\) mixing,

\[
\sum_{i=1}^{n_G} B_{\mu N_i} B^*_{e N_i} \leq 2.15 \times 10^{-4} \ (1.19 \times 10^{-4}).
\]  

(78)

To obtain the limit on the nondiagonal \(\tau-e\) and \(\tau-\mu\) mixings, the present experimental sensitivities of \(\tau \to l\) decays should improve by two orders of magnitude. It is interesting that the \(\mu Ti \to eTi\) conversion also gives very good mass independent limit on the sum \(\sum_{i=1}^{n_G} B_{\mu N_i} B^*_{e N_i}\). Namely, \(\mu Ti \to eTi\) amplitude contains mass independent part coming from the photon exchange. If the terms in the \(\mu Ti \to eTi\) amplitude do not cancel completely, one can make an estimate of the sum by attributing the whole amplitude to the photon exchange part of the amplitude. That way one can only make a worse estimate of the sum. The limit one obtains that way reads
\[
\sum_{i=1}^{n_G} B_{\mu N_i} B_{e N_i}^{*} \leq 3.93 \times 10^{-4}.
\] (79)

For all processes whose amplitudes comprise only the box amplitude, the theoretical upper bounds are several orders of magnitude smaller than the experimental upper bounds. For the \( K_L \rightarrow e^+\mu^\pm \) decay the ratio of theoretical and experimental upper bound is largest, 1.58 \( \times 10^{-3} \). As the present experimental limit is 2 \( \times 10^{-11} \), its significant improvement cannot be expected. Although the experimental upper bounds for semileptonic LFV \( B \)-meson processes are weak, the corresponding theoretical upper bounds are of the order \( \sim 10^{-9} \). Therefore, \( B \)-meson decays are interesting for finding LFV decays in the near future.

The recent Super-Kamiokande experiment shows there is a large mixing between \( \nu_\mu \) and some other light neutrino, very probably \( \nu_\tau \). If the additional heavy neutrinos exist, this might suggest a large "angle" parameter \( x_{\mu\tau}^0 \). Therefore, the Super-Kamiokande result might be a sign to search for LFV among processes with tauon and muon in the final (and initial) state.

To estimate how large error one can make using the upper bound procedure from section III, the BRs for the processes \( \mu T i \rightarrow e T i, Z \rightarrow \mu^+\mu^\pm, K_L \rightarrow e^+\mu^\pm \) and \( B^- \rightarrow K^- \mu^+\mu^\pm \) are evaluated using both the upper bound procedure and the "realistic" \( B_{lN}-s \). These processes are chosen because they have the maximal BR within the group of processes with the same dominant composite loop function. The first two of these processes contain \( F_Z^{ll} \) function and the last two contain \( F_{box}^{ll} \) function only. The BRs are evaluated for degenerate heavy neutrino masses and two sets of \( s_L^a \) and \( x_W^0 \) parameters for which the maximal theoretical value for \( B(\mu T i \rightarrow e T i) \) is equal to the present experimental upper bound. The firts set is obtained from the "maximal set" \( s_L^a \) from Eq. 11 and all \( x_W = 0 \) by replacing the maximal value for \( (s_L^{ve})^2 \) with the value \( (s_L^{ve})^2 = 4.29 \times 10^{-10} = 7.1 \times 10^{-3} \times (2.459 \times 10^{-4})^2 \). The second set is obtained from the "maximal set" by putting \( x_{\mu e} = x_{\tau e} = 2.459 \times 10^{-4} \). The first set is used together with upper bound procedure and with "realistic" \( B_{lN} \) matrix elements. The second can be applied only within upper bound procedure, because the procedure with "realistic" \( B_{lN} \) matrix elements has fixed \( x_W^0 \) values. In all calculations \( x_{\mu\tau} \) is kept to be equal one in accord with the Super-Kamiokande results. The BRs are presented in Fig. 1. as functions of heavy neutrino mass. The figures illustrate the following properties of the BRs. First, for all \( m_N \) values, the upper bound procedure gives larger value than the "realistic" \( B_{lN}-s \). Second, while the BRs evaluated in the upper bound procedure increase in the whole region of \( m_N \) values permitted by PUB, the BRs evaluated with the "realistic" \( B_{lN}-s \) may have a maximum below the \( m_N^{PUB} \). The maximum is a consequence of the mass dependence of the "realistic" \( B_{lN}-s \). All BRs of processes with box-amplitude only have the maximum, but it can appear in the BRs having the \( Z \)-amplitude, too. Third, the by reduction of \( x_W^0 \) one obtains the result which are numerically equivalent to the results obtained by reduction of \( s_L^a \) parameters. Fourth, a strong cancelation of the amplitude terms may appear in the BRs evaluated with the "realistic" \( B_{lN}-s \), as in the case of \( \mu T i \rightarrow e T i \). Fifth, the error one can make in the evaluation of the maximum of BRs using the upper bound procedure is \( \lesssim 10 \) for processes with the box-amplitude only, and \( \lesssim 100 \) for processes with \( Z \)-amplitudes. The flat behavior of \( Z \rightarrow l^+l^- \) at \( m_N \sim 100 \text{ GeV} \) is a consequence of threshold effects.
As shown in the section III C, all heavy neutrino masses, except one, can assume any value between zero and infinity. BRs should not assume values larger than one in the whole parameter space permitted by the model. The illustration of convergence and of good behavior of branching ratios evaluated using the upper bound procedure and "realistic" $B_{1\nu}$-s is given in Fig. 2. Branching ratios are evaluated keeping two masses equal, while the third one is assumed to take very large variable values values. In Fig 2. the branching ratios for the same processes as in Fig 1. are given, but here as a function of ratio of the large mass $(m_{N_2})$ and mass which is kept constant $(m_{N_1} = m_{N_3})$. Graphs in Fig 2. show that the very heavy neutrinos decouple, and therefore, that the nondecoupling of heavy neutrinos is only a transient effect. For the upper bound procedure, the decoupling of the very heavy neutrino(s) manifests as the equality of BR values for degenerate heavy neutrinos and when some of masses tend to infinity, while for "realistic" $B_{1\nu}$-s BR-s reduce in magnitude. Figure 2 also illustrates that the upper bound procedure is very crude in the transient region where the upper bounds (15) and upper bound (14) are almost equally effective as the second (13) bound. To show that with the proper choice of the parameters experimental limits are always satisfied, in the first panel of Fig. 2 the additional BR curve is added, evaluated in the upper bound procedure for parameters for which the maximal BR value is smaller than the present experimental upper bound for $R(\mu Ti \to eTi)$. Only top of the curve is seen in the figure. The curves obtained using the "realistic" $B_{1\nu}$-s are much smoother than the curves following from the upper bound procedure. Therefore, for nondegenerate heavy neutrinos good knowledge of the $B_{1\nu}$ matrix elements is necessary to obtain reasonable estimate of the BR values.

VI. CONCLUSIONS

All low energy neutrinoless LFV processes are studied in an extension of SM by heavy $SU(2)_L \times U(1)$ singlet Dirac neutrinos. The structure of amplitudes and relations between BRs are carefully analized. It is shown that, in principle, the neutrinoless LFV decays cannot give new limits on the "diagonal" mixings $s^\nu_{1L}$. The approximative expressions for all BRs are listed, keeping only the dominant terms of the corresponding amplitudes in the large heavy-neutrino mass limit. The approximative BRs are compared within the groups of processes with the same dominant composite loop function, and within each group the experimentally most interesting process are found: $\mu Ti \to eTi$, $Z \rightarrow \tau^\mp l^\pm$, $K_L \rightarrow e^\mp \mu^\pm$, $B^- \rightarrow K^{*-} \mu^\pm e^\pm$, $\tau \rightarrow e\pi^+K^-$ and $B^- \rightarrow K^{*-} \tau^\mp e^\pm$. The upper bounds of exact BRs are evaluated using the improved version of the upper bound procedure found in the previous publication [10]. The results are compared with present experimental upper bounds. For maximal values of model parameters, only six processes have the theoretical upper bounds larger than the experimental ones: $\mu \rightarrow e\gamma$, $\mu \rightarrow eee$, $\mu Ti \to eTi$, $\tau \rightarrow e\rho^0$, $\tau \rightarrow e\pi^+\pi^-$ and $Z \rightarrow e\tau$. For these processes new limits on combinations of $B_{1\nu}$ matrices are obtained. The first three have been studied before [12] and they give a new limit on the nondiagonal $\mu-e$ mixing. The limit is updated here. For the last three, the ratio of the theoretical and experimental upper bounds are very close to one and the obtained limit is mass dependent. Therefore, it is not useful. Two orders of magnitude improvement of experimental sensitivities is needed to obtain mass independent limits on the nondiagonal $\tau-e$ and $\tau-\mu$ mixings from $\tau \rightarrow l\gamma$ decays. Concerning the processes with the box-amplitude only, the $K_L \to e^\mp \mu^\pm$ decay has the best
ratio of theoretical to experimental upper bound. Nevertheless, neutrinoless LFV $B$-meson decays have BRs of the order $\sim 10^{-9}$, what makes them interesting for finding LFV in future experiments. If the structure of the massless part of the $B$ matrix is as suggested by the Super-Kamiokande experiment, one may expect that in the future the processes containing $\tau$ and $\mu$ leptons in the final (and initial) state will be most interesting for finding LFV. Besides BRs for the low-energy neutrinoless LFV decays, the constant characteristic for the muonium–antimuonium conversion $G_{M\bar{M}}$ is evaluated. The result obtained is too small to be interesting experimentally.

All above results depend only on the gauge structure of the model used and masses of heavy neutrinos. The results do not change if the massless neutrinos are replaced with the light neutrinos satisfying present experimental limits. A comment on extraction of heavy neutrino mixings from astrophysical observations is given. Following the $V$-model assumption of massless ”light” neutrinos, an analysis of oscillations of three massless neutrinos in the supernovae is done. The analysis gives the limits on mixings in the massless neutrino sector that are in a slight contradiction with the Super-Kamiokande results.

ACKNOWLEDGEMENTS. Part of this work was presented on the TAU '98 Workshop at Santander, Spain. I am indebted to K.K. Gan who promoted my participation at the workshop, to all members of the organizing committee of the workshop, and especially to A. Pich and A. Ruiz who invited me to the workshop. Very pleasant atmosphere, stimulating discussions with K.K. Gan, R. Stroynowski and many other colleagues at the workshop stimulated the present investigation. I am indebted to R. Horvat for many instructive discussions on neutrino oscillations and supernovae. I kindly thank S. Fajfer for giving me the best values for ”CHPT+HQET” parameters needed for neutrinoless LFV decays of heavy meson. This work is supported by project 1-03-233 ”Field theory and structure of elementary particles”.

APPENDIX A:

The form factors $a_P$ and $b_P$ and $a_V$, $b_V$, $c_V$ and $d_V$ follow directly from matrix elements of corresponding hadronic currents (26). They read

\[ a_P = -\frac{f_H}{f_P} - 2g \frac{f_{H^*}}{f_P} \frac{m_{H^*}^2}{m_{H^*}^2} \frac{p_2 \cdot q}{m_2^2} \frac{(m_1^2 m_{H^*}^2)^{1/2}}{q^2 - m_{H^*}^2}, \]

\[ b_P = 2g \frac{f_{H^*}}{f_P} \left(1 + \frac{p_2 \cdot q}{m_{H^*}^2} \right) \frac{(m_1^2 m_{H^*}^2)^{1/2}}{q^2 - m_{H^*}^2}, \] \hspace{1cm} (A1)

and

\[ a_V = 2^{3/2} \lambda g_V f_H \frac{(m_{H^*}^2 m_{H^*}^{-1})^{1/2}}{q^2 - m_{H^*}^2}, \]

\[ b_V = -2^{1/2} \beta g_V f_H \frac{(m_{H^*}^2 m_{H^*}^{-1})^{1/2}}{q^2 - m_{H^*}^2}, \]

\[ c_V = -2^{1/2} \alpha_1 g_V (m_{H^*}^2)^{1/2}, \]

\[ d_V = 2^{1/2} \alpha_2 \frac{(m_{H^*}^2)^{1/2}}{m_1^2}. \] \hspace{1cm} (A2)
The phase functions $Z_{P_i}$, $i = 1, 2, 3$ and $Z_{V_i}$, $i = 1, \cdots, 8$ in the square bracket expressions in (27) read

$$Z_{P1} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ 2p_1 \cdot p_3 p_1 \cdot p_4 - m_1^2 p_3 \cdot p_4 \right],$$

$$Z_{P2} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ 2(p_1 \cdot p_3 p_2 \cdot p_4 + p_1 \cdot p_4 p_2 \cdot p_3 - p_1 \cdot p_2 p_3 \cdot p_4) \right],$$

$$Z_{P3} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ 2p_2 \cdot p_3 p_2 \cdot p_4 - m_2^2 p_3 \cdot p_4 \right],$$

(A3)

for $\mathcal{H} \rightarrow Pll'$ decays and

$$Z_{V1} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ p_1 \cdot p_3 p_1 \cdot p_2 p_2 \cdot p_4 + p_2 \cdot p_3 p_1 \cdot p_4 p_1 \cdot p_2 - m_1^2 p_2 \cdot p_3 p_2 \cdot p_4 - m_2^2 p_1 \cdot p_3 p_1 \cdot p_4 \right],$$

$$Z_{V2} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ -q^2 p_3 \cdot q p_4 \cdot q + \frac{1}{2} q^2 p_3 \cdot p_4 + \frac{1}{m_2^2} (p_2 \cdot q)^2 \left( p_3 \cdot q p_4 \cdot q - \frac{1}{2} q^2 p_3 \cdot p_4 \right) \right],$$

$$Z_{V3} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ p_3 \cdot p_4 + \frac{1}{m_2^2} (p_2 \cdot p_3 p_2 \cdot p_4 - \frac{1}{2} m_2^2 p_3 \cdot p_4) \right],$$

$$Z_{V4} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ -q^2 p_1 \cdot p_3 p_1 \cdot p_4 + \frac{1}{2} m_1^2 q^2 p_3 \cdot p_4 + \frac{1}{m_2^2} (p_2 \cdot q)^2 \left( p_1 \cdot p_3 p_1 \cdot p_4 - \frac{1}{2} m_2^2 p_3 \cdot p_4 \right) \right],$$

$$Z_{V5} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ 2p_1 \cdot p_3 p_2 \cdot p_4 - 2p_1 \cdot p_4 p_2 \cdot p_3 \right],$$

$$Z_{V6} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ -2 p_3 \cdot q p_4 \cdot q + q^2 p_3 \cdot p_4 + \frac{1}{m_2^2} p_2 \cdot q (p_2 \cdot p_3 p_4 \cdot q + p_2 \cdot p_4 p_3 \cdot q - p_3 \cdot p_4 p_2 \cdot q) \right],$$

$$Z_{V7} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ -q^2 p_3 \cdot q p_1 \cdot p_4 - q^2 p_4 \cdot q p_1 \cdot p_3 + q^2 p_1 \cdot q p_3 \cdot p_4 + \frac{1}{m_2^2} (p_2 \cdot q)^2 \left( p_3 \cdot q p_1 \cdot p_4 + p_4 \cdot q p_1 \cdot p_3 - p_1 \cdot q p_3 \cdot p_4 \right) \right],$$

$$Z_{V8} = \int_{s_{13}^{\min}}^{s_{13}^{\max}} ds_{13} \left[ -p_3 \cdot q p_1 \cdot p_4 - p_4 \cdot q p_1 \cdot p_3 + p_1 \cdot q p_3 \cdot p_4 + \frac{1}{m_2^2} p_2 \cdot q (p_2 \cdot p_3 p_1 \cdot p_4 + p_2 \cdot p_4 p_1 \cdot p_3 - p_1 \cdot p_2 p_3 \cdot p_4) \right],$$

(A4)

for $\mathcal{H} \rightarrow Vll'$ decays. The $p_1$, $p_2$, $p_3$ and $p_4$ are 4-momenta of a heavy meson ($\mathcal{H}$), a light meson ($P$ of $V$), a lepton ($l$) and antilepton ($l'$), respectively. The corresponding masses are $m_1$, $m_2$, $m_3$ and $m_4$. The phase functions contain integration over Mandelstam variable $s_{13} = (p_1 - p_3)$. The limits of integration are defined in the standard way [30].

Table I. List of neutrinoless LFV processes, the composite loop functions and the tree level functions contributing to them and the approximations (physics) needed for evaluation of amplitudes. $l$, $P$, $V$, $H$ and $B$ denote leptons, light pseudoscalar mesons, light vector mesons, heavy pseudoscalar mesons (containing $c$ or $b$ quark), and light baryons, respectively. In the first column the list of the neutrinoless LFV processes is given, with references only to the calculations made within extensions of SM with heavy neutrinos. The abbreviations cqf = conserved quark flavor, ncqf = nonconserved quark flavor and $H = H$iggs mediated process, serve to distinguish processes with seemingly similar particle content. In the second column, the Feynman diagrams contributing to any specific process are listed. For instance, $l\rightarrow q\rightarrow box$ corresponds to the box diagram with one lepton current and one quark current. In the third column the approximations and physics used for calculation of amplitudes are listed. Following abbreviations are used: HQET = heavy quark effective theory, CHPT = chiral perturbation theory, VMD = vector meson dominance, GTR = Goldberger-Treiman relation, $l$ = lepton physics, $q$ = quark physics.
Table IIa. Coefficients defining the meson content in axial-vector quark currents with denoted quark content and normalization given by Eq. (61). Two additional coefficients are different from zero: $\alpha_{box,ds}^{K_0} = 1$ and $\alpha_{box,sd}^{\bar{K}_0} = 1$.

| $P^0$ | $\alpha_{P^0}$ | $\alpha_{box,uu}^{P^0}$ | $\alpha_{box,dd}^{P^0}$ | $\alpha_{box,ss}^{P^0}$ | $\alpha_{P^0}$ |
|-------|----------------|--------------------------|--------------------------|--------------------------|----------------|
| $\pi^0$ | $-\sqrt{2}$ | $-\frac{1}{\sqrt{2}}$ | $-\frac{1}{\sqrt{2}}$ | 0 | |
| $\eta$ | $-\sqrt{2}p - s$ | $-\frac{cp}{\sqrt{6}} + \frac{sp}{\sqrt{3}}$ | $\frac{cp}{\sqrt{6}}$ | $-\frac{cp}{\sqrt{3}} - \frac{sp}{\sqrt{3}}$ | |
| $\eta'$ | $\frac{cp}{\sqrt{3}} - \sqrt{2}p - s$ | $-\frac{cp}{\sqrt{6}} - \frac{sp}{\sqrt{3}}$ | $\frac{cp}{\sqrt{6}} + \frac{sp}{\sqrt{3}}$ | $-\frac{cp}{\sqrt{3}} - \frac{sp}{\sqrt{3}}$ | |

Table IIb. Coefficients defining the meson content in vector quark currents with denoted quark content and normalization given in Eq. (61). Two additional coefficients are different from zero: $\alpha_{box,ds}^{K^0} = -1$ and $\alpha_{box,sd}^{\bar{K}^0} = -1$.

| $V^0$ | $\alpha_{V^0}$ | $\alpha_{box,uu}^{V^0}$ | $\alpha_{box,dd}^{V^0}$ | $\alpha_{box,ss}^{V^0}$ | $\beta_{V^0}^\gamma$ | $\gamma_{V^0}^\gamma$ |
|-------|----------------|--------------------------|--------------------------|--------------------------|----------------|----------------|
| $\rho^0$ | $\sqrt{2}cw$ | $-\frac{1}{\sqrt{2}}$ | $-\frac{1}{\sqrt{2}}$ | 0 | $2\sqrt{2}sw^2$ | $-2\sqrt{2}sw^2$ |
| $\phi$ | $\frac{cv}{\sqrt{3}} + \frac{sv}{\sqrt{3}}$ | $\frac{cv}{\sqrt{6}} - \frac{sv}{\sqrt{3}}$ | $\frac{cv}{\sqrt{6}} + \frac{sv}{\sqrt{3}}$ | $\frac{cv}{\sqrt{3}} + \frac{sv}{\sqrt{3}}$ | $2\sqrt{2}sv\eta_{V^0}$ | $2\sqrt{2}sv\eta_{V^0}$ |
| $\omega$ | $-\frac{cv}{\sqrt{3}} + \frac{sv}{\sqrt{3}}$ | $\frac{cv}{\sqrt{6}} + \frac{sv}{\sqrt{3}}$ | $-\frac{cv}{\sqrt{6}} + \frac{sv}{\sqrt{3}}$ | $\frac{cv}{\sqrt{3}} + \frac{sv}{\sqrt{3}}$ | $2\sqrt{2}sv\eta_{V^0}$ | $2\sqrt{2}sv\eta_{V^0}$ |
Table IIIa. The comparison of experimental and theoretical upper bounds on LFV BRs. Experimental upper bounds for unmarked processes are taken from Ref. [36], while those denoted by # are from Ref. [37]. The newest value $B^{UB}(\mu^- \rightarrow e^-\gamma) = 1.2 \times 10^{-11}$ is given in Ref. [86].
| Process | $B_{\text{exp}}^{\mu}$ | $B_{\text{th}}^{\mu}$ |
|---------|-----------------|-----------------|
| $\mu^- \to e^-\gamma$ | $3.8 \times 10^{-11}$ | $8.08 \times 10^{-9} y_{\mu e}^{\gamma}$ |
| $\tau^- \to e^-\gamma$ | $2.7 \times 10^{-6}$ | $3.38 \times 10^{-8} y_{\tau e}^{\gamma}$ |
| $\tau^- \to \mu^-\gamma$ | $3.0 \times 10^{-6}$ | $6.68 \times 10^{-8} y_{\tau \mu}^{\gamma}$ |
| $\mu^- \to e^-e^+e^-$ | $1.0 \times 10^{-12}$ | $6.41 \times 10^{-7} y_{\mu e}^{e^+e^-}$ |
| $\tau^- \to e^-e^+e^-$ | $2.9 \times 10^{-6}$ | $2.69 \times 10^{-6} y_{\tau e}^{e^+e^-}$ |
| $\tau^- \to \mu^-\mu^+\mu^-$ | $1.9 \times 10^{-6}$ | $4.48 \times 10^{-7} y_{\tau \mu}^{\mu^+\mu^-}$ |
| $\tau^- \to e^-\mu^+\mu^-$ | $1.8 \times 10^{-6}$ | $1.44 \times 10^{-6} y_{\tau e}^{\mu^+\mu^-}$ |
| $\tau^- \to \mu^-e^+e^-$ | $1.7 \times 10^{-6}$ | $3.71 \times 10^{-7} y_{\tau \mu}^{e^+e^-}$ |
| $\tau^- \to e^+\mu^-\mu^-$ | $1.5 \times 10^{-6}$ | $1.32 \times 10^{-9} y_{\tau \mu}^{\mu^-\mu^+}$ |
| $\tau^- \to \mu^+e^-e^-$ | $1.5 \times 10^{-6}$ | $6.67 \times 10^{-9} y_{\tau e}^{e^-e^+}$ |
| $\tau^- \to e^-\pi^0$ | $3.7 \times 10^{-6}$ | $2.77 \times 10^{-7} y_{\tau e}^{\pi^0}$ |
| $\tau^- \to \mu^-\pi^0$ | $4.0 \times 10^{-6}$ | $5.40 \times 10^{-7} y_{\tau \mu}^{\pi^0}$ |
| $\tau^- \to e^-\eta$ | $8.2 \times 10^{-6}$ | $4.01 \times 10^{-7} y_{\tau e}^{\eta}$ |
| $\tau^- \to \mu^-\eta$ | $9.6 \times 10^{-6}$ | $7.81 \times 10^{-8} y_{\tau \mu}^{\eta}$ |
| $\tau^- \to e^-\rho^0$ | $2.0 \times 10^{-6}$ | $2.70 \times 10^{-6} y_{\tau e}^{\rho^0}$ |
| $\tau^- \to \mu^-\rho^0$ | $6.3 \times 10^{-6}$ | $5.27 \times 10^{-7} y_{\tau \mu}^{\rho^0}$ |
| $\tau^- \to e^-\phi$ | $6.9 \times 10^{-6}$ | $2.30 \times 10^{-6} y_{\tau e}^{\phi}$ |
| $\tau^- \to \mu^-\phi$ | $7.0 \times 10^{-6}$ | $4.46 \times 10^{-7} y_{\tau \mu}^{\phi}$ |
| $\tau^- \to e^-\pi^+\pi^-$ | $2.2 \times 10^{-6}$ | $2.67 \times 10^{-7} y_{\tau e}^{\pi^+\pi^-}$ |
| $\tau^- \to \mu^-\pi^+\pi^-$ | $8.2 \times 10^{-6}$ | $5.19 \times 10^{-7} y_{\tau \mu}^{\pi^+\pi^-}$ |
| $\tau^- \to e^-K^+K^-$ | $6.0 \times 10^{-6}$ | $1.07 \times 10^{-6} y_{\tau e}^{K^+K^-}$ |
| $\tau^- \to \mu^-K^+K^-$ | $15 \times 10^{-6}$ | $2.07 \times 10^{-7} y_{\tau \mu}^{K^+K^-}$ |
| $\pi^0 \to e^-\mu^+$ | $1.72 \times 10^{-8}$ | $5.54 \times 10^{-15} y_{\mu e}^{\pi^0}$ |
| $\eta \to e^-\mu^+$ | $6 \times 10^{-6}$ | $1.61 \times 10^{-16} y_{\mu e}^{\eta}$ |
| $Z \to e^+\mu^\pm$ | $1.7 \times 10^{-6}$ | $3.43 \times 10^{-7} y_{\mu e}^{\pm}$ |
| $^\# Z \to e^+\tau^\pm$ | $7.3 \times 10^{-6}$ | $8.08 \times 10^{-6} y_{\tau e}^{\pm}$ |
| $^\# Z \to \mu^+\tau^\pm$ | $1.0 \times 10^{-6}$ | $1.59 \times 10^{-6} y_{\tau \mu}^{\pm}$ |

| Process | $B_{\text{exp}}^{T^{-}}$ | $B_{\text{th}}^{T^{-}}$ |
|---------|-----------------|-----------------|

| $B^0 \to K^*0 \mu^+ \tau^\pm$ | $3.60 \times 10^{-10} z_{\tau\mu}$ |
| $B^0 \phi e^+ \mu^\pm$ | $1.01 \times 10^{-10} z_{\mu\mu}$ |
| $\bar{B}^0 \phi e^+ \tau^\pm$ | $1.56 \times 10^{-9} z_{\tau\mu}$ |
| $B^0 \phi \mu^+ \tau^\pm$ | $3.06 \times 10^{-10} z_{\tau\mu}$ |
| $\Sigma^+ \to p e^+ \mu^\pm$ | $4.09 \times 10^{-18} z_{\mu\mu}$ |
| $\Lambda \to n e^+ \mu^\pm$ | $2.74 \times 10^{-18} z_{\mu\mu}$ |
| $\Xi^0 \to \Lambda e^+ \mu^\pm$ | $3.18 \times 10^{-18} z_{\mu\mu}$ |
| $\Xi^0 \to \Sigma^0 e^+ \mu^\pm$ | $1.29 \times 10^{-20} z_{\mu\mu}$ |
| $\Xi^- \to \Sigma^- e^+ \mu^\pm$ | $2.02 \times 10^{-20} z_{\mu\mu}$ |
| $\Sigma^0 \to n e^+ \mu^\pm$ | $1.99 \times 10^{-27} z_{\mu\mu}$ |
FIGURES

FIG. 1. The BRs and the upper bounds of the BRs for four leading processes of the groups of processes given in equations (64), (65), (66) and (71). Each of these four processes is shown in one of four panels. The BRs are evaluated for degenerate heavy neutrino masses, $m_N$. The model parameters are adjusted so that the maximal BR values are smaller than the present experimental upper bounds. It is assumed that the "angle" parameter $x_{\mu\tau} \approx 1$, in accord with the Super-Kamiokande measurements. The full line represents the upper bound calculation keeping the parameters $x_{ll'}$ equal to one, and adjusting the $s_{\nu L}^\nu$ parameters: $(s_{e L}^{\nu e})^2 = 4.29 \times 10^{-10}$, $(s_{\mu L}^{\nu \mu})^2 = 1.4 \times 10^{-3}$, and $(s_{\tau L}^{\nu \tau})^2 = 3.3 \times 10^{-2}$. The heavy long-dashed line represents the upper bound calculation keeping the $s_{\nu L}^\nu$ equal to the present experimental upper bound values (4), and adjusting the $x_{ll'}$ parameters: $x_{\mu e} = x_{\tau e} = 2.459 \times 10^{-4}$, $x_{\tau \mu} = 1$. The dotted line represents the calculation with the "realistic" $B_{1N}$ matrix elements, and with the same parameters as for the full line calculation.

FIG. 2. The BRs and upper bounds for BRs for the same processes as in Fig 1., but now evaluated as a function of the ratio of two heavy neutrino masses, $m_{N_2}/m_{N_1}$. For all curves the first and third masses are taken to be degenerate, $m_{N_1} = m_{N_3} = 4000 \text{ GeV}$, while the second mass assumes values within the interval $1 \leq m_{N_2}/m_{N_1} \leq 10^5$. The types of lines represent the same sets of parameters as in Fig. 1. In the first panel, representing the $\mu \rightarrow e$ conversion on $Ti$, additional curve is added, to show that one can always achieve theoretical values smaller than the present experimental bounds. The calculation for that curve was made within the upper bound procedure, for $x_{ll'} = 1$, $(s_{e L}^{\nu e})^2 = (s_{\mu L}^{\nu \mu})^2 = 5.0 \times 10^{-10}$ and $(s_{\tau L}^{\nu \tau})^2 = 0.033$.
