Generalized photon-subtracted squeezed vacuum states

Sanjib Dey$^1$ and Sarika S. Nair$^1$

$^1$Department of Physical Sciences, Indian Institute of Science Education and Research Mohali, Sector 81, SAS Nagar, Manauli 140306, India

We construct a generalized version of the photon-subtracted squeezed vacuum states (PSSVS), which can be utilized to construct the same for nonlinear, deformed and any usual quantum mechanical models beyond the harmonic oscillator. We apply our general framework to trigonometric Pöschl-Teller potential and show that our method works accurately and produces a proper nonclassical state. We analyze the nonclassicality of the state using three different approaches, namely, quadrature squeezing, photon number squeezing and Wigner function and indicate how the standard definitions of those three techniques can be generalized and utilized to examine the nonclassicality of any generalized quantum optical states including the PSSVS. We observe that the generalized PSSVS are always more nonclassical than those arising from the harmonic oscillator. Moreover, within some quantification schemes, we find that the nonclassicality of the PSSVS increases almost proportionally with the number of photons subtracted from the generalized squeezed vacuum state. Thus, generalized PSSVS may provide an additional freedom with which one can regulate the nonclassicality and obtain an appropriate nonclassical state as per requirement.

I. INTRODUCTION

Wigner function is an excellent framework for the study of quantum optical states. States with Gaussian Wigner function have certain applications in quantum information processing and they have been studied extensively in the literature. More recent studies show that the states with non-Gaussian Wigner function are also very important in the field, especially those having a negative Wigner function. Negativity in Wigner function is a sufficient condition for nonclassicality and the associated states are extremely useful in entanglement distillation [1], quantum computing [2], etc. Several important non-Gaussian states have been studied and are found to exist in real life. For instance, in [3], the authors reveal an experimental method for preparing non-Gaussian states from a single mode squeezed light using the homodyne detection technique. A similar technique was utilized to detect a single-photon state in [4]. Besides, there are plenty of experimental results for the preparation of various nonclassical states including Schrödinger cat states [5], squeezed states [6], photon-subtracted squeezed/squeezed vacuum states [7], etc.

While standard quantum optical non-Gaussian states have immense importance, a lot of recent studies indicate that the generalized quantum optical states play an important role in quantum information processing, see: for instance [8, 9] for some reviews on the development. Generalization to quantum optics can be performed in various ways, some of the well-known approaches include the nonlinear generalization [10–12], q-deformation [13, 14], etc. A common goal in all such frameworks is to construct the quantum optical states for other quantum mechanical potentials apart from the harmonic oscillator. One of the notable usefulness of generalizing the quantum optical models is that it brings in additional degrees of freedom to the system by which one can improve several crucial properties of the system [15]. More importantly, it has been shown that generalized nonclassical states provide higher degree of nonclassicality compared to the usual nonclassical states [16-18], which can be exploited to enhance the quantum entanglement of various nonclassical states within some protocols [19-21]. The usage of the generalized quantum optical states is not limited to the theoretical studies but there have been ample experimental investigations based on Kerr type nonlinear cavities [22–24].

In this article, we construct a class of non-Gaussian nonclassical states, namely the photon-subtracted squeezed vacuum states (PSSVS) arising from the generalized framework. We provide a generic analytical prototype which can be utilized to construct generalized PSSVS for any nonlinear, deformed and quantum mechanical models. As per the definition, the states are bound to exhibit nonclassical properties, which we verify using several independent methods, namely, quadrature squeezing, photon distribution function and negativity in Wigner function. One of the striking features of such states is that the nonclassicality increases proportionally with the number of photons being subtracted from the states, which is visible evidently in two of our approaches, the number squeezing and the Wigner function. Therefore, such states may be employed methodically to produce more nonclassicality compared to the generalized squeezed vacuum states. We also notice that the generalized PSSVS are always more nonclassical than those emerging from the harmonic oscillator potential, and such a phenomenon occurs consistently in all three given methods. Thus, we believe that such states will be a compelling successor for quantum information theories in many aspects.

In Sec.II, we describe the methodology for the construction of generalized PSSVS along with a complete analytical description of the states. Sec.III is composed of the solution of the Pöschl-Teller potential and a contemporary procedure for extracting the required informa-
II. GENERALIZED PHOTON-SUBTRACTED SQUEEZED VACUUM

PSSVS can be constructed by subtracting single or multiple number of photons from the squeezed vacuum states [25]. Before moving to the full fledged construction of generalized PSSVS, let us commence with the discussion of the method of construction of the harmonic oscillator squeezed vacuum states $|\zeta\rangle$. Usually, it follows from the operation of the squeezing operator $\hat{S}(\zeta) = \exp\left([\zeta^*\hat{a}^2 - \zeta^2\hat{a}^\dagger]/2\right)$ on the vacuum state $|0\rangle$ and the result is entirely equivalent to that obtained from the following definition [26]

$$\left(\hat{a}\mu + \hat{a}^\dagger\lambda\right)|\zeta\rangle = 0,$$

with $\mu = \cosh r$ and $\lambda = e^{i\theta}\sinh r$. Here, the squeezing parameter $\zeta$ is represented in the polar form $\zeta = r e^{i\theta}$. Note that the relation (1) does not originate from an independent source, rather, it is a byproduct of the first definition $|\zeta\rangle = \hat{S}(\zeta)|0\rangle$. It is worth mentioning that several mixed terminologies are used for such states in the literature, for example, in [25], the authors claim that they study the squeezed states, however, originally they have studied the squeezed vacuum states. We stay clear of this confusion by specifying the states as follows. We attribute the name ‘squeezed vacuum states’ to the states that are generated by the action of the squeezing operator $\hat{S}(\zeta)$ on the vacuum state $|0\rangle$, i.e. $|\zeta\rangle = \hat{S}(\zeta)|0\rangle$. However, when we refer the ‘squeezed states’, we mean the states originating from the operation of the squeezing operator on the coherent states $|\alpha\rangle$ instead, viz. $|\zeta,\alpha\rangle = \hat{S}(\zeta)|\alpha\rangle$. In this article, we study the generalization of squeezed vacuum states $|\zeta\rangle$. Nevertheless, the first step towards the generalization is to find a general set of ladder operators $\hat{A} \equiv \hat{a} f(\hat{n}) = f(\hat{n}+1)\hat{a}^\dagger$, $\hat{A}^\dagger \equiv f(\hat{n})\hat{a} = \hat{a}^\dagger f(\hat{n}+1)$, whose action on the Fock states can be realized as follows

$$\hat{A}|n\rangle = \sqrt{n}f(n)|n-1\rangle,$$

$$\hat{A}^\dagger|n\rangle = \sqrt{n+1}f(n+1)|n+1\rangle,$$

so that the number operator of the generalized system can be considered as $\hat{A}^\dagger \hat{A} \equiv \hat{n} f^2(\hat{n})$. Here $f(\hat{n})$ is an operator valued function of the harmonic oscillator number operator $\hat{n} \equiv \hat{a}^\dagger \hat{a}$ and, it is an entirely general function. The exact expression of $f(\hat{n})$ can be extracted from the knowledge of the eigenvalues of the corresponding Hamiltonian assuming that it can be factorized in terms of the generalized number operator $\hat{A}^\dagger \hat{A}$. Any constant terms that may appear in the Hamiltonian can be realized by a proper rescaling of the eigenvalues of the composite system containing $\hat{A}$ and $\hat{A}^\dagger$. Thus, the knowledge of the eigenvalues of any quantum mechanical Hamiltonian will ensure the explicit form of the function $f(n)$. The method is usually familiar as the nonlinear generalization [10–12] and the endeavor has been accepted widely; see, for instance [27–33]. However, a direct replacement of the generalized ladder operators (2) in (1) does not necessarily yield the generalized PSSVS, rather, the resulting states is some other state whose name is not known to us. Indeed there exist some studies where the generalized ladder operators (2) have been used directly in (1), see; for instance [34], however, the results following such an approach may be regarded incorrect. Notice that the relation $(\hat{A}\mu + \hat{A}^\dagger\lambda)|\zeta,f\rangle = 0$ does not originate from the original definition of generalized squeezed vacuum states, i.e. $|\zeta,f\rangle = \hat{S}(\zeta,f)|0\rangle$. This is because the generalized ladder operators satisfy the commutation relation

$$[\hat{A},\hat{A}^\dagger] = (\hat{n}+1)f^2(\hat{n}+1) - \hat{n}f^2(\hat{n}),$$

and, thus, the generalized squeezing operator $\hat{S}(\zeta,f) = \exp\left([\zeta^*\hat{a}^2 - \zeta^2\hat{a}^\dagger]/2\right)$ can no longer be disentangled. Therefore, it is impossible to reach to the definition $(\hat{A}\mu + \hat{A}^\dagger\lambda)|\zeta,f\rangle = 0$ from the original definition $|\zeta,f\rangle = \hat{S}(\zeta,f)|0\rangle$. To overcome this problem, let us introduce a set of auxiliary ladder operators $\hat{B} = \hat{a}[1/f(\hat{n})] = [1/f(\hat{n}+1)]\hat{a}$ and $\hat{B}^\dagger = [1/f(\hat{n})]\hat{a}^\dagger = \hat{a}^\dagger [1/f(\hat{n}+1)]$ resulting to a new set of commutation relations $[\hat{A},\hat{B}^\dagger] = [\hat{B},\hat{A}^\dagger] = 1$. Therefore, one can consider a new set of conjugate ladder operators $\hat{A},\hat{B}^\dagger$ or $\hat{B},\hat{A}^\dagger$ which will allow the disentanglement of the squeezing operator. The method was introduced in [35] in order to explore a new type of coherent states which become compatible with both of the definitions of nonlinear coherent states, $|\alpha,f\rangle = \hat{D}(\alpha,f)|0\rangle$ and $|\alpha,f\rangle = \alpha|\alpha\rangle$, with $D(\alpha,f) = \exp[\alpha\hat{A}^\dagger - \alpha^*\hat{A}]$ being the optical displacement operator.

Let us now describe an appropriate way to construct the generalized squeezed vacuum states. We define the squeezed vacuum as

$$|\zeta,f\rangle = \hat{S}(\zeta,f)|0\rangle = e^{\frac{i}{2}(\zeta^*\hat{A}^\dagger - \zeta\hat{B}^\dagger)}|0\rangle,$$

which leads to the alternative definition

$$\left(\hat{A}\mu + \hat{B}^\dagger\lambda\right)|\zeta,f\rangle = 0,$$

with $\mu = \cosh r$ and $\lambda = e^{i\theta}\sinh r$. It is straightforward to check that the relation (4) leads to (5). Considering the state $|\zeta,f\rangle$ to be residing in the photon number space $|n\rangle$, we can decompose the state in the Fock basis, i.e. $|\zeta,f\rangle = \sum_{n=0}^{\infty} C_{n,f}|n\rangle$. Thereafter, using this expression in (5), we obtain the recursion relation for the expansion coefficients

$$C_{m+1,f} = -\frac{e^{i\theta}\tanh r}{f(m)f(m+1)} \sqrt{\frac{m}{m+1}} C_{m-1,f},$$

which when solved in the even basis, we obtain the required state as follows

$$|\zeta,f\rangle = \frac{1}{N_{\zeta,f}} \sum_{n=0}^{\infty} (-1)^n \frac{e^{i\theta}(\tanh r)^n}{2^n n! f(2n)!} |2n\rangle.$$
The normalization constant is given by
\[ N_{f,m}^2 = \sum_{n=0}^{\infty} \frac{(2n)![(\tanh r)^{2n}]}{4^n(n!)^2[f(2n)!]^2} \tag{8} \]

Note that the solution of (6) in the odd basis will lead to the generalized squeezed first excited state and we are not interested in it. We shall rather explore the effects of the photon subtraction from the generalized squeezed vacuum states (7).

The generalized PSSVS can, in principle, be constructed by subtracting \( m \) number of photons from the squeezed vacuum states (7), i.e., by operating \( \hat{A}^m \) on the state \( |\zeta, f\rangle \). However, subtraction of arbitrary number of photons will impose a restriction on the state that \( 2n-m \) has to be positive. We can avoid such a restriction by studying the states in even and odd bases separately and the closed forms of the generalized PSSVS are given by
\[ |\zeta, f, m\rangle_e = \hat{A}^{2m}|\zeta, f\rangle \]
\[ = \frac{1}{N_{\zeta, f,m}^e} \sum_{n=0}^{\infty} \frac{(-\tanh r)^k e^{ik\theta}(2k)!}{2^k k! f(2n)!} |2n\rangle \]
and
\[ |\zeta, f, m\rangle_o = \hat{A}^{2m+1}|\zeta, f\rangle \]
\[ = \frac{1}{N_{\zeta, f,m}^o} \sum_{n=0}^{\infty} \frac{(-\tanh r)^k e^{ik\theta}(2k')!}{2^k k'! f(2n+1)!} |2n+1\rangle \]
with the normalization constants being
\[ [N_{\zeta, f,m}^e]^2 = \sum_{n=0}^{\infty} \frac{(\tanh r)^{2k}[(2k)!]^2}{4^k(k!)^2(2n)!(f(2n)!)^2}, \tag{11} \]
\[ [N_{\zeta, f,m}^o]^2 = \sum_{n=0}^{\infty} \frac{(\tanh r)^{2k'}[(2k')!]^2}{4^k(k'!)^2(2n+1)!(f(2n+1)!)^2}, \tag{12} \]
where \( k = m + n \) and \( k' = k + 1 \). Here \( m \) is absolutely arbitrary and replacement of \( m = 0 \) in (9) and (10) yield the squeezed vacuum states and single PSSVS, respectively.

III. THE MODEL

The formalism that we have proposed here is entirely general and, thus, it can be applied to any quantum mechanical, nonlinear or even to any deformed quantum mechanical scenarios. The only task is to extract the value of the function \( f(n) \) from the given model. In this article, we shall utilize the standard solutions of the trigonometric Pöschl-Teller potential and show how one can construct the PSSVS for such a systems and explore their nonclassical properties. The explicit form of the potential is [36]
\[ V(x) = \frac{\hbar^2}{8ma^2} \left[ \frac{\lambda(\lambda-1)}{\cos^2 \frac{x}{2\alpha}} + \frac{\kappa(\kappa-1)}{\sin^2 \frac{x}{2\alpha}} - (\lambda + \kappa)^2 \right], \tag{13} \]
and the corresponding eigenvalues and eigenfunctions are given by
\[ \psi_n(x) = N(\kappa, \lambda) \left( \cos \frac{x}{2\alpha} \right)^\lambda \left( \sin \frac{x}{2\alpha} \right)^\kappa \times 2F_1 \left( -n, n + \lambda + \kappa; \frac{1}{2}; \sin^2 \frac{x}{2\alpha} \right), \]
\[ E_n = \frac{\hbar^2}{2ma^2} n(n + \lambda + \kappa). \tag{15} \]
The above solutions are readily available in the literature, see; for instance, [36]. Depending on the values of the parameters \( \lambda \) and \( \kappa \), one can interpret the potential (13) in many ways, for further details one may refer [36]. However, in our analysis we have chosen \( \lambda = \kappa = 1 \) resulting to a symmetric Pöschl-Teller potential. As per our formalism, we can assume that the Hamiltonian can be factorized in terms of the generalized ladder operators (2) as \( \hat{H} = \hat{A}^\dagger \hat{A} \) to reproduce the spectrum (15). Thus, the number operator can be considered as \( \hat{N} = \hat{A}^\dagger \hat{A} = \hat{n} f^2(\hat{n}) \), with
\[ f(n) = (n + \lambda + \kappa)^{1/2}, \tag{16} \]
which when replaced in (9) and (10) one obtains the even and odd PSSVS, respectively, for the corresponding model. Note that, we have chosen the values of \( h, \alpha \) and \( a \) in such a way that the factor \( \hbar^2/2ma^2 \) in (15) becomes unity. It is possible to realize the number operator in an alternative way also, for instance, we can define it in the following way
\[ \hat{N} = \left[ \hat{A}^\dagger \hat{A} + \frac{1}{4}(\lambda + \kappa)^2 \right]^{1/2} - \frac{1}{2}(\lambda + \kappa). \tag{17} \]
There are several advantages against such a choice, firstly, \( \hat{N} \) in (17) becomes equivalent to the usual photon number operator \( \hat{n} = \hat{A}^\dagger \hat{A} \) in the sense that \( \hat{N}(n) = \hat{n}(n) = n(n) \). That means although the information of the generalized model is hidden inside \( \hat{N} \) in terms of \( f(n) \), it still produces a physical photon, whereas \( \hat{N}' = \hat{A}^\dagger \hat{A} \) does not. Owing to such an interesting physical outcome, we are more interested in choosing the number operator given by (17) in the rest of our analysis. Interestingly, we observe that the Hamiltonian can be factorized in terms of the new number operator \( \hat{N} \) also as \( \hat{H} = \hat{N}(\hat{N} + \lambda + \kappa) = \hat{A}^\dagger \hat{A} = \hat{N} f^2(\hat{N}) \), with
\[ f(N) = (N + \lambda + \kappa)^{1/2}, \tag{18} \]
so that one can identify \( \hat{N} \) to be equivalent to \( \hat{n} \). Therefore, while choosing the function \( f(n) \) it becomes immaterial whether one takes it from (16) or (18), physically they are same.

IV. SIGNATURE OF NONCLASSICALITY

Any states which are less classical than the coherent states are familiar as nonclassical states. In other words,
nonclassicality is a measure of quantumness of a state with reference to the Glauber coherent state. In our analysis, our purpose is to explore the nonclassical properties of generalized even and odd PSSVS and, we shall quantify the nonclassicality with respect to the Glauber coherent states. Generalized coherent states are already known to be nonclassical [21, 37, 38] while measuring it with respect to the Galuber coherent states, thus, we do not measure the nonclassicality of generalized PSSVS with respect to the generalized coherent states.

A. Squeezing in quadratures

First, we define the quadrature operators for the generalized system as $\hat{X} = (\hat{A} + \hat{A}^\dagger)/\sqrt{2}$ and $\hat{P} = (\hat{A} - \hat{A}^\dagger)/\sqrt{2}$, so that they obey the generalized Robertson uncertainty relation

$$\Delta \hat{X} \Delta \hat{P} \geq \frac{1}{2} |\langle \cdot | [\hat{X}, \hat{P}] |\cdot \rangle|.$$  \hspace{1cm} (19)

We are bound to replace the standard definition of the quadrature operators by the new definition as mentioned above, since any observable out of our generalized system has to be composed of the generalized ladder operators by construction. This, in turn, demands a modification of the definition of the quadrature squeezing itself, since we have to deal with the factor $f(n)$ that are associated with the generalized ladder operators. The replacement of Heisenberg uncertainty relation by the Roberson uncertainty relation would accomplish the job, as the RHS of generalized uncertainty relation (19) consists of the commutator $[\hat{X}, \hat{P}]$ within which the signature of the function $f(n)$ is underlain. While computing (19) using the vacuum state, the square root of the RHS of (19) and each of the variances turns out to be equal, viz. $\Delta \hat{X} = \Delta \hat{P} = \sqrt{\langle 0 | [\hat{X}, \hat{P}] |0 \rangle}/2 = \sqrt{f(1)/2}$, and the same result can be obtained using the some deformed coherent states also [16]. However, this may be true only for certain coherent states and it is not guaranteed to hold for any arbitrary generalized state. This is because the commutator $[\hat{X}, \hat{P}]$ is not proportional to the identity operator in general, thus, the result of the RHS of (19) is dependent on the state that is used to compute the expectation values. Therefore, it is not guaranteed that the variances corresponding to the generalized PSSVS are necessarily below to those of the vacuum state, as it happens in the case of harmonic oscillator. In our case, the quadrature squeezing does not correspond to the case when the variance of any of the quadratures becomes lower than the square root of the RHS of (19) for the vacuum state, but, it corresponds to that of the particular state that is being studied, which is $|\zeta, f, m\rangle_{e/o}$ in

Figure 1. (Color online) Square of the uncertainties of $X$ and $P$ quadratures for even generalized PSSVS for $m = 1$ in (a) & (d), $r = 1$ in (b) & (e) and $\theta = 0$ in (c) & (f). In all the plots $\lambda$ and $\kappa$ are chosen to be 1.5. The yellow surfaces in all the figures show the variation of the RHS of the generalized Robertson uncertainty relation.
In our case, we first need to compute the expectation values of ladder operators $\hat{A}$, $\hat{A}^{\dagger}$ and their squares using the states $|\zeta,f,m\rangle_{e/o}$. The expectation values of $\hat{A}$ and $\hat{A}^{\dagger}$ for both even and odd PSSVS can clearly be understood to be vanished, because $\hat{A}$ operating on the even/odd state will surely lead to zero. The same reasoning can be applied to $\hat{A}^{\dagger}$. Thus,

$$e/o\langle\zeta,f,m|\hat{A}|\zeta,f,m\rangle_{e/o} = 0$$  \hspace{1cm} (20)
$$e/o\langle\zeta,f,m|\hat{A}^{\dagger}|\zeta,f,m\rangle_{e/o} = 0.$$  \hspace{1cm} (21)

The expectation values of the squares of $\hat{A}, \hat{A}^{\dagger}$ are computed as follows

$$e\langle\hat{A}^{\dagger}\hat{A}\rangle_{e} = \frac{-e^{i\theta}}{N_{\zeta,f,m}^{e/o}} \sum_{n=0}^{\infty} \frac{(\tanh r/2)^{2k+1}(2k)!(2k+2)!}{k!(k+1)!(2n)!(f(2n+1))!}$$  \hspace{1cm} (22)
$$o\langle\hat{A}^{\dagger}\hat{A}\rangle_{o} = \frac{-e^{i\theta}}{N_{\zeta,f,m}^{e/o}} \sum_{n=0}^{\infty} \frac{(\tanh r/2)^{2k+3}(2k+2)!(2k+4)!}{(k+1)!(k+2)!(2n+1)!(f(2n+1))!}$$  \hspace{1cm} (23)

with $e\langle\hat{A}^{2}\rangle_{e} = e\langle\hat{A}^{\dagger}\hat{A}\rangle_{e}^{*}$ and $o\langle\hat{A}^{2}\rangle_{o} = o\langle\hat{A}^{\dagger}\hat{A}\rangle_{o}^{*}$. Finally, we compute

$$e\langle\hat{A}^{\dagger}\hat{A}\rangle_{e} = \frac{1}{N_{\zeta,f,m}^{e/o}} \sum_{n=0}^{\infty} \frac{2^{-2k}[(2k)!]^2(2n+1)!(f(2n+1))!^2}{(\tanh r)^{-2k}[k]!(2n)!}$$
$$o\langle\hat{A}^{\dagger}\hat{A}\rangle_{o} = \frac{1}{N_{\zeta,f,m}^{e/o}} \sum_{n=0}^{\infty} \frac{\text{[(tanh } r/2)^{2k+2}[(2k+2)!]^2}}{[(k+1)!]^2(2n+1)!} \times \frac{2^{2k+2}[(2k+2)!][2n+1]!}{[f(2n+1)]!}$$  \hspace{1cm} (27)

so that the variance of the quadratures $\hat{X}$ and $\hat{P}$ can be calculated as $(\Delta_{\hat{X}_{e/o}})^2 = e/o\langle\hat{X}^{2}\rangle_{e/o} = e/o\langle\hat{A}^{\dagger}\hat{A}\rangle_{e/o} + e/o\langle\hat{A}^{\dagger}\hat{A}\rangle_{e/o} + e/o\langle\hat{A}^{2}\rangle_{e/o} + e/o\langle\hat{A}^{\dagger}\hat{A}\rangle_{e/o})/2$ and $(\Delta_{\hat{P}_{e/o}})^2 = e/o\langle\hat{P}^{2}\rangle_{e/o} = (e/o\langle\hat{A}^{\dagger}\hat{A}\rangle_{e/o} + e/o\langle\hat{A}^{\dagger}\hat{A}\rangle_{e/o} - e/o\langle\hat{A}^{2}\rangle_{e/o} - e/o\langle\hat{A}^{\dagger}\hat{A}\rangle_{e/o})/2$, respectively. The numerical studies of the variances for $\hat{X}$ and $\hat{P}$ quadratures with respect to different parameters are depicted in Fig. 1 for even states and...
in Fig. 2 for the odd states. The yellow surfaces in each of the plots represent the variation of the RHS of the generalized Robertson uncertainty relation. Thus, any portion of the variances of the quadratures which falls below the yellow surface clearly identifies the squeezing of quadrature. We observe that the quadratures are squeezed in all the cases (at least partially in certain regime) except in Fig. 1(f) and 2(f), where we have fixed the value of $\theta = 0$. However, this is purely because of the choice of $\theta$. If we would have chosen the value of $\theta$ at around 4 (in the appropriate unit) to re-plot the Fig. 1(f), we would have obtained the squeezing in $P$ quadrature also. This can be ensured by a careful observation of Fig. 1(e). A similar type of argument is also true for the Fig. 2(f). Nevertheless, we notice that the variation of the quadrature is periodic in $\theta$ and one must choose the value of the parameter $\theta$ appropriately to obtain the squeezing in both of the quadratures (of course, not at the same time, but alternatively).

![Figure 3](image_url)

**Figure 3.** (Color online) Number squeezing $N_s^e$ for even PSSVS for generalized cases $f(n) = \sqrt{n + \kappa + \lambda}$ in (a) and (b) for $\lambda = \kappa = 1.5$, and for harmonic oscillator cases $f(n) = 1$ in (c) and (d).

B. Photon statistics

The study of photon statistics in the generalized case, in principle, also requires a modification over the standard method. Usually the photon number of a quantum optical state is said to be squeezed if the distribution function corresponding to the state is sub-Poissonian and the signature of nonclassicality/squeezing is easily captured by utilizing the Mandel parameter $Q = \langle (\Delta \hat{n})^2 \rangle / \langle \hat{n} \rangle - 1$ [39]. Notice that when the distribution is Poissonian, i.e. $\langle (\Delta \hat{n})^2 \rangle = \langle \hat{n} \rangle$ (which is also the characteristics of Glauber coherent states), the Mandel parameter turns out to be zero. A negative Mandel parameter indicates a sub-Poissonian statistics of the photon distribution. Thus, a simple computation of the mandel parameter can ensure the nature of the photon distribution in the standard harmonic oscillator cases. A straightforward generalization of the Mandel parameter with the generalized ladder operators (2) would look like $Q_s = \langle (\Delta \hat{N})^2 \rangle / \langle \hat{N} \rangle - 1$. However, $Q_s$ may not be able to detect the sub-Poissonian statistics properly. This is because in a general scenario, $\langle (\Delta \hat{N})^2 \rangle$ may not be equal to $\langle \hat{N} \rangle$ while computed using the Glauber coherent states. It is also not legitimate to calculate the averages using the nonlinear coherent states, since they are known to be nonclassical. A more secure way is to check whether the condition $\langle (\Delta \hat{N})^2 \rangle < \langle \hat{N} \rangle$ is valid or not, in other words we can compute $N_s^e = \langle (\Delta \hat{N})^2 \rangle - \langle \hat{N} \rangle$ and if it is negative, we can affirm the nonclassicality of the state. Therefore, it is clear that we measure the nonclassicality of the state with respect to a Poissonian distribution.
two expressions \(N\) both of them will give rise to the same result. For given in (17), we can use both of the approaches, and \(N\) applied to the generalized models. However, if we choose we are bound to follow the second method which is ap-

plied to the generalized models. However, if we choose \(N\) given in (17), we can use both of the approaches, and both of them will give rise to the same result. For convenience, we consider the second method and compute \(N^{s/o}_{e/o} = e/o(\Delta N)^2_{e/o} - e/o(N)_{e/o}\) by using the following two expressions

\[
e/o(N)_{e/o} = \left\langle A^\dagger A + \frac{(\lambda + \kappa)^2}{4} \right\rangle_{e/o} - \frac{\lambda + \kappa}{2}, \tag{28}
\]

\[
e/o(N^2)_{e/o} = e/o(\Delta A)_{e/o} = (\lambda + \kappa)_{e/o} \langle N \rangle_{e/o}. \tag{29}
\]

It is straightforward to calculate the expressions in (28) and (29) by using (25) and (27), and the results are shown in Fig. 3 and 4 for even and odd PSSVS, respectively. In Fig. 3(a) and 3(c), we plot the variation of \(N^{s/o}_{e/o}\) with respect to \(s\) as a function \(m\) for generalized and harmonic oscillator PSSVS, respectively. Fig. 3(a) demonstrates negative values of \(N^{s/o}_{e/o}\), whereas no negative region is visible in Fig. 3(c), which indicates that the photon distribution for generalized PSSVS is squeezed. A similar thing happens in Fig. 3(b) and 3(d) also, where we plot the variation of \(N^{s/o}_{e/o}\) with respect to \(m\). Overall, we observe that the photon number distribution is always squeezed in generalized even PSSVS (provided that we choose the \(r\) and \(m\) values properly), and corresponding states are nonclassical, but the PSSVS for corresponding to harmonic oscillator are not nonclassical. In case of odd PSSVS, we obtain even better results, which we show in Fig. 4. Here, we do not see any positive value of \(N^{s/o}_{e/o}\) for generalized PSSVS, whereas, the \(N^{s/o}_{e/o}\) for harmonic oscillator PSSVS are always positive.

C. Negativity of the Wigner distribution function

In order to obtain the Wigner distribution function in our case, we shall incorporate the expressions of generalized PSSVS \(|\zeta,f,m\rangle_{e/o}\) from (9) and (10) in its usual form [18, 40]

\[
W(z)_{e/o} = e^{2|z|^2} \int \frac{d^2\beta}{\pi^2} \langle -\beta|\zeta,f,m\rangle_{e/o} e^{i\beta z} e^{i\beta^* z^*} \times 2e^{2(\beta^* z - \beta z^*)}, \tag{30}
\]

where \(z,\beta\) are the eigenvalues of the Glauber coherent states. As we stated earlier that our aim is to quantify the nonclassicality of the generalized PSSVS with re-
spect to the Glauber coherent states, therefore, we must take the inner products between the generalized PSSVS $| \zeta, f, m \rangle_{e/o}$ and the Glauber coherent states $| \beta \rangle$ in (30). While we utilize the exact form of the even and odd PSSVS from (9) and (10) in (30) and introduce a change of variable $\gamma = 2z$, we obtain

$$W(\gamma)_{e/o} = e^{i\gamma^2/2} \sum_{l_1, l_2=0}^{\infty} C_{l_1, l_2}^{e/o} F_{l_1, l_2}^{e/o}(\gamma),$$

with

$$C_{l_1, l_2}^{e} = \frac{2(-\tanh r/2)k_1^2 + k_2^2 e^{i(l_1 - l_2)}(2k_1)!(2k_2)!}{\pi N_{\xi, f, m}^{e} k_1! k_2! \sqrt{(2l_1)!(2l_2)!} f(2l_1)! f(2l_2)!},$$

$$C_{l_1, l_2}^{o} = \frac{2N_{\xi, f, m}^{o} (-\tanh r/2)k_1^2 + k_2^2 e^{i(l_1 - l_2)}(2k_1)!(2k_2)!}{\pi k_1! k_2! \sqrt{(2l_1 + 1)!(2l_2 + 1)!} f(2l_1 + 1)! f(2l_2 + 1)!},$$

$$F_{l_1, l_2}^{e}(\gamma) = \left( -1 \right)^{2(l_1 + l_2)} \frac{\partial^{2(l_1 + l_2)}}{\partial \gamma^{2l_1} \partial \gamma^{2l_2}} e^{-|\gamma|^2}.$$  

Here, we have used the identity $\int d^2 \sigma e^{-|\beta|^2} e^{i\beta^* - i\beta} = e^{-|\gamma|^2}$ and parameterized $k_1 = m + l_1, k_2 = m + l_2, k_1' = k_1 + 1, k_2' = k_2 + 1$. In order to write (34) in a more compact form, we shall utilize the fact that the derivative of any analytic function $f(z, z^*)$ with respect to $z$ is independent of $z^*$ and vice-versa, as well as employ the Rodrigues formula for the associated Laguerre polynomials to obtain

$$F_{l_1, l_2}^{e}(\gamma) = \left\{ \begin{array}{ll} \sqrt{\frac{(2l_1)!(2l_2)!}{(2l_1 + 1)!(2l_2 + 1)!}} e^{-|\gamma|^2} (2z)^2 (2z^* + 2l_1 - l_2) L_{2l_1}^{(2l_1 - l_2)} (4|\gamma|^2), & l_2 \geq l_1 \\
\sqrt{\frac{(2l_1)!(2l_2)!}{(2l_1 + 1)!(2l_2 + 1)!}} e^{-|\gamma|^2} (2z^*)^2 (2l_1 - l_2) L_{2l_2}^{(2l_1 - l_2)} (4|\gamma|^2), & l_2 \leq l_1, \end{array} \right. \label{eq:35}$$

where we have have restored the original variable by identifying $z = \gamma/2$. The function $F_{l_1, l_2}^{e}(\gamma)$ corresponding to the odd case is obtained by replacing all $2l_1$ and $2l_2$ in both (34) and (35) by $2l_1 + 1$ and $2l_2 + 1$, respectively. The behavior of the Wigner function for both the even and odd generalized PSSVS are shown in Fig. 5. In both of the cases, we find that the negativity in Wigner function becomes stronger while we subtract more photons from the squeezed vacuum states. For instance, in Fig. 5(a) we have taken $m = 14$ which implies that we have subtracted 28 photons, whereas in Fig. 5(b) $m = 1$, that means only 2 photons are subtracted, and it is clear that the nonclassicality in the former case is higher than the latter. A similar type of observation can also be made for the odd cases in Fig. 5(c) and 5(d). In these cases, although we do not notice an increase of negativity, but we see more negative peaks while higher number of photons are
and we observe that generalized PSSVS often demonstrate more nonclassicality compared to the harmonic oscillator cases. Thus, the generalized PSSVS provide a twofold enhancement of the nonclassicality with respect to the harmonic oscillator squeezed vacuum states and we believe that such states will bring fascinating outcomes for the study of quantum information.

So far, all results are theoretical, however, it is interesting to notice that the states can be constructed analytically and most of the analysis of nonclassicality can also be carried out analytically. A proper understanding of the states in the laboratory can be achieved only after the realization of some basic nonlinear quantum optical states in real life, which is currently under intense investigation. For the time being we believe that a lot of theoretical research are yet to be performed for a deeper understanding of the framework. As an immediate follow up, it would be worth studying the given protocol for some other general models and verify whether our results hold in those cases also, which may effectively shed some light on the given direction.
