Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Nowhere to hide: The significant impact of coronavirus disease 2019 (COVID-19) measures on elite and semi-elite South African athletes

Lockdown impact

ABSTRACT

Objectives: To describe the perceptions of South African elite and semi-elite athletes on return to sport (RTS); maintenance of physical conditioning and other activities; sleep; nutrition; mental health; healthcare access; and knowledge of coronavirus disease 2019 (COVID-19).

Design: Cross-sectional study.

Methods: A Google Forms survey was distributed to athletes from 15 sports in the final phase (last week of April 2020) of the level 5 lockdown period. Descriptive statistics were used to describe player demographic data. Chi-squared tests investigated significance (p < 0.05) between observed and expected values and explored sex differences. Post hoc tests with a Bonferroni adjustment were included where applicable.

Results: 67% of the 692 respondents were males. The majority (56%) expected RTS after 1–6 months. Most athletes trained alone (61%; p < 0.0001), daily (61%; p < 0.0001) at moderate intensity (58%; p < 0.0001) and for 30–60 min (72%). During leisure time athletes preferred sedentary above active behaviour (p < 0.0001). Sleep patterns changed significantly (79%; p < 0.0001). A significant number of athletes consumed excessive amounts of carbohydrates (76%; p < 0.0001; males 73%; females 80%). Many athletes felt depressed (52%), and required motivation to keep active (55%). Most had access to healthcare during lockdown (80%) and knew proceedings when expecting COVID-19 (92%).

Conclusions: COVID-19 had physical, nutritional and psychological consequences that may impact on the safe RTS and general health of athletes. Lost opportunities and uncertain financial and sporting futures may have significant effects on athletes and the sports industry. Government and sporting federations must support athletes and develop and implement guidelines to reduce the risk in a COVID-19 environment.

Practical implications

1. Implement a culture of education for athletes and support staff regarding hygiene, wearing masks, social distancing measures and self-isolation to improve health literacy and promote required behaviours.
2. Consider health, nutritional and psychological support and education during the remainder of the lockdown period.
3. Reduce the injury risk by implementing a progressive training load and allowing for maximum adaptation before competition is re-introduced.
4. Sleep hygiene and its effects on performance should become an imperative part of athletic education.
5. Athletes returning to sport should require thorough medical assessment including nutrition assessment prior to resumption of high intensity sporting activity.
6. Mental health aspects form an important part of athlete performance and should be recognised and acted on timely through life/performance coaches or psychologists.
7. Stimulate athletes to become saving and investment-wise, and plan their future in time for a career/business/life after sport.

1. Introduction

The coronavirus disease 2019 (COVID-19) caused by the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) resulted in a global pandemic with unprecedented consequences. Many scientific articles (peer-reviewed and non-peer reviewed) have been published regarding epidemiology, pathogenesis, complications and treatment. The COVID-19 pandemic forced governments to implement unparalleled measures to curb the rapid spread of the disease including strict lockdown, banning of all organised and social gatherings (including sports events) and restricting non-essential travel, with a significant effect on the sports industry and athletes. In South Africa, level 5 lockdown measures were enforced from 26 March to 30 April (5 weeks). Only essential services, travel and shopping were allowed and exercise outside individual property boundaries was not allowed, likely having a psychological impact on all, including athletes. Our current understanding of these lockdown measures on training, nutrition and mental health of athletes are limited. This study aims to investigate the perceptions of South African elite and semi-elite athletes on (1) return to sport (RTS); (2) maintenance of physical conditioning and other activities; (3) sleep; (4) nutrition; (5) mental health; (6) healthcare access; and (7) knowledge of the COVID-19 disease.

2. Methods

A cross-sectional study was designed, based on input from researchers and clinicians looking after athletes, regarding the challenges they experienced during the lockdown period. Survey questions were adapted from validated questionnaires on maintenance of activity, nutrition and mental state. The survey was piloted by 20 healthcare workers including sports physicians, physiotherapists and biokineticists. Following ethics approval from the Ethical Committee of the University of Pretoria (REC 274/2020), a link to the online Google Form survey was distributed to a convenience sample of athletes via WhatsApp. Athletes were asked to read the description and need for the study and click on the link to proceed after giving consent. Participants from 15 sports (soccer, hockey, rugby, cricket, athletics, netball, basketball, endurance running, cycling, track and field, swimming, squash, golf, tennis, karate) were recruited through the databases of the researchers, sports medicine healthcare professionals and administrators affiliated with the research team. The inclusion criteria was (1) elite and semi-elite athletes based in South Africa, (2) >18 years of age. Recreational athletes were excluded. The survey was live for 72 hours during the level 5 lockdown period, from 28 April to 30 April 2020 and took 10–15 min to complete. Data were collected from Google Forms and exported to a csv file for data analysis. The data consisted of categorical feedback, hence the descriptive statistics consisted of frequencies and percentages which described the feedback received. We used the Chi-square goodness of fit test to investigate if a significant difference, tested at a 5% level of significance, existed between the observed and expected values. The Chi-square test of independence was used to explore sex specific associations. Post hoc analyses were included with a Bonferroni adjustment where applicable. As questions were single or multiple choice options. It should be noted that proportions do not add up to 100% for the questions with multiple responses. Multiple choice options on risk reduction behaviour were listed as per the World Health Organization (WHO) and National Institute for Communicable Diseases (NICD) documents regarding the most important aspects.

3. Results

From a total of 1080 distributed surveys, 692 athletes responded. The response rate was 64% and respondents consisted of 67% males (Table 1). Some (presumably university level semi-elite athletes, n = 55; 8%) reported participation in two or more sports. Four respondents preferred not to reveal their sex.

Most respondents were from soccer (26%), followed by hockey (16%) and rugby (13%). Most males participated in soccer (37%), while most females played netball (31%).

Regarding return to competitive sport, 35% athletes expected RTS within 1–3 months whilst 31% felt unsure, and no sex difference was observed (p = 0.0740). Only 50% athletes were comfortable with RTS when allowed by authorities, and results are comparable between males and females (p = 0.6901). The athletes are willing to compete behind closed doors (p < 0.0001), while male athletes are more willing than females (p < 0.0001) (Table 2).

For exercise maintenance and other activities, more athletes trained alone (p < 0.0001), compared to those training alone but digitally directed by a trainer, or a medical person or using technology like Zoom together with other athletes. More males used Zoom to train with other athletes than females (p < 0.0001). Most athletes trained daily vs alternative days or ≤3× a week (p = 0.0001). More males trained daily compared to females (p = 0.0059). Sessions consisted mainly of own body weight (males 73%) and cardio exercises (females 70%). Athletes could train outside without breaking the law (p < 0.0001) (male vs female p = 0.3779), at a reduced training intensity (p < 0.0001) (male vs female p = 0.6972) and sessions lasted mostly 30–60 min (males vs females p = 0.6351). Sports specific equipment is used significantly more (p < 0.0001) than treadmills, steppers, stationary bikes, swimming. Males and females had comparable results (p = 0.0899). Sedentary behaviour above active behaviour was preferred during leisure time (p < 0.0001). Sedentary behaviour largely favoured watching television, and males significantly favoured electronic gaming compared to females (p < 0.0001) (Table 3).

More athletes reported changes in sleep-wake times during the lockdown period (p < 0.0001), but they still experienced restful sleep (p < 0.0001) and did not experience constant fatigue (p < 0.0001). There were no sex differences in sleep-wake times (p = 0.6045) and restful sleep (p = 0.2455), however, a significantly larger proportion of females felt more fatigued than males (p = 0.0213) (Table 4).

Even though not statistically significant, more than half of the athletes admitted to the worsening of their diet (p = 0.1486), with females significantly more than males (p < 0.0001). Excessive carbohydrate consumption was significantly more (p < 0.0001) than excessive fizzy drinks, poor hydration during and after exercise, processed foods, and red meat (Table 4).

Observing mental state, 52% of the athletes felt depressed at some time (p = 0.3230), and females reported a significantly (p < 0.0001) higher rate. While 54% of all athletes did not report energy loss, and 55% struggled to keep motivated; female athletes reported higher energy loss (p = 0.0084) and lack of motivation (p = 0.0358) compared to males. Most felt they adapted to the new routine (males vs females p = 0.0765). Libido stayed the same for most respondents, but significantly more males reported increased libido compared to females (p < 0.0001). Many athletes were not aware of online psychological and mental health programmes, however, females are significantly more mindful (p = 0.0020) (Table 4).

A significant number of athletes had access to healthcare (p < 0.0001; males vs females p = 0.5934). Both males and females accessed telehealth opposed to physical consultations (p < 0.0001), via WhatsApp (65% males vs 52% females) or telephone (60% males vs 56% female). More athletes had access to general practitioner-
ers and physiotherapists for medical assistance compared to other healthcare professionals ($p < 0.0001$). Males and females differed significantly towards choice of health access ($p < 0.0001$) (Table 5).

Television news, news websites, social media and government sites were the sources of knowledge on COVID-19 used as opposed to radio, friends, doctors, community forums, physiotherapists and bankers ($p < 0.0001$) and no sex difference was observed. Hand-washing with soap and water and hand sanitising with $>70\%$ alcohol content were rated as the most important ($p < 0.0001$; males vs females $p = 0.8127$). Most athletes were aware that shortness of breath, fever, dry cough and sore throat were the main symptoms of COVID-19 ($p < 0.0001$; males vs females $p = 0.8402$). Shortness of breath was identified by $85\%$ male vs $78\%$ female athletes as the main symptom of COVID-19. Most athletes knew how to proceed on symptom development ($p < 0.0001$; males vs females $p = 1.000$). On suspicion of COVID-19 symptoms, a significant difference existed in accessing healthcare via contacting their doctors, or opting for contacting the National Institute of Communicable Diseases (NICD) hotline, as opposed to going to a laboratory for testing, searching the web or social media or going to the doctor’s rooms ($p < 0.0001$). Both males and females knew proceedings ($p = 1.000$), and would contact a doctor (Table 5).

4. Discussion

The COVID-19 pandemic lockdown measures significantly impacted elite and semi-elite athletes in South Africa. One of our key findings is that despite high levels of uncertainty regarding RTS guidelines, most athletes are continuing to train daily. Two out of three athletes trained alone with only a minority of athletes using digital guidance by a professional. There are certain risks to unsupervised training, including an inadvertent lapse into poor technique and posture, which may predispose athletes to injuries. Solo training and a lack of sport-specific training may also be challenging for athletes who participate in team and very technical (e.g. pole vault) sports. More than half of the athletes were training at a moderate exercise intensity for 30–60 min per day, at a lower training load than normal. Moderate training loads allow for recovery and this is important during the COVID-19 pandemic to avoid blunting of the immune system. Even though the additional recovery time came at an opportune time (e.g. Olympics was 4 months away), deconditioning is bound to occur, posing challenges in reconditioning and safe RTS. The majority of athletes engaged in own bodyweight strength training, cardio workouts, and functional sport-specific training, resembling appropriate active rest phase modalities. Only a small number of athletes included proprioception in their programmes. Good proprioception plays an important role in accurate movement patterns and can prevent injuries and recurrence of injuries. Such exercises are easy to do indoors and even in confined spaces, and should be recommended. Athletes had considerable access to equipment, including sports specific equipment, treadmills, stoppers, free weights, swimming pools and stationary bikes, providing good opportunities for cross-training, which we also recommend to assist with whole-body maintenance and to add variety.

Leisure time activities with possible lifestyle changes during lockdown were of concern. The majority chose sedentary behaviour, especially watching television. Males engaged more in electronic and cell-phone gaming, possibly contributing to sleep alteration and feelings of fatigue. Few partook in alcohol-related activities during this period. The detrimental effects of sedentary behaviour on both physical and mental health is beyond dispute. Realistic changes to decrease sedentary behaviour during the lockdown needs to be advocated by health care professionals. Athletes are also exposed to the negative psychological consequences of COVID-19 like anxiety and stress reported across the wider society, where people are overwhelmed by the constantly changing alerts and media reports about the virus spread. Home confinement not only affect the physiological status of athletes, but the inability to compete may also influence athlete mental health. We found that one in two athletes was depressed, with energy loss and lack of motivation to train. Females are more affected in all these spheres, with potentially profound adverse effects on their mental health. A recent consensus document on athlete mental health stressed the importance of mental well-being for optimal performance. Access to psychological support to maintain their mental health during and after lockdown is paramount. A significant proportion of athletes reported a change in sleep routine, even though still restful. Nevertheless, almost half of the respondents reported feeling chronically fatigued. Quality and quantity of sleep have a significant impact on injury incidence and recovery post-exercise. Sleep allows for the immune system to regenerate and recuperate. Compromised immunity increases the risk of viral illness (including COVID-19), this is particularly important given the imminent winter of the southern hemisphere. Social isolation, exercise reduction, sedentary behaviour, and changes in nutrition have a psychological consequence and can impact sleep and fatigue. Athletes need to be

Respondents $n = 692$: completed responses received back. Responses $n = 769$: athletes reported participation in two or more sports.
educated regarding the psychological impact on sleep and fatigue and re-adjust their sleeping patterns on RTS.

More than half of the athletes reported deterioration in eating habits, especially a significant increase in carbohydrate ingestion. Impaired nutrition may result in a myriad of issues upon RTS including deteriorated performance, lifestyle-related concerns and affecting weight category sport. Athletes are generally believed to consume substantial amounts of supplements, but a large percentage of athletes in our study did not consume supplements. Only one in three athletes used a combination of vitamin C, multivitamins, zinc, vitamin B, protein and other unclassifiable supplements. During the COVID-19 pandemic some authors have advised taking supplements including vitamin C, zinc and vitamin D for immune enhancement. Most athletes can train outside without breaking regulations, exposing them to natural light to allow vitamin D synthesis. Given the significant inadequacies in nutrition during the lockdown, it seems appropriate to implement nutritional guidance by a sports nutritionist, both during the lockdown and afterward.

The majority of athletes had access to healthcare professionals, mostly through telehealth. With the implementation of the lockdown and dangers of COVID-19, the Health Professionals Council of South Africa relaxed its regulations on the use of telehealth, making it more accessible. Only one in four had access to a sports physician, perhaps due to financial or travelling constraints. The athletes accessed traditional and social media to gain knowledge on COVID-19 demonstrating the ability of these platforms to reach wide audiences to deliver key public health messages. It appears that doctors or other evidence-based platforms were poorly utilised for this purpose possibly because healthcare professionals did not reach out to the athlete population. Nevertheless, athletes had good knowledge about COVID-19 preventative measures and presenting symptoms. They identified handwashing with soap and water or the use of alcohol-based hand sanitisers as a priority in reduc-

ing their risk of contracting the virus. Applying respiratory hygiene was rated high while only one in two athletes recognised social distancing of >2 m as important. Even though athletes were aware of how to mitigate the risk, they lacked awareness of the priorities of risk modification.\(^4\) The timing of the survey may have contributed to athletes favouring the use of surgical and FFP1/FFP2/N95 masks (which should be reserved for healthcare professionals), instead of a cloth mask. Cloth masks have shown some potential to reduce the risk of viral transmission.\(^5\) This information was shared by the government shortly before the start of the survey, which may have biased the responses.\(^3\) The athletes also correctly recognised the most significant symptoms of COVID-19 as communicated by the World Health Organisation,\(^10\) NICD\(^11\) and National Department of Health,\(^36\) being shortness of breath, fever, dry cough and a sore throat. Almost all athletes knew how to proceed if they suspected having contracted the SARS-CoV-2 virus. Three out of four athletes know they should either contact their doctors, or the NICD toll-free number for guidance. These findings underline the vital role and efficacy of high quality messaging in traditional and social media in a pandemic.

Athletes are keen to RTS, and the majority of athletes are even prepared to do so behind closed doors.\(^32\) However, one in three athletes were unsure when to RTS, possibly owing to global uncertainty about the pandemic, lack of communication by national and international federations and sport governing bodies. One out of two athletes were comfortable to RTS when advised, the other half was unsure or would not return. Established protocols, risk mitigation strategies, guidance from sports federations and government following international trends, and financial support from federations and/or provision of protective equipment were some of the requirements identified by the athletes. Continuous athlete education to promote required behaviours, preparing the environment and health screening to evaluate COVID-19 status prior to RTS is needed.\(^39\) Physiological readiness to RTS should include re-evaluating weight, blood pressure, liver function, glucose, glycated haemoglobin and lipid profiles.\(^39\) Then a stepwise and sport-specific return to training, synchronised with the expected gradual lifting of restrictions of movement and social distancing is advised.\(^38\)

High load, training load fluctuations that negatively impact acute:chronic load ratios are known injury risk factors.\(^13,14\) Accelerated RTS after the lockdown of NFL athletes in 2011, subsequently lead to high injury rates.\(^12\) Ongoing monitoring of training loads, injury and illness upon RTS and addressing any deficits regarding the level of conditioning, strength, proprioception, neuromuscular activation and sport-specific conditioning following this period of lockdown, is recommended.\(^40\)–\(^42\) Further, nutrition, sleep, mental and general health issues related to restriction of movement should be addressed\(^40\)–\(^42\) and supported through the RTS process.\(^43\) It is also important to control the possible spreading of the virus during RTS, as well as managing the progress of the pandemic by early detection and management of new cases in the sports community to mitigate a second wave.\(^23,38\)

The majority of our study participants were males, with the sex distribution of our participants being representative of the current South African athlete population.\(^25\) Convenience sampling was used and team sports were overrepresented, thus the findings may not be generalisable to individual sports. We did not require athletes to report pre-lockdown sleep patterns, mental status or supplement use thus findings cannot be comparable to pre-lockdown habits. We did not specifically differentiate between guided or unguided training programmes, even though there was an option to indicate guidance by professionals. The study was open for only 72 h and may have limited the response rate. This short access period was necessary to allow timely data analyses and planning of implementation measures and advice before RTS. Additionally owing to availability of resources, we were unable to verify the level of evidence of websites, social media platforms or other sources of information used by athletes. We also did not specifically ask why athletes opted for advice from non-medical experts or how finances were affected.

5. Conclusion

COVID-19 has significant physical and mental effects on athletes including physical deconditioning, altered sleep patterns, worsening nutrition, uncertainty on RTS and feelings of depression. Athletes are well informed on the COVID-19 disease, however, the need remains to provide them with easy access to reliable evidence-based resources. Closer medical, nutritional and psychological support during and after the lockdown is recommended. Further, lost opportunities and uncertain financial and sporting futures may have long-lasting effects on both athletes and the sports industry. Re-adjustment to normal life and RTS will undoubtedly be challenging. Even though the international focus seems to be on RTS, this study shows that there are many other lifestyle challenges needing to be overcome prior to returning to a pre-COVID-19 normality. Governments and sporting federations should develop and implement regional and sport-specific
Table 5
Athlete responses to healthcare and knowledge on COVID-19 during lockdown.

| Questions on healthcare during lockdown | Do you have easy access to your healthcare professionals? | Is your access via telehealth? | Which professionals do you have access to? | Knowledge on COVID-19 during lockdown |

Conflict of interest

The authors report no conflict of interest pertaining to this manuscript.

Data sharing statement

No additional data are available.

Acknowledgements

The authors made available all contact numbers and data-free websites for the DOH, NICD as well as several pharmaceutical and private based companies providing telephonic support for depression.

The authors would like to thank the following medical colleagues, athletes and sport administrators for distributing the survey: Dr Kevin Subban, Cheryl Roos, Zac van Heerden, Lance Stevens, Belinda Waghorn, Denise Polson, Calvin Shipley, Nick Brink, Josh Smith, Tim Vadachallam, Denis Riehbok, Kelvin Ndliomo, John Williams, Warren Engelbrecht, Kutlwano Molefe, Christy Cronin, Neline Hoffman, Bernadette Costons, Rayno Rayepen, Dr Janesh Ganda, Fanie de Klerk, Dr Abdulrah Moola, Elana Meyer, Nolene ConradJacques Durand, Steven Ball, Marianne Viljoen, Jason Fyfer, Setty Ndaba, Siphelele Mthembu, Non Pongolo, Ryan Rickelton, Mangaliso Mosehle, Nolene Conrad, Rene Kalmer, Raisibe Ntokizane, Craig Cynkin, Shannon Naidoo, Granald Scott, Roori Mahamutsa, Ludwe Mpkupaku.

The authors would like to express their gratitude to Mrs Madeleen Scheckers for the upload of all publications to Endnote library.
