A fourth-order compact time-splitting Fourier pseudospectral method for the Dirac equation

Weizhu Bao · Jia Yin

Received: date / Accepted: date

Abstract We propose a new fourth-order compact time-splitting ($S_{4c}$) Fourier pseudospectral method for the Dirac equation by splitting the Dirac equation into two parts together with using the double commutator between them to integrate the Dirac equation at each time interval. The method is explicit, fourth-order in time and spectral order in space. It is unconditional stable and conserves the total probability in the discretized level. It is called a compact time-splitting method since, at each time step, the number of sub-steps in $S_{4c}$ is much less than those of the standard fourth-order splitting method and the fourth-order partitioned Runge-Kutta splitting method. Another advantage of $S_{4c}$ is that it avoids to use negative time steps in integrating sub-problems at each time interval. Comparison between $S_{4c}$ and many other existing time-splitting methods for the Dirac equation are carried out in terms of accuracy and efficiency as well as long time behavior. Numerical results demonstrate the advantage in terms of efficiency and accuracy of the proposed $S_{4c}$. Finally we report the spatial/temporal resolutions of $S_{4c}$ for the Dirac equation in different parameter regimes including the nonrelativistic limit regime, the semiclassical limit regime, and the simultaneously nonrelativistic and massless limit regime.

1 Introduction

The Dirac equation was proposed by British physicist Paul Dirac in 1928 in order to integrate special relativity with quantum mechanics [29]. It successfully solved the problem that the probability density could be negative in the Klein-Gordon equation proposed by Oskar Klein and Walter Gordon in 1926 [28]. The Dirac equation describes the motion of relativistic spin-1/2 massive particles, such as electrons and quarks. It fully explained the hydrogen spectrum and predicted the existence of antimatter. Recently, the Dirac equation has been extensively adopted to investigate theoretically the structures and/or dynamical properties of graphene and graphite as well as other two-dimensional (2D) materials [1, 33, 49, 48], and to study the relativistic effects in molecules in super intense lasers, e.g., attosecond lasers [17, 36].

Consider the Dirac equation with electromagnetic potentials in three spatial dimensions (3D) [29, 30, 31, 60]

\[ i\hbar \partial_t \Psi = \left( -ic\hbar \sum_{j=1}^{3} \alpha_j \partial_j + mc^2 \beta \right) \Psi + e \left( V(\mathbf{x}) \mathbf{I}_4 - \sum_{j=1}^{3} A_j(\mathbf{x}) \alpha_j \right) \Psi, \quad \mathbf{x} \in \mathbb{R}^3, \tag{1.1} \]

where \( t \) is time, \( \mathbf{x} = (x_1, x_2, x_3)^T \) (or \( \mathbf{x} = (x, y, z)^T \)) is the spatial coordinate, \( \Psi := \Psi(t, \mathbf{x}) = (\psi_1(t, \mathbf{x}), \psi_2(t, \mathbf{x}), \psi_3(t, \mathbf{x}), \psi_4(t, \mathbf{x}))^T \in \mathbb{C}^4 \) is the complex-valued spinor wave function, and \( \partial_j \) represents \( \partial_{x_j} \) for \( j = 1, 2, 3 \). The constants used in the equation are: \( i = \sqrt{-1} \), \( \hbar \) is the Planck constant, \( m \) is the mass, \( c \) is the speed of light and \( e \) is the unit charge. In addition, \( V := V(\mathbf{x}) \) is the time-independent electric potential and \( \mathbf{A} := A(\mathbf{x}) = \left( A_1(\mathbf{x}), A_2(\mathbf{x}), A_3(\mathbf{x}) \right)^T \) stands for the time-independent magnetic potential, which are all real-valued given functions. Finally, the \( 4 \times 4 \) matrices \( \beta \) and \( \alpha_j \) \( (j = 1, 2, 3) \) are the Dirac representation matrices of the four-dimensional Clifford algebra, which are given as

\[
\beta = \begin{pmatrix} I_2 & 0 \\ 0 & -I_2 \end{pmatrix}, \quad \alpha_j = \begin{pmatrix} 0 & \sigma_j \\ \sigma_j & 0 \end{pmatrix}, \quad j = 1, 2, 3, \tag{1.2}
\]

where \( I_n \) is the \( n \times n \) identity matrix and \( \sigma_j \) \( (j = 1, 2, 3) \) are the Pauli matrices defined as:

\[
\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{1.3}
\]

In order to nondimensionalize the Dirac equation (1.1), we take

\[
\tilde{\mathbf{x}} = \frac{\mathbf{x}}{x_s}, \quad \tilde{t} = \frac{t}{t_s}, \quad \tilde{V} = \frac{V}{A_s}, \quad \tilde{\mathbf{A}} = \frac{\mathbf{A}}{A_s}, \quad \tilde{\Psi}(\tilde{t}, \tilde{\mathbf{x}}) = \frac{\Psi(\mathbf{r}, \mathbf{x})}{\psi_s}, \tag{1.4}
\]
where $x, t,$ and $m$ are length unit, time unit and mass unit, respectively, to be taken for the nondimensionalization of the Dirac equation (1.1). Plugging (1.4) into (1.1) and taking $\psi = x^{-3/2}$ and $A = \frac{m^2}{\hbar^2}$, after some simplification and then removing all $\tilde{}$, we obtain the dimensionless Dirac equation in 3D

$$i\delta \partial_t \Psi = \left( -\frac{\delta}{\epsilon} \sum_{j=1}^{3} \alpha_j \partial_j + \frac{\nu}{\epsilon^2} \beta \right) \Psi + \left( V(x) I_4 - \sum_{j=1}^{3} A_j(x) \alpha_j \right) \Psi, \quad x \in \mathbb{R}^3,$$  

(1.5)

where the three dimensionless parameters $0 < \epsilon, \delta, \nu \leq 1$ are given as

$$\epsilon = \frac{x_s}{t_s c}, \quad \delta = \frac{\bar{h} s}{m_s x_s^2}, \quad \nu = \frac{m}{m_s},$$

(1.6)

with $v_s = x_s/t_s$ the velocity unit for nondimensionalization. In fact, here $\epsilon$ represents the ratio between the wave velocity and the speed of light, i.e. it is inversely proportional to the speed of light, $\delta$ stands for the scaled Planck constant and $\nu$ is the ratio between the mass of the particle and the mass unit taken for the nondimensionalization.

As discussed in [9], under proper assumption on the electromagnetic potentials $V(x)$ and $A(x)$, the Dirac equation (1.5) in 3D could be reduced to two dimensions (2D) and one dimension (1D). Specifically, the Dirac equation in 2D has been widely applied to model the electron structure and dynamical properties of graphene and other 2D materials as they share the same dispersion relation on certain points called Dirac points [33, 34, 35, 48]. In fact, the Dirac equation (1.5) in 3D and its dimension reduction in 2D and 1D can be formulated in a unified way in $d$-dimensions ($d = 1, 2, 3$) as

$$i\delta \partial_t \Psi = \left( -\frac{\delta}{\epsilon} \sum_{j=1}^{d} \alpha_j \partial_j + \frac{\nu}{\epsilon^2} \beta \right) \Psi + \left( V(x) I_4 - \sum_{j=1}^{d} A_j(x) \alpha_j \right) \Psi, \quad x \in \mathbb{R}^d,$$  

(1.7)

where $x = (x_1, x_2)^T$ (or $x = (x, y)^T$) in 2D and $x = x_1$ (or $x = x$) in 1D. To study the dynamics of the Dirac equation (1.7), the initial condition is usually taken as

$$\Psi(t = 0, x) = \Psi_0(x), \quad x \in \mathbb{R}^d.$$  

(1.8)

The Dirac equation (1.7) with (1.8) is dispersive, time-symmetric, and it conserves the total probability [9]

$$\|\Psi(t, \cdot)\|^2 := \int_{\mathbb{R}^d} |\Psi(t, x)|^2 dx = \int_{\mathbb{R}^d} \sum_{j=1}^{d} |\psi_j(t, x)|^2 dx \equiv \|\Psi_0(\cdot)\|^2 = \|\Psi_0\|^2, \quad t \geq 0.$$  

(1.9)
and the energy \[ E(Ψ(t,·)) := \int_{\mathbb{R}^d} \left( -\frac{\delta}{\varepsilon} \sum_{j=1}^{d} Ψ^* α_j \partial_j Ψ + \frac{\nu}{\varepsilon^2} Ψ^* β Ψ + V(x)|Ψ|^2 - \sum_{j=1}^{d} A_j(x)Ψ^* α_j Ψ \right) dx \]
\begin{equation}
\equiv E(Ψ(t)), \quad t \geq 0, \tag{1.10}
\end{equation}
where \( Ψ^* = Ψ^T \) with \( T \) denoting the complex conjugate of \( f \).

Introduce the total probability density \( ρ := ρ(t,x) \) as
\begin{equation}
ρ(t,x) = \sum_{j=1}^{d} ρ_j(t,x) = Ψ(t,x)^*Ψ(t,x), \quad x \in \mathbb{R}^d, \tag{1.11}
\end{equation}
where the probability density \( ρ_j := ρ_j(t,x) \) of the \( j \)-th \((j = 1,2,3,4)\) component is defined as
\begin{equation}
ρ_j(t,x) = |Ψ_j(t,x)|^2, \quad x \in \mathbb{R}^d, \tag{1.12}
\end{equation}
and the current density \( J_l(t,x) = (J_1(t,x),...J_d(t,x))^T \) as
\begin{equation}
J_l(t,x) = \frac{1}{\varepsilon} Ψ(t,x)^* α_l Ψ(t,x), \quad l = 1,...,d, \tag{1.13}
\end{equation}
then the following conservation law can be obtained from the Dirac equation \((1.7)\) \[9\]
\begin{equation}
∂_t ρ(t,x) + \nabla \cdot J(t,x) = 0, \quad x \in \mathbb{R}^d, \quad t \geq 0. \tag{1.14}
\end{equation}

If the electric potential \( V \) is perturbed by a real constant \( V^0 \), i.e., \( V \rightarrow V + V^0 \), then the solution \( Ψ(t,x) \rightarrow e^{-i\omega t/V^0}Ψ(t,x) \), which implies that the probability density of each component \( ρ_j \) \((j = 1,2,3,4)\) and the total probability density \( ρ \) are all unchanged. In addition, when \( d = 1 \), if the magnetic potential \( A_1 \) is perturbed by a real constant \( A_1^0 \) i.e., \( A_1 \rightarrow A_1 + A_1^0 \), then the solution \( Ψ(t,x) \rightarrow e^{A_1^0 x^1}Ψ(t,x) \), which implies that only the total probability density \( ρ \) is unchanged; however, this property is unfortunately not valid in 2D and 3D. Furthermore, if the external electromagnetic potentials are all real constants, i.e. \( V(x) \equiv V^0 \) and \( A_j(x) \equiv A_j^0 \) \((j = 1,...,d)\) with \( A^0 = (A_1^0,...,A_d^0)^T \), the Dirac equation \((1.7)\) admits the plane wave solution \( Ψ(t,x) = B e^{i(k \cdot x - ω t)} \) with \( ω \) the time frequency. \( B \in \mathbb{R}^4 \) the amplitude vector and \( k = (k_1,...,k_d)^T \in \mathbb{R}^d \) the spatial wave number, which satisfies the following eigenvalue problem
\begin{equation}
ωB = \left( \sum_{j=1}^{d} \left( \frac{δk_j}{\varepsilon} - A_j^0 \right) α_j + \frac{V}{\varepsilon^2} β + V^0 I_d \right) B. \tag{1.15}
\end{equation}
Solving the above equation, we can get the dispersion relation of the Dirac equation \((1.7)\)
\begin{equation}
ω := ω(k) = V^0 \pm \frac{1}{\varepsilon^2} \sqrt{V^2 + δ^2 k^2 - ε A^0 k^2}, \quad k \in \mathbb{R}^d. \tag{1.16}
\end{equation}
In 2D and 1D, i.e., \( d = 2 \) or \( d = 1 \) in \([\text{1.1}]\), similar as those in \([\text{8}]\), the Dirac equation \((\text{1.1})\) can be decoupled into two simplified PDEs with 

\[
\Phi := \Phi(t, x) = (\psi_1(t, x), \psi_2(t, x))^T \in \mathbb{C}^2,
\]

satisfying

\[
i\hbar \partial_t \Phi = \left( -i \frac{\hbar}{\epsilon} \sum_{j=1}^{d} \sigma_j \partial_j + \frac{\epsilon}{\hbar^2} \sigma_3 \right) \Phi + \left( V(x) I_2 - \sum_{j=1}^{d} A_j(x) \sigma_j \right) \Phi, \quad x \in \mathbb{R}^d, \quad (\text{1.17})
\]

where \( \Phi = (\psi_1, \psi_2)^T \) (or \( \Phi = (\psi_2, \psi_3)^T \)). Again, to study the dynamics of the Dirac equation \((\text{1.17})\), the initial condition is usually taken as

\[
\Phi(t = 0, x) = \Phi_0(x), \quad x \in \mathbb{R}^d. \quad (\text{1.18})
\]

Similarly, the Dirac equation \((\text{1.17})\) with \((\text{1.18})\) is dispersive, time-symmetric, and it conserves the total probability \([\text{9}]\)

\[
\| \Phi(t, \cdot) \|^2 := \int_{\mathbb{R}^d} |\Phi(t, x)|^2 \, dx = \int_{\mathbb{R}^d} \sum_{j=1}^{2} |\phi_j(t, x)|^2 \, dx \nonumber
\]

\[
\equiv \| \Phi(0, \cdot) \|^2 = \| \Phi_0 \|^2, \quad t \geq 0, \quad (\text{1.19})
\]

and the energy \([\text{9}]\)

\[
E(\Phi(t, \cdot)) := \int_{\mathbb{R}^d} \left( -\frac{\hbar}{\epsilon} \sum_{j=1}^{d} \Phi^* \sigma_j \partial_j \Phi + \frac{\epsilon}{\hbar^2} \Phi^* \sigma_3 \Phi + V(x) |\Phi|^2 - \sum_{j=1}^{d} A_j(x) \Phi^* \sigma_j \Phi \right) \, dx \nonumber
\]

\[
\equiv E(\Phi_0), \quad t \geq 0. \quad (\text{1.20})
\]

Again, introduce the total probability density \( \rho := \rho(t, x) \) as

\[
\rho(t, x) = \sum_{j=1}^{2} \rho_j(t, x) = \Phi(t, x)^* \Phi(t, x), \quad x \in \mathbb{R}^d, \quad (\text{1.21})
\]

where the probability density \( \rho_j := \rho_j(t, x) \) of the \( j \)-th \( (j = 1, 2) \) component is defined as

\[
\rho_j(t, x) = |\phi_j(t, x)|^2, \quad x \in \mathbb{R}^d, \quad (\text{1.22})
\]

and the current density \( J_l(t, x) = (J_1(t, x), \ldots, J_d(t, x))^T \) as

\[
J_l(t, x) = \frac{1}{\hbar} \Phi(t, x)^* \sigma_l \Phi(t, x), \quad l = 1, \ldots, d, \quad (\text{1.23})
\]

then the same conservation law \((\text{1.14})\) can be obtained from the Dirac equation \((\text{1.17})\) \([\text{9}]\).

Similarly, if the electric potential \( V \) is perturbed by a real constant \( V^0 \), i.e., \( V \to V + V^0 \), then the solution \( \Phi(t, x) \to e^{-i \frac{\hbar}{\epsilon} V^0 t} \Phi(t, x) \), which implies that the probability density of each component \( \rho_j (j = 1, 2) \) and the total probability density \( \rho \) are all unchanged. In addition, when \( d = 1 \), if the magnetic potential \( A_1 \) is perturbed by a real constant \( A_1^0 \), i.e.,
A1 → A1 + A1^0, then the solution \( \Phi(t, x) \rightarrow e^{iA1^0t} \Phi(t, x) \), which implies that only the total probability density \( \rho \) is unchanged; however, this property is unfortunately not valid in 2D. Furthermore, if the external electromagnetic potentials are all real constants, i.e. \( V(x) \equiv V^0 \) and \( A_j(x) \equiv A_j^0 (j = 1, \ldots, d) \) with \( A^0 = (A_1^0, \ldots, A_d^0)^T \), the Dirac equation \( \ref{eq:1.1} \) admits the plane wave solution \( \Phi(t, x) = B e^{i(kx - \omega t)} \) with \( \omega \) the time frequency, \( B \in \mathbb{R}^2 \) the amplitude vector and \( k = (k_1, ..., k_d)^T \in \mathbb{R}^d \) the spatial wave number, which satisfies the following eigenvalue problem

\[
\omega B = \left( \sum_{j=1}^{d} \left( \frac{\delta k_j}{\varepsilon} - A_j^0 \right) \sigma_j + \frac{V}{\varepsilon^2} \sigma_3 + V^0 \sigma_2 \right) B.
\] (1.24)

Solving the above equation, we can get the dispersion relation of the Dirac equation \( \ref{eq:1.1} \)

\[
\omega := \omega(k) = V^0 \pm \frac{1}{\varepsilon} \sqrt{\varepsilon^2 + \varepsilon^2 |\delta k - \varepsilon A^0|^2}, \quad k \in \mathbb{R}^d.
\] (1.25)

If one sets the mass unit \( m_1 = m \), length unit \( x_1 = \frac{h}{mc} \), and time unit \( t_s = \frac{\hbar}{mc^2} \), then \( \varepsilon = \delta = \nu = 1 \), which corresponds to the classical (or standard) scaling. This choice of \( x_1, m_1 \) and \( t_s \) is appropriate when the wave speed is at the same order of the speed of light. However, a different choice of \( x_s, m_s \) and \( t_s \) is more appropriate when the wave speed is much smaller than the speed of light. We remark here that the choice of \( x_s, m_s \) and \( t_s \) determines the observation scale of time evolution of the system and decides which phenomena can be resolved by discretization on specified spatial/temporal grids and which phenomena is visible by asymptotic analysis.

Different parameter regimes could be considered for the Dirac equation \( \ref{eq:1.1} \) (or \( \ref{eq:1.17} \)), which are displayed in Fig. [1.1]

- Standard (or classical) regime, i.e. \( \varepsilon = \delta = \nu = 1 \) (\( \iff m_s = m \), \( x_s = \frac{h}{mc} \), and \( t_s = \frac{\hbar}{mc^2} \)), the wave speed is at the order of the speed of light. In this parameter regime, formally the dispersion relation \( \ref{eq:1.16} \) (or \( \ref{eq:1.25} \)) suggests \( \omega(k) = O(1) \) when \( |k| = O(1) \) and thus the solution propagates waves with wavelength at \( O(1) \) in space and time. In addition, if the initial data \( \Psi_0 = O(1) \) in \( \ref{eq:1.3} \) (or \( \Phi_0 = O(1) \) in \( \ref{eq:1.18} \)), then the solution \( \Psi = O(1) \) of \( \ref{eq:1.7} \) with \( \Phi = O(1) \) of \( \ref{eq:1.17} \) with \( \ref{eq:1.18} \)), which implies that the probability density \( \rho = O(1) \) in \( \ref{eq:1.11} \) (or \( \ref{eq:1.21} \)), current density \( J = O(1) \) in \( \ref{eq:1.13} \) (or \( \ref{eq:1.23} \)) and the energy \( E(\Psi(t, \cdot)) = O(1) \) in \( \ref{eq:1.10} \) (or \( E(\Phi(t, \cdot)) = O(1) \) in \( \ref{eq:1.29} \)). There were extensive analytical and numerical studies for the Dirac equation \( \ref{eq:1.7} \) (or \( \ref{eq:1.17} \)) with \( \varepsilon = \delta = \nu = 1 \) in the literatures. For the existence and multiplicity of bound states and/or standing wave solutions, we refer to [26, 27, 32, 40, 41, 52] and references therein. In this parameter regime, for the numerical part, many efficient and accurate numerical methods have been proposed and analyzed [3], such as the finite difference time domain (FDTD) methods [4, 50], time-splitting Fourier pseudospectral
A fourth-order compact time-splitting Fourier pseudospectral method for the Dirac equation

\[ \text{Dirac Eq. (1.7) (or (1.17)) with } \varepsilon, \delta, \nu \]

- Massless limit regime, i.e. \( \varepsilon = \delta = 1 \) and \( 0 < \nu \ll 1 \) (\( \Leftrightarrow x_s = \frac{\hbar}{m_\nu} \) and \( t_s = \frac{\hbar}{m_\nu} \)), the mass of the particle is much less than the mass unit. In this parameter regime, the Dirac equation (1.7) (or (1.17)) converges – regularly – to the Weyl equation \[51, 63\] with linear convergence rate in terms of \( \nu \). Any numerical methods for the Dirac equation (1.7) (or (1.17)) in the standard regime can be applied in this parameter regime.

- Nonrelativistic limit regime, i.e. \( \delta = \nu = 1 \) and \( 0 < \varepsilon \ll 1 \) (\( \Leftrightarrow m_s = m \) and \( t_s = \frac{m_\nu^2}{\hbar} \)), i.e. the wave speed is much less than the speed of light. In this parameter regime, formally the dispersion relation (1.16) (or (1.25)) suggests \( \omega(k) = \varepsilon^2 + O(1) \) when \( |k| = O(1) \) and thus the solution propagates waves with wavelength at \( O(\varepsilon^2) \) and \( O(1) \) in time and space, respectively, when \( 0 < \varepsilon \ll 1 \). In addition, if the initial data \( \Psi_0 = O(1) \) in (1.8) (or \( \Phi_0 = O(1) \) in (1.18)), then the solution \( \Psi = O(1) \) of (1.7) with \( \Phi = O(1) \) of (1.17) with (1.18), which implies that the probability density \( \rho = O(1) \) in (1.11) (or (1.21)), current density \( J = O(\varepsilon^{-1}) \) in (1.13) (or (1.23)) and the energy \( E(\Psi(t,\cdot)) = O(\varepsilon^{-2}) \) in (1.10) (or \( E(\Phi(t,\cdot)) = O(\varepsilon^{-2}) \) in (1.20)). The highly oscillatory nature of the solution in time and the unboundedness of the energy bring significant difficulty in mathematical analysis and numerical simulation of the Dirac equation in the nonrelativistic regime, i.e. \( 0 < \varepsilon \ll 1 \). By diagonalizing the Dirac operator and using proper ansatz, one can show that the Dirac equation (1.7) (or (1.17)) converges –

\( (TSFP) \) method [9, 42, 20], exponential wave integrator Fourier pseudospectral (EWI- FP) method [9], the Gaussian beam method [62], etc.
Semiclassical limit regime, i.e. $\varepsilon = 1$ and $0 < \delta \ll 1$ ($\leftrightarrow m_c = m$ and $t_c = \frac{m_c}{\varepsilon}$), the quantum effect could be neglected. In this parameter regime, the solution propagates waves with wavelength at $O(\delta)$ in space and time $[18]$ when $0 < \delta \ll 1$. In addition, if the initial data $\Psi_0 = O(1)$ in (1.8) (or $\Phi_0 = O(1)$ in (1.18)), then the solution $\Psi = O(1)$ of (1.7) with (1.8), (or $\Phi = O(1)$ of (1.17) with (1.18)), which implies that the probability density $\rho = O(1)$ in (1.11) (or (1.21)), current density $J = O(1)$ in (1.13) (or (1.23)) and the energy $E(\Psi(t, \cdot)) = O(1)$ in (1.10) (or $E(\Phi(t, \cdot)) = O(1)$ in (1.20)). The highly oscillatory nature of the solution in time and space brings significant difficulty in mathematical analysis and numerical simulation of the Dirac equation in the semiclassical limit regime, i.e. $0 < \delta \ll 1$. By using the Wigner transformation method, one can show that the Dirac equation (1.7) (or (1.17)) converges – singularly – to the relativistic Euler equations [31, 39, 53]. Similar to the analysis of different numerical methods for the Schrödinger equation in the semiclassical limit regime [24, 31, 12, 21, 22, 45], it is an interesting question to establish rigorous error bounds of different numerical methods for the Dirac equation in the semiclassical limit regime such that they depend explicitly on mesh size $h$, time step $\tau$ as well as the small parameter $\delta \in (0, 1)$.

Simultaneously nonrelativistic and massless limit regimes, i.e. $\delta = 1$, $\nu \sim \varepsilon$ and $0 < \varepsilon \ll 1$ ($\leftrightarrow t_c = \frac{m_c^2}{\varepsilon}$), the wave speed is much less than the speed of light and the mass of the particle is much less than the mass unit. Here we assume $\nu = \nu_0 \varepsilon$ with $\nu_0 > 0$ a constant independent of $\varepsilon \in (0, 1]$. In this case, the Dirac equation (1.7) can be re-written as $(d = 1, 2, 3)$

$$i\partial_t \Psi = \left(-i\frac{1}{\varepsilon} \sum_{j=1}^{d} \sigma_j \partial_j + \frac{\nu_0}{\varepsilon} \beta \right) \Psi + \left(V(x)I_4 - \sum_{j=1}^{d} A_j(x) \sigma_j \right) \Psi, \quad x \in \mathbb{R}^d, \quad (1.26)$$

and respectively, the Dirac equation (1.17) can be re-written as $(d = 1, 2)$

$$i\partial_t \Phi = \left(-i\frac{1}{\varepsilon} \sum_{j=1}^{d} \sigma_j \partial_j + \frac{\nu_0}{\varepsilon} \sigma_3 \right) \Phi + \left(V(x)I_2 - \sum_{j=1}^{d} A_j(x) \sigma_j \right) \Phi, \quad x \in \mathbb{R}^d. \quad (1.27)$$

In this parameter regime, formally the dispersion relation (1.16) (or (1.25)) suggests $\omega(k) = O(\varepsilon^{-1})$ when $|k|$ is of $O(1)$ and thus the solution propagates waves with wavelength at $O(\varepsilon)$ and $O(1)$ in time and space, respectively, when $0 < \varepsilon \ll 1$. In addition, if the initial data $\Psi_0 = O(1)$ in (1.8) (or $\Phi_0 = O(1)$ in (1.18)), then the solution $\Psi = O(1)$ of (1.26) with (1.8) (or $\Phi = O(1)$ of (1.27) with (1.18), which implies that the proba-
bility density \( \rho = O(1) \) in (1.11) (or (1.21)), current density \( J = O(\varepsilon^{-1}) \) in (1.13) (or (1.23)) and the energy \( E(\Psi(t, \cdot)) = O(\varepsilon^{-1}) \) in (1.10) (or (1.20)).

Again, the highly oscillatory nature of the solution in time and the unboundedness of the energy bring significant difficulty in mathematical analysis and numerical simulation of the Dirac equation in this parameter regime. In fact, it is an interesting question to study the singular limit of the Dirac equation (1.26) (or (1.27)) when \( \varepsilon \to 0^+ \) and establish rigorous error bounds of different numerical methods for the Dirac equation in this parameter regime such that they depend explicitly on mesh size \( h \), time step \( \tau \) as well as the small parameter \( \varepsilon \in (0, 1] \).

First-order and second-order (in time) time-splitting spectral methods have been proposed and analyzed for the Dirac equation (1.7) (or (1.17)) [9]. Extension to higher order, e.g. fourth-order, time-splitting spectral methods can be done straightforward by adapting the high order splitting methods [14, 47, 57], e.g. the standard fourth-order splitting (\( S_4 \)) [37, 55, 64] or the fourth-order partitioned Runge-Kutta (\( S_{4RK} \)) splitting method [16, 38]. As it was observed in the literature [47], the \( S_4 \) splitting method has to use negative time step in at least one of the sub-problems at each time interval [37, 55, 64], which causes some kind of drawbacks in practical computation, and the number of sub-problems in the \( S_{4RK} \) splitting method at each time interval is much bigger than that of the \( S_4 \) splitting method [16], which increases the computational cost at each time step a lot. Motivated by the fourth-order gradient symplectic integrator for the Schrödinger equation invented by [23, 24, 25], a new fourth-order compact time-splitting (\( S_{4c} \)) Fourier pseudospectral method will be proposed for the Dirac equation by splitting the Dirac equation into two parts together with using the double commutator between them to integrate the Dirac equation at each time interval. The method is explicit, fourth-order in time and spectral order in space. We compare the accuracy and efficiency as well as long time behavior of the \( S_{4c} \) method with many other existing time-splitting methods for the Dirac equation. Numerical results demonstrate the advantage of the proposed \( S_{4c} \) in terms of efficiency and accuracy, especially in 1D and high dimensions (2D and 3D) without magnetic potential. We also report the spatial/temporal resolution of the \( S_{4c} \) method for the Dirac equation in different parameter regimes.

The rest of the paper is organized as follows. In section 2, we review different time-splitting schemes for differential equations. In section 3, we calculate the double commutator between the two parts decoupled from the Dirac equation. A fourth-order compact time-splitting Fourier pseudospectral method is proposed for the Dirac equation in section 4. In section 5, we compare accuracy and efficiency as well as long time behavior of different time-splitting methods for the Dirac equation. In section 6, we report spatial/temporal resolution of the fourth-order compact time-splitting Fourier pseudospectral method for the Dirac equation in different parameter regimes. Finally, some concluding remarks are drawn in section 7. Throughout the paper, we adopt the standard Sobolev spaces and the corre-
sponding norms and adopt $A \lesssim B$ to mean that there exists a generic constant $C > 0$ independent of $\varepsilon, \tau, h, \delta$ and $v$ such that $|A| \leq CB$.

2 Review of different time-splitting schemes

Splitting (or split-step or time-splitting) methods have been widely used in numerically integrating differential equations \[47\]. Combined with different spatial discretization schemes, they have also been applied in solving partial differential equations \[47\]. For details, we refer to \[56, 57, 58\] and references therein.

For simplicity of notations and the convenience of readers, here we review several time-splitting schemes for integrating a differential equation in the form

$$\partial_t u(t, x) = (T + W)u(t, x),$$

(2.1)

with the initial data

$$u(0, x) = u_0(x),$$

(2.2)

where $T$ and $W$ are two time-independent operators. For any time step $\tau > 0$, formally the solution of (2.1) with (2.2) can be represented as

$$u(\tau, x) = e^{\tau(T+W)}u_0(x).$$

(2.3)

A splitting (or split-step or time-splitting) scheme can be designed by approximating the operator $e^{\tau(T+W)}$ by a product of a sequence of $e^{\tau T}$ and $e^{\tau W}$ \[55, 64\], i.e.

$$e^{\tau(T+W)} \approx \prod_{j=1}^{n} e^{a_j \tau T} e^{b_j \tau W},$$

(2.4)

where $n \geq 1$, $a_j \in \mathbb{R}$ and $b_j \in \mathbb{R}$ ($j = 1, \ldots, n$) are to be determined such that the approximation has certain order of accuracy in terms of $\tau$ \[55, 64\]. Without loss of generality, here we suppose that the computation for $e^{\tau W}$ is easier and/or more efficient than that for $e^{\tau T}$.

2.1 First-order and second-order time-splitting methods

Taking $n = 1$ and $a_1 = b_1 = 1$ in (2.4), one can obtain the first-order Lie-Trotter splitting ($S_1$) method as \[61\]

$$u(\tau, x) \approx S_1(\tau)u_0(x) := e^{\tau T} e^{\tau W}u_0(x).$$

(2.5)

In this method, one needs to integrate the operator $T$ once and the operator $W$ once. By using Taylor expansion, one can formally show the local truncation error as \[54\]

$$\|u(\tau, x) - S_1(\tau)u_0(x)\| \leq C_1 \tau^2,$$

(2.6)
where $C_1 > 0$ is a constant independent of $\tau$ and $\| \cdot \|$ is a norm depending on the problem. Thus the method is formally a first-order integrator [47].

Similarly, taking $n = 2$, $a_1 = 0$, $b_1 = \frac{1}{2}$, $a_2 = 1$ and $b_2 = \frac{1}{2}$, one can obtain the second-order Strang splitting ($S_2$) method as [54]

$$u(\tau, x) \approx S_2(\tau)u_0(x) := e^{\tau W} e^{\tau T} e^{\tau W} u_0(x).$$

(2.7)

In this method, one needs to integrate the operator $T$ once and the operator $W$ twice. Again, by using Taylor expansion, one can formally show the local truncation error as [54]

$$\| u(\tau, x) - S_2(\tau)u_0(x) \| \leq C_2\tau^3,$$

(2.8)

where $C_2 > 0$ is a constant independent of $\tau$. Thus it is formally a second-order integrator [47].

2.2 Fourth-order time-splitting methods

High order, especially fourth-order, splitting methods for (2.1) with (2.2) via the construction (2.4) had been extensively studied in the literature [23, 24].

For simplicity, here we only mention a popular fourth-order Forest-Ruth (or Yoshida) splitting ($S_4$) method [37, 55, 64] as

$$u(\tau, x) \approx S_4(\tau)u_0(x) := S_2(w_1 \tau)S_2(w_2 \tau)S_2(w_1 \tau)u_0(x),$$

(2.9)

where

$$w_1 = \frac{1}{2} - \frac{1}{2^{1/3}}, \quad w_2 = -\frac{2^{1/3}}{2 - 2^{1/3}}.$$  \hspace{1cm} (2.10)

In this method, one needs to integrate the operator $T$ three times and the operator $W$ four times. Again, by using Taylor expansion, one can formally show the local truncation error as [37]

$$\| u(\tau, x) - S_4(\tau)u_0(x) \| \leq C_4\tau^5,$$

(2.11)

where $C_4 > 0$ is a constant independent of $\tau$. Thus it is formally a fourth-order integrator [47]. Due to that negative time steps, e.g. $w_2 < 0$, are used in the method, in general, it cannot be applied to solve dissipative differential equations. In addition, as it was noticed in the literature [47], some drawbacks of the $S_4$ method were reported, such as the constant $C_4$ is usually much larger than $C_1$ and $C_2$, and the fourth-order accuracy could be observed only when $\tau$ is very small [47, 58].
To overcome the drawbacks of the $S_4$ method, the fourth-order partitioned Runge-Kutta splitting ($S_{4\text{RK}}$) method was proposed \[16,38\] as

$$u(\tau, x) \approx S_{4\text{RK}}(\tau)u_0(x)$$

(2.12)

$$:= e^{\alpha_1 \tau W} e^{\alpha_2 \tau T} e^{\alpha_3 \tau W} e^{\alpha_4 \tau T} e^{\alpha_5 \tau W} e^{\alpha_6 \tau T} e^{\alpha_7 \tau W} u_0(x),$$

where

$$a_1 = 0.0792036964311957, \quad a_2 = 0.353172906049774, \quad a_3 = -0.0420650803577195, \quad a_4 = 1 - \frac{1}{2}(a_1 + a_2 + a_3),$$

$$b_1 = 0.209515106613362, \quad b_2 = -0.143851773179818, \quad b_3 = \frac{1}{2} - (b_1 + b_2).$$

In this method, one needs to integrate the operator $T$ six times and the operator $W$ seven times. Again, by using Taylor expansion, one can formally show the local truncation error as \[16\]

$$\|u(\tau, x) - S_{4\text{RK}}(\tau)u_0(x)\| \leq \tilde{C}_4 \tau^5,$$

(2.13)

where $\tilde{C}_4 > 0$ is a constant independent of $\tau$. Thus it is formally a fourth-order integrator \[47\]. It is easy to see that the computational cost of the $S_{4\text{RK}}$ method is about two times that of the $S_4$ method. In this method, negative time steps, e.g. $a_3 < 0$, have also been used.

### 2.3 Fourth-order compact time-splitting methods

To avoid the negative time steps and motivated by the numerical integration of the Schrödinger equation \[23,24,25\], a fourth-order gradient symplectic integrator was proposed by S. A. Chin \[23\] as

$$u(\tau, x) \approx S_{4c}(\tau)u_0(x)$$

(2.14)

$$:= e^{\frac{1}{6} \tau \tilde{W}} e^{\frac{1}{2} \tau T} e^{\frac{1}{4} \tau W} e^{\frac{1}{4} \tau T} e^{\frac{1}{2} \tau W} u_0(x),$$

where

$$\tilde{W} := W + \frac{1}{48} \tau^2 [W, [T, W]],$$

(2.15)

with $[T, W] := TW - WT$ the commutator of the two operators $T$ and $W$ and $[W, [T, W]]$ a double commutator. Again, by using Taylor expansion, one can formally show the local truncation error as \[23,24\]

$$\|u(\tau, x) - S_{4c}(\tau)u_0(x)\| \leq \hat{C}_4 \tau^5,$$

(2.16)

where $\hat{C}_4 > 0$ is a constant independent of $\tau$. Thus it is formally a fourth-order integrator \[47\]. In this method, in general, one needs to integrate the operator $T$ twice and the operator $W$ three times under the assumption that the computation of $\tilde{W}$ is equivalent to that of $W$. 
Thus it is more efficient than the \(S_4\) and \(S_{4RK}\) methods. In this sense, it is more appropriate to name it as a \textbf{fourth-order compact splitting} \((S_{4c})\) method since, at each time step, the number of sub-steps in it is much less than those in the \(S_4\) and \(S_{4RK}\) methods. Another advantage of the \(S_{4c}\) method is that there is no negative time step in it.

For comparison, Table 2.1 lists the numbers of \(T\) and \(W\) to be integrated by different splitting methods. From it, under the assumption that the computation for \(e^{\tau T}\) is easier and/or more efficient than that for \(e^{\tau T}\) and the computation of \(e^{\tau \hat{W}}\) is similar to that for \(e^{\tau W}\), we could draw the following conclusions: (i) the computational time of \(S_2\) is almost the same as that of \(S_1\); (ii) the computational time of \(S_{4c}\) is about two times of that of \(S_2\) (or \(S_1\)); (iii) among the three fourth-order splitting methods, \(S_{4c}\) is the most efficient and \(S_{4RK}\) is the most expensive.

3 Computation for the double commutator \([W, [T, W]]\)

In this section, we first show that the double commutator \([W, [T, W]]\) is linear in \(T\) and then compute it for the Dirac equations (1.17) for \(d = 1, 2\) and (1.7) for \(d = 1, 2, 3\).

**Lemma 1** Let \(T\) and \(W\) be two operators, then we have

\[
[W, [T, W]] = 2WTW - WWT - TWW. \tag{3.1}
\]

Thus the double commutator \([W, [T, W]]\) is linear in \(T\), i.e. for any two operators \(T_1\) and \(T_2\), we have

\[
[W, [a_1T_1 + a_2T_2, W]] = a_1[W, [T_1, W]] + a_2[W, [T_2, W]], \quad a_1, a_2 \in \mathbb{R}. \tag{3.2}
\]

**Proof** Noticing \([T, W] := TW - WT\), we have

\[
[W, [T, W]] = [W, (TW - WT)] = W(TW - WT) - (TW - WT)W = WTW - WWT - TWW + WTW = 2WTW - WWT - TWW. \tag{3.3}
\]

From (3.3), it is easy to see that the double commutator \([W, [T, W]]\) is linear in \(T\), i.e. (3.2) is valid.

| \(S_1\) | \(S_2\) | \(S_4\) | \(S_{4RK}\) | \(S_{4c}\) |
|---|---|---|---|---|
| \(T\) | 1 | 1 | 3 | 6 | 2 |
| \(W\) | 1 | 2 | 4 | 7 | 3 |

Table 2.1 The numbers of operators \(T\) and \(W\) to be implemented in different time-splitting methods.
3.1 Double commutators of the Dirac equation in 1D

**Lemma 2** For the Dirac equation (1.17) in 1D, i.e. $d = 1$, define

\[ T = \frac{1}{\varepsilon} \sigma_1 \partial_1 - \frac{iV}{\delta \varepsilon} \sigma_3, \quad W = \frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right), \tag{3.4} \]

we have

\[ \left[ W, [T, W] \right] = -\frac{4iV}{\delta^2 \varepsilon^2} A_1^2(x) \sigma_3. \tag{3.5} \]

**Proof** Combining (3.4) and (3.2), we obtain

\[ \left[ W, [T, W] \right] = -\frac{1}{\varepsilon} \left[ W, [\sigma_1 \partial_1, W] \right] - \frac{iV}{\delta \varepsilon^2} \left[ W, [\sigma_3, W] \right]. \tag{3.6} \]

Noticing (3.1) and (3.4), we have

\[
\begin{align*}
\left[ W, [\sigma_1 \partial_1, W] \right] &= 2 \left( -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \right) (\sigma_1 \partial_1) \left( -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \right) \\
&\quad - \left( -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \right)^2 (\sigma_1 \partial_1) - (\sigma_1 \partial_1) \left( -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \right)^2 \\
&= -\frac{2}{\delta^2} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \sigma_1 \partial_1 (V(x) I_2 - A_1(x) \sigma_1) \\
&\quad + \frac{1}{\delta^2} \left( V(x) I_2 - A_1(x) \sigma_1 \right)^2 \sigma_1 \partial_1 + \frac{1}{\delta^2} \sigma_1 \partial_1 (V(x) I_2 - A_1(x) \sigma_1)^2 \\
&= -\frac{2}{\delta^2} \sigma_1 (V(x) I_2 - A_1(x) \sigma_1) \partial_1 (V(x) I_2 - A_1(x) \sigma_1) \\
&\quad + \frac{2}{\delta^2} \sigma_1 (V(x) I_2 - A_1(x) \sigma_1) \partial_1 (V(x) I_2 - A_1(x) \sigma_1)^2 \\
&\quad + \frac{2}{\delta^2} \sigma_1 (V(x) I_2 - A_1(x) \sigma_1) \partial_1 (V(x) I_2 - A_1(x) \sigma_1)^2 \\
&= 0. \tag{3.7}
\end{align*}
\]

\[
\begin{align*}
\left[ W, [\sigma_3, W] \right] &= 2 \left( -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \right) \sigma_3 \left( -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \right) \\
&\quad - \left( -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \right)^2 \sigma_3 - \sigma_3 \left( -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \right)^2 \\
&= -\frac{2}{\delta^2} \left( V(x) I_2 - A_1(x) \sigma_1 \right) \left( V(x) I_2 + A_1(x) \sigma_1 \right) \sigma_3 + \frac{1}{\delta^2} \left( V(x) I_2 - A_1(x) \sigma_1 \right)^2 \sigma_3 \\
&\quad + \frac{1}{\delta^2} \left( V(x) I_2 + A_1(x) \sigma_1 \right)^2 \sigma_3 \\
&= -\frac{1}{\delta^2} \left( 2V^2(x) I_2 - 2A_1^2(x) I_2 - (V^2(x) I_2 + A_1^2(x) I_2) - 2A_1(x) V(x) \sigma_1 \right) \sigma_3 \\
&\quad + \left( V^2(x) I_2 + A_1^2(x) I_2 + 2A_1(x) V(x) \sigma_1 \right) \sigma_3 \\
&= -\frac{1}{\delta^2} \left( 4A_1^2(x) I_2 \right) \sigma_3 + \frac{4}{\delta^2} A_1^2(x) \sigma_3. \tag{3.8}
\end{align*}
\]
Corollary 1 For the Dirac equation (1.1) in 1D, i.e. $d=1$, define
\[ T = -\frac{1}{\epsilon} \partial_1 \sigma_1 - \frac{iv}{\delta \epsilon^2} \beta, \quad W = -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 \right), \] (3.10)
we have
\[ [W, [T, W]] = -\frac{4iv}{\delta^2 \epsilon^2} A_1^2(x) \beta. \] (3.11)

3.2 Double commutators of the Dirac equation in 2D and 3D

Similar to the 1D case, we have (see detailed computation in Appendix A)

Lemma 3 For the Dirac equation (1.1) in 2D, i.e. $d=2$, define
\[ T = -\frac{1}{\epsilon} \sigma_1 \partial_1 - \frac{1}{\epsilon} \sigma_2 \partial_2 - \frac{iv}{\delta \epsilon^2} \sigma_3, \quad W = -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 - A_2(x) \sigma_2 \right), \] (3.12)
we have
\[ [W, [T, W]] = F_3(x) + F_1(x) \partial_1 + F_2(x) \partial_2. \] (3.13)

where
\[ F_1(x) = \frac{4}{\delta^2 \epsilon^2} \left( -A_1^2(x) \sigma_1 + A_1(x) A_2(x) \sigma_2 \right), \quad F_2(x) = \frac{4}{\delta^2 \epsilon^2} \left( A_1(x) A_2(x) \sigma_1 - A_1^2(x) \sigma_2 \right), \]
\[ F_3(x) = \frac{4}{\delta^2 \epsilon^2} \left( A_1(x) \sigma_1 A_2(x) - A_2(x) \sigma_1 A_1(x) \right) \sigma_2 + \frac{4}{\delta^2 \epsilon^2} \left( A_2(x) \sigma_1 V(x) - A_1(x) \sigma_2 V(x) - \frac{v}{\delta} \left( A_1^2(x) + A_2^2(x) \right) \right) \sigma_3. \]

Corollary 2 For the Dirac equation (1.1) in 2D, i.e. $d=2$, define
\[ T = -\frac{1}{\epsilon} \sigma_1 \partial_1 - \frac{1}{\epsilon} \sigma_2 \partial_2 - \frac{iv}{\delta \epsilon^2} \beta, \quad W = -\frac{i}{\delta} \left( V(x) I_2 - A_1(x) \sigma_1 - A_2(x) \sigma_2 \right), \] (3.14)
we have
\[ [W, [T, W]] = F_3(x) + F_1(x) \partial_1 + F_2(x) \partial_2. \] (3.15)
where

\[ F_1(x) = \frac{4}{\delta^2 \epsilon} \left( -A_2(x) A_1(x) + A_1(x) A_2(x) \right), \quad F_2(x) = \frac{4}{\delta^2 \epsilon} \left( A_1(x) A_2(x) A_1(x) - A_1(x) A_2(x) \right). \]

\[ F_3(x) = \frac{4}{\delta^2 \epsilon} \left( A_1(x) \partial_2 A_2(x) - A_2(x) \partial_1 A_1(x) \right) \alpha + \frac{4}{\delta^2 \epsilon} \left( A_2(x) \partial_1 A_2(x) - A_1(x) \partial_2 A_1(x) \right) \beta \]
\[ + \frac{4i}{\delta^2 \epsilon} \left( A_2(x) \partial_1 V(x) - A_1(x) \partial_2 V(x) \right) \gamma \alpha_3 - \frac{4iV}{\delta^2 \epsilon^2} \left( A_1(x) A_2(x) \right) \beta, \]

where

\[ \gamma = \begin{pmatrix} 0 & I_2 & 0 \\ I_2 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}. \] (3.16)

For the Dirac equation \( \mathbf{(4.1)} \) in 3D, i.e. \( d = 3 \), we have (see detailed computation in Appendix B)

**Lemma 4** For the Dirac equation \( \mathbf{(4.1)} \) in 3D, i.e. \( d = 3 \), define

\[ T = -\frac{1}{\epsilon} \sum_{j=1}^{3} \alpha_j \beta_j - \frac{iV}{\delta \epsilon^2} \beta, \quad W = -\frac{i}{\delta} \left( V(x) \beta - \sum_{j=1}^{3} A_j(x) \alpha_j \right), \] (3.17)

we have

\[ [W, [T, W]] = F_2(x) + F_1(x) \partial_1 + F_2(x) \partial_2 + F_3(x) \partial_3. \] (3.18)

where

\[ F_1(x) = \frac{4}{\delta^2 \epsilon} \left( -A_2(x) A_1(x) + A_1(x) A_2(x) \right) \alpha + A_1(x) A_2(x) \alpha_1 + A_1(x) A_3(x) \alpha_3, \]

\[ F_2(x) = \frac{4}{\delta^2 \epsilon} \left( A_2(x) A_1(x) \alpha_1 - A_1(x) A_2(x) \alpha_2 + A_2(x) A_3(x) \alpha_3 \right), \]

\[ F_3(x) = \frac{4}{\delta^2 \epsilon} \left( A_3(x) A_1(x) \alpha_1 + A_3(x) A_2(x) \alpha_2 - A_1(x) A_2(x) \alpha_3 \right), \]

\[ F_4(x) = \frac{4}{\delta^2 \epsilon} \left( A_1(x) \left( 2 \partial_2 A_2(x) + \partial_1 A_3(x) \right) - A_2(x) \partial_1 A_2(x) - A_3(x) \partial_1 A_3(x) \right) \alpha_1 \]
\[ + \frac{4}{\delta^2 \epsilon} \left( A_2(x) \left( \partial_1 A_1(x) + \partial_2 A_3(x) \right) - A_1(x) \partial_2 A_1(x) - A_3(x) \partial_3 A_3(x) \right) \alpha_2 \]
\[ + \frac{4}{\delta^2 \epsilon} \left( A_3(x) \left( \partial_1 A_1(x) + \partial_2 A_2(x) \right) - A_1(x) \partial_1 A_1(x) - A_2(x) \partial_2 A_2(x) \right) \alpha_3 \]
\[ + \frac{4i}{\delta^2 \epsilon} \left( A_1(x) \left( \partial_2 A_1(x) - \partial_3 A_2(x) \right) + A_2(x) \left( \partial_1 A_1(x) - \partial_3 A_3(x) \right) \right) \gamma \alpha_3 + \frac{4i}{\delta^2 \epsilon} \left( A_2(x) \partial_1 V(x) - A_1(x) \partial_2 V(x) \right) \gamma \alpha_2 \]
\[ + \frac{4i}{\delta^2 \epsilon} \left( A_2(x) \partial_1 V(x) - A_1(x) \partial_2 V(x) \right) \gamma \alpha_2 - \frac{4iV}{\delta^2 \epsilon^2} \left( A_1(x) A_2(x) \right) \beta. \]

From Lemmas \( \mathbf{3.3} \) and \( \mathbf{3.4} \) and Corollaries \( \mathbf{1.1} \) and \( \mathbf{1.2} \) it is easy to observe that the double commutator will vanish when the Dirac equation \( \mathbf{(4.17)} \) (or \( \mathbf{(4.27)} \)) has no magnetic potentials.
Lemma 5 For the Dirac equation (1.17) in 1D and 2D, and for the Dirac equation (1.7) in 1D, 2D and 3D, when there is no magnetic potential, i.e., when \( A_1(x) = A_2(x) = A_3(x) \equiv 0 \), we have

\[ [W, [T, W]] = 0. \] (3.19)

4 A fourth-order compact time-splitting Fourier pseudospectral method

In this section, we present a fourth-order compact time-splitting Fourier pseudospectral method for the Dirac equation (1.7) (or (1.17)) by using the \( S_{4c} \) method (2.14) for time integration followed by the Fourier pseudospectral method for spatial discretization.

4.1 Time integration by the \( S_{4c} \) method in 1D

For simplicity of notations, we present the numerical method for (1.17) in 1D first. Similar to most works in the literatures for the analysis and computation of the Dirac equation (cf. [8, 10, 13] and references therein), in practical computation, we truncate the whole space problem onto an interval \( \Omega = (a, b) \) with periodic boundary conditions. The truncated interval is large enough such that the truncation error is negligible. In 1D, the Dirac equation (1.17) with periodic boundary conditions collapses to

\[
\begin{align*}
&i\delta \partial_t \Phi = \left(-\frac{\delta}{\epsilon} \sigma_1 \partial_x + \frac{V(x)}{\epsilon^2} \sigma_3\right) \Phi + \left(V(x)I_2 - A_1(x) \sigma_1\right) \Phi, \quad x \in \Omega, \quad t > 0, \\
&\Phi(t, a) = \Phi(t, b), \quad \partial_x \Phi(t, a) = \partial_x \Phi(t, b), \quad t \geq 0; \\
&\Phi(0, x) = \Phi_0(x), \quad a \leq x \leq b,
\end{align*}
\] (4.1)

where \( \Phi := \Phi(t, x), \Phi_0(a) = \Phi_0(b) \) and \( \Phi_0(a) = \Phi_0(b) \).

Choose a time step \( \tau > 0 \), denote \( t_n = n\tau \) for \( n \geq 0 \) and let \( \Phi^n(x) \) be an approximation of \( \Phi(t_n, x) \). Re-writing the Dirac equation (4.1) as

\[
\partial_t \Phi = \left(-\frac{1}{\epsilon} \sigma_1 \partial_x - \frac{iV}{\epsilon^2} \sigma_3\right) \Phi - \frac{i}{\delta} \left(V(x)I_2 - A_1(x) \sigma_1\right) \Phi := (T + W) \Phi,
\] (4.2)

then we can apply the \( S_{4c} \) method (2.14) for time integration over the time interval \([t_n, t_{n+1}]\) as

\[
\Phi^{n+1}(x) = S_{4c}(\tau) \Phi^n(x) := e^{\frac{\tau}{\delta} W} e^{\frac{i}{\epsilon} \frac{\tau}{2} T} e^{\frac{i}{\epsilon^2} \frac{\tau^2}{8} W} e^{\frac{i}{\epsilon} \frac{\tau}{2} T} e^{\frac{\tau}{\delta} W} \Phi^n(x), \quad a \leq x \leq b, \quad n \geq 0,
\] (4.3)

where the two operators \( T \) and \( W \) are given in (3.4) and the operator \( \hat{W} \) is given in (3.9). In order to calculate \( e^{\frac{\tau}{\delta} T} \), we can discretize it in space via Fourier spectral method and then integrate (in phase space or Fourier space) in time exactly \( [9,13] \). Since \( W \) is diagonalizable
where $\Lambda_2(x) = \text{diag}(\lambda_+^{(2)}(x), \lambda_-^{(2)}(x))$ with $\lambda^{(2)}_\pm(x) = \frac{\nu(x) \pm A_1(x)}{\sqrt{144\delta^4\varepsilon^4 + \nu^2\tau^4A_1^2(x)}}$ and

$$
P_\pm(x) = \frac{1}{\sqrt{2\beta}(x)} \begin{pmatrix} \sqrt{\beta_1(x) + \beta_2(x)} & \sqrt{\beta_1(x) - \beta_2(x)} \\ -\sqrt{\beta_1(x) - \beta_2(x)} & \sqrt{\beta_1(x) + \beta_2(x)} \end{pmatrix}, \quad a \leq x \leq b, \quad (4.5)
$$

with $\beta_1(x) = \sqrt{144\delta^4\varepsilon^4 + \nu^2\tau^4A_1^2(x)}, \quad \beta_2(x) = \nu^2\tau^2A_1(x), \quad a \leq x \leq b. \quad (4.6)$

Thus we have

$$
e^{\frac{2\pi}{\lambda}i\tau P_2(x)A_2(x)\tau P_2(x)^*} = P_\pm(x)e^{\frac{2\pi}{\lambda}i\tau A_\pm(x)\tau P_\pm(x)^*}, \quad a \leq x \leq b. \quad (4.7)
$$

4.2 Full discretization in 1D

Choose a mesh size $h := \Delta x = \frac{b-a}{M}$ with $M$ being an even positive integer and denote the grid points as $x_j := a + jh$, for $j = 0, 1, \ldots, M$. Denote $X_M = \{ U = (U_0, U_1, \ldots, U_M)^T \ | \ U_j \in \mathbb{C}^2, j = 0, 1, \ldots, M, \ U_0 = U_M \}$. For any $U \in X_M$, we denote its Fourier representation as

$$
U_j = \sum_{l=-M/2}^{M/2-1} \tilde{U}_l e^{i\mu_l(j-a)} = \sum_{l=-M/2}^{M/2-1} \tilde{U}_l e^{2\pi i l \mu/M}, \quad j = 0, 1, \ldots, M, \quad (4.8)
$$

where $\mu_l$ and $\tilde{U}_l \in \mathbb{C}^2$ are defined as

$$
\mu_l = \frac{2\pi}{b-a}, \quad \tilde{U}_l = \frac{1}{M} \sum_{j=0}^{M-1} U_j e^{-2\pi i l \mu/M}, \quad l = -\frac{M}{2}, \ldots, \frac{M}{2} - 1. \quad (4.9)
$$

For $U \in X_M$ and $u(x) \in L^2(\Omega)$, their $l^2$-norms are defined as

$$
||U||^2_{l^2} := h \sum_{j=0}^{M-1} |U_j|^2, \quad ||u||^2_{l^2} := h \sum_{j=0}^{M-1} |u(x_j)|^2. \quad (4.10)
$$

Let $\Phi^j_{\tau}$ be the numerical approximation of $\Phi(t_n, x_j)$ and denote $\Phi^n = (\Phi^0_{\tau}, \Phi^1_{\tau}, \ldots, \Phi^n_{\tau})^T \in X_M$ as the solution vector at $t = t_n$. Take $\Phi^0_{\tau} = \Phi_0(x_j)$ for $j = 0, \ldots, M$, then a fourth-order compact time-splitting Fourier pseudospectral $(S_{4c})$ discretization for the Dirac equation
The $S_{4c}$ method (4.11) is explicit, its memory cost is $O(M)$ and its computational cost per time step is $O(M \ln M)$, it is fourth-order accurate in time and spectral accurate in space. In addition, it conserves the total probability in the discretized level, as shown in the following lemma.

**Lemma 6** For any $\tau > 0$, the $S_{4c}$ method (4.11) conserves the mass in the discretized level, i.e.

$$\left\| \Phi_j^{n+1} \right\|_2^2 := h \sum_{j=0}^{M-1} \left| \Phi_j^{n+1} \right|^2 = h \sum_{j=0}^{M-1} \left| \Phi_j^n \right|^2 = h \sum_{j=0}^{M-1} \left| \Phi_0(x_j) \right|^2 = \left\| \Phi_0 \right\|_2^2, \quad n \geq 0. \tag{4.14}$$
Proof Noticing $W(x_j)^* = -W(x_j)$ and thus $(e^{\frac{\pi}{2} i e W(x_j)})^* e^{\frac{\pi}{2} i e W(x_j)} = I_2$, from (4.11) and summing for $j = 0, 1, \ldots, M - 1$, we get

$$\left\| \Phi^{n+1} \right\|_\rho^2 = h \sum_{j=0}^{M-1} \left\| \Phi^{(n+1)}_j \right\|_\rho^2 = h \sum_{j=0}^{M-1} \left\| e^{\frac{\pi}{2} i t e W(x_j)} \Phi^{(4)}_j \right\|_\rho^2 = h \sum_{j=0}^{M-1} \left\| \left( e^{\frac{\pi}{2} i t e W(x_j)} \right)^* e^{\frac{\pi}{2} i t e W(x_j)} \Phi^{(4)}_j \right\|_\rho^2$$

Similarly, we have

$$\left\| \Phi^{n+1} \right\|_\rho^2 = h \sum_{j=0}^{M-1} \left\| \Phi^{(n+1)}_j \right\|_\rho^2 = h \sum_{j=0}^{M-1} \left\| \Phi^{(4)}_j \right\|_\rho^2, \quad n \geq 0. \quad (4.15)$$

Similarly, using the Parseval’s identity and noticing $I_2^* = -I_2$ and thus $(e^{\frac{\pi}{2} i t e W(x_j)})^* e^{\frac{\pi}{2} i t e W(x_j)} = I_2$, we get

$$\left\| \Phi^{(4)}_j \right\|_\rho^2 = \left\| \Phi^{(3)}_j \right\|_\rho^2, \quad \left\| \Phi^{(2)}_j \right\|_\rho^2 = \left\| \Phi^{(1)}_j \right\|_\rho^2.$$  \quad (4.16)

Combining (4.15), (4.16) and (4.17), we obtain

$$\left\| \Phi^{n+1} \right\|_\rho^2 = \left\| \Phi^{(4)}_j \right\|_\rho^2 = \left\| \Phi^{(3)}_j \right\|_\rho^2, \quad \left\| \Phi^{(2)}_j \right\|_\rho^2 = \left\| \Phi^{(1)}_j \right\|_\rho^2, \quad \left\| \Phi^n_0 \right\|_\rho^2, \quad n \geq 0. \quad (4.17)$$

Using the mathematical induction, we get the mass conservation (4.14).

4.4 Discussion on extension to 2D and 3D

When there is no magnetic potential, i.e., when $A_1(x) = A_2(x) = A_3(x) \equiv 0$ in the Dirac equation (1.7) in 2D and (1.7) in 2D and 3D, from Lemma 5 we know that the double commutator $[W, [T, W]] = 0$. In this case, noting (2.15), we have

$$\tilde{W} = W + \frac{1}{48} \tau^2 [W, [T, W]] = W. \quad (4.19)$$

Then the $S_{4c}$ method (2.14) collapses to

$$u(t, x) \approx S_{4c}(\tau) u_0(x) := e^{\frac{\pi}{2} i t e W} e^{\frac{\pi}{2} i T e W} e^{\frac{\pi}{2} i t e W} u_0(x). \quad (4.20)$$

Applying the $S_{4c}$ method (4.20) to integrate the Dirac equation (1.7) in 2D over the time interval $[t_n, t_{n+1}]$ with $\Phi(t_n, x) = \Phi^n(x)$ given, we obtain

$$\Phi^{n+1}(x) = S_{4c}(\tau) \Phi^n(x) = e^{\frac{\pi}{2} i t e W} e^{\frac{\pi}{2} i T e W} e^{\frac{\pi}{2} i t e W} \Phi^n(x), \quad x \in \Omega, \quad n \geq 0, \quad (4.21)$$

where $T$ and $W$ are given in (3.12). Similarly, applying the $S_{4c}$ method (4.20) to integrate the Dirac equation (1.7) in 2D and 3D over the time interval $[t_n, t_{n+1}]$ with $\Psi(t_n, x) = \Psi^n(x)$
given, we obtain
\[
Ψ_{n+1}(x) = S_{4c}(τ)Ψ^n(x) = e^{\frac{1}{4}τW}e^{\frac{1}{2}τT}e^{\frac{1}{4}τW}e^{\frac{1}{2}τT}Ψ^n(x), \quad x ∈ Ω, \quad n ≥ 0, \quad (4.22)
\]
where \( T \) and \( W \) are given in (3.14) and (3.17) for 2D and 3D, respectively. In practical computation, the operators \( e^{\frac{1}{4}τW} \) and \( e^{\frac{1}{2}τT} \) in (4.21) and (4.22) can be evaluated in physical space directly and easily [9]. For the operator \( e^{\frac{1}{2}τT} \), it can be discretized in space via Fourier spectral method and then integrate (in phase space or Fourier space) in time exactly. For details, we refer to [9, 13] and references therein. In fact, the implementation of the \( S_{4c} \) method in this case is much simpler than that of the \( S_4 \) and \( S_{4RK} \) methods.

Of course, when the magnetic potential is nonzero in the Dirac equation (1.17) in 2D and (1.7) in 2D and 3D, one has to adapt the formulation (4.20) for \( S_{4c} \) method. In this case, the main difficulty is how to efficiently and accurately evaluate the operator \( e^{\frac{1}{2}τW} \). This can be done by using the method of characteristics and the nonuniform fast Fourier transform (NUFFT), which has been developed for the magnetic Schrödinger equation. For details, we refer to [19, 44] and references therein. Of course, it is a little more tedious in practical implementation for \( S_{4c} \) method than that for the \( S_4 \) and \( S_{4RK} \) methods in this situation.

5 Comparison of different time-splitting methods

In this section, we compare the fourth-order compact time-splitting Fourier pseudospectral \( S_{4c} \) method (4.11) with other time-splitting methods including the first-order time-splitting (\( S_1 \)) method, the second-order time-splitting (\( S_2 \)) method, the fourth-order time-splitting (\( S_4 \)) method and the fourth-order partitioned Runge-Kutta time-splitting (\( S_{4RK} \)) method in terms of accuracy and efficiency as well as long time behavior.

5.1 An example in 1D

For simplicity, we first consider an example in 1D. In the Dirac equation (1.17), we take \( d = 1, \varepsilon = \delta = \nu = 1 \) and

\[
V(x) = \frac{1 - x}{1 + x^2}, \quad A_1(x) = \frac{(x+1)^2}{1 + x^2}, \quad x ∈ \mathbb{R}. \quad (5.1)
\]

The initial data in (1.18) is taken as:

\[
Φ_1(0,x) = e^{-x^2/2}, \quad Φ_2(0,x) = e^{-(x-1)^2/2}, \quad x ∈ \mathbb{R}. \quad (5.2)
\]

The problem is solved numerically on a bounded domain \( Ω = (-32, 32) \), i.e. \( a = -32 \) and \( b = 32 \).
Due to the fact that the exact solution is not available, we obtain a numerical ‘exact’ solution by using the $S_{1c}$ method with a fine mesh size $h_e = \frac{h_0}{4}$ and a small time step $\tau_e = 10^{-5}$. Let $\Phi^\alpha$ be the numerical solution obtained by a numerical method with mesh size $h$ and time step $\tau$. Then the error is quantified as

$$e_{\Phi}(t_n) = \|\Phi^\alpha - \Phi(t_n, \cdot)\|_2 = \sqrt{\frac{1}{h} \sum_{j=0}^{M-1} \|\Phi(t_n, x_j) - \Phi^\alpha_j\|^2}. \quad (5.3)$$

In order to compare the spatial errors, we take time step $\tau = \tau_e = 10^{-5}$ such that the temporal discretization error could be negligible. Table 5.1 lists numerical errors $e_{\Phi}(t = 6)$ for different time-splitting methods under different mesh size $h$. We remark here that, for the $S_1$ method, in order to observe the spatial error when the mesh size $h = \frac{h_0}{2^3}$, one has to choose time step $\tau \leq 10^{-10}$ which is too small and thus the error is not shown in the table for this case. From Table 5.1 we could see that all the numerical methods are spectral order accurate in space (cf. each row in Table 5.1).

In order to compare the temporal errors, we take mesh size $h = h_e = \frac{1}{40}$ such that the spatial discretization error could be negligible. Table 5.2 lists numerical errors $e_{\Phi}(t = 6)$ for different time-splitting methods under different time step $\tau$. In the table, we use second (s) as the unit for CPU time. For comparison, Figure 5.1 plots $e_{\Phi}(t = 6)$ and $e_{\Phi}(t = 6)/\tau^\alpha$ with $\alpha$ taken as the order of accuracy of a certain numerical method (in order to show the constants $C_1$ in (2.6), $C_2$ in (2.8), $C_4$ in (2.11), $C_4$ in (2.13) and $\tilde{C}_4$ in (2.16)) for different time-splitting methods under different time step $\tau$.

From Table 5.2 and Figure 5.1 we can draw the following conclusions: (i) The $S_1$ method is first-order in time, the $S_2$ method is second-order in time, and the $S_4$, $S_{4c}$ and $S_{4RK}$ methods are all fourth-order in time (cf. Table 5.2 and Figure 5.1 left). (ii) For any fixed mesh $h$ and time $\tau$, the computational time for $S_1$ and $S_2$ are quite similar, the computational time of $S_{4c}$, $S_4$ and $S_{4RK}$ are about two times, three times and six times of the $S_2$ method, respectively (cf. Table 5.2). (iii) Among the three fourth-order time-splitting methods, $S_{4c}$ and $S_{4RK}$ are quite similar in terms of numerical errors for any fixed $\tau$ and they are much smaller than that of the $S_4$ method, especially when the $\tau$ is not so small (cf. Table

| $h_0$ | $h_0/2$ | $h_0/2^2$ | $h_0/2^3$ |
|------|---------|-----------|-----------|
| $S_1$ | 1.01    | 5.16E-2   | 7.07E-5   | $-$       |
| $S_2$ | 1.01    | 5.16E-2   | 6.96E-5   | 1.92E-10  |
| $S_4$ | 1.01    | 5.16E-2   | 6.96E-5   | 3.52E-10  |
| $S_{4c}$ | 1.01 | 5.16E-2   | 6.96E-5   | 3.06E-10  |
| $S_{4RK}$ | 1.01 | 5.16E-2   | 6.96E-5   | 5.15E-10  |

Table 5.1 Spatial errors $e_{\Phi}(t = 6)$ of different time-splitting methods under different mesh size $h$ for the Dirac equation (1.17) in 1D.
Table 5.2 Temporal errors $e_{\Phi}(t = 6)$ of different time-splitting methods under different time step $\tau$ for the Dirac equation (1.17) in 1D. Here we also list convergence rates and computational time (CPU time in seconds) for comparison.

![Table and Figure](left) and Figure 5.1 (right). (iv) For the constants in front of the convergence rates of different methods, $C_4 \gg C_1 \sim C_2 \gg \tilde{C}_4 \sim \tilde{C}_2$ (cf. Figure 5.1 right). (v) For the $S_4$ method, it suffers
from convergence rate reduction when the time step is not small and a very large constant in front of the convergence rate. Thus this method is, in general, to be avoided in practical computation, which has been observed when it is applied for the nonlinear Schrödinger equation too [59].

To compare the long time behavior of different time-splitting methods, Figure 5.2 depicts $e_{\Phi}(t)$ under mesh size $h = \frac{1}{16}$ and time step $\tau = 0.1$ for $0 \leq t \leq T := 50$.

From Figure 5.2 we can observe: (i) The errors increase very fast when $t$ is small, e.g. $0 \leq t \leq O(1)$, and they almost don’t change when $t \gg 1$, thus they are suitable for long time simulation, especially the fourth-order methods. (ii) When $t$ is not large, the error of the $S_4$ method is about 10 times bigger than that of the $S_{4c}$ method; however, when $t \gg 1$, it becomes about 100 times larger. (iii) The error of the $S_{4RK}$ method is always the smallest among all the time-splitting methods.

Based on the efficiency and accuracy as well as long time behavior, in conclusion, for the three fourth-order time-splitting methods, $S_{4c}$ is more accurate than $S_4$ and it is more efficient than $S_{4RK}$. Thus the $S_{4c}$ method is highly recommended for studying the dynamics of the Dirac equation, especially in 1D.

5.2 An example in 2D

For simplicity, here we only compare the three fourth-order integrators, i.e., $S_{4c}$, $S_4$ and $S_{4RK}$ via an example in 2D. In order to do so, in the Dirac equation (1.17), we take $d = 2,$
A fourth-order compact time-splitting Fourier pseudospectral method for the Dirac equation

\[ h_0 = \frac{1}{2}, \quad h_0/2, \quad h_0/2^3 \]

\[
\begin{array}{|c|c|c|c|}
\hline
\text{Method} & h_0/2 & h_0/2^3 & h_0/2^3 \\
\hline
S_4 & 1.10 & 1.01E-1 & 3.83E-4 & 7.33E-10 \\
S_{4c} & 1.10 & 1.01E-1 & 3.83E-4 & 7.33E-10 \\
S_{4RK} & 1.10 & 1.01E-1 & 3.83E-4 & 7.34E-10 \\
\hline
\end{array}
\]

Table 5.3: Spatial errors \( e_\Phi(t = 2) \) of different time-splitting methods under different mesh size \( h \) for the Dirac equation (1.17) in 2D.

\[ \varepsilon = \delta = \nu = 1 \]

and take the potential in honey-comb form

\[
V(\mathbf{x}) = \cos \left( \frac{4\pi}{\sqrt{3}} \mathbf{e}_1 \cdot \mathbf{x} \right) + \cos \left( \frac{4\pi}{\sqrt{3}} \mathbf{e}_2 \cdot \mathbf{x} \right) + \cos \left( \frac{4\pi}{\sqrt{3}} \mathbf{e}_3 \cdot \mathbf{x} \right),
\]

with

\[
A_1(x) = A_2(x) = 0, \quad x \in \mathbb{R}^2,
\]

(5.4)

(5.5)

The initial data in (1.18) is taken as:

\[
\phi_1(0, \mathbf{x}) = e^{-\frac{x_1^2 + x_2^2}{2}}, \quad \phi_2(0, \mathbf{x}) = e^{-\frac{(x_1 - 1)^2 + x_2^2}{2}}, \quad \mathbf{x} = (x, y)^T \in \mathbb{R}^2.
\]

(5.6)

The problem is solved numerically on a bounded domain \( \Omega = (-10, 10) \times (-10, 10) \).

Similar to the 1D case, we obtain a numerical ‘exact’ solution by using the \( S_{4c} \) method with a fine mesh size \( h_e = \frac{1}{32} \) and a small time step \( \tau_e = 10^{-4} \). The error for the numerical solution \( \Phi^n \) with mesh size \( h \) and time step \( \tau \) is quantified as

\[
e_\Phi(t_n) = \| \Phi^n - \Phi(t_n, \cdot) \|_2 = h \sqrt{\sum_{j=0}^{M-1} \sum_{l=0}^{M-1} |\Phi(t_n, x_j, y_l) - \Phi^n_{jl}|^2}.
\]

(5.7)

Similar to the 1D case, in order to compare the spatial errors, we take time step \( \tau = \tau_e = 10^{-4} \) such that the temporal discretization error could be negligible. Table 5.3 lists numerical errors \( e_\Phi(t = 2) \) for different time-splitting methods under different mesh size \( h \). In order to compare the temporal errors, we take mesh size \( h = h_e = \frac{1}{32} \) such that the spatial discretization error could be negligible. Table 5.4 lists numerical errors \( e_\Phi(t = 2) \) for different time-splitting methods under different time step \( \tau \).

From Tables 5.3 & 5.4, we can draw the following conclusions: (i) All the three methods are spectrally accurate in space and fourth-order in time. (ii) For any fixed mesh size \( h \) and time step \( \tau \), the computational times of the \( S_4 \) and \( S_{4RK} \) methods are approximately 1.5 times and 3 times more than that of the \( S_{4c} \) method, respectively. (iii) \( S_{4c} \) and \( S_{4RK} \) are quite similar in terms of numerical errors for any fixed \( \tau \) and the errors are much smaller than that of the \( S_4 \) method, especially when \( \tau \) is not so small. (iv) Again, order reduction in time was
Table 5.4 Temporal errors $e_\Phi(t=2)$ of different fourth order time-splitting methods under different time step $\tau$ for the Dirac equation (1.17) in 2D. Here we also list convergence rates and computational time (CPU time in seconds) for comparison.

| Method | $\tau_0$ = 1/2 | $\tau_0/2$ | $\tau_0/2^2$ | $\tau_0/2^3$ | $\tau_0/2^4$ | $\tau_0/2^5$ | $\tau_0/2^6$ |
|--------|----------------|-----------|-------------|-------------|-------------|-------------|-------------|
| $S_4$  | Error          | 4.33E-1   | 2.57E-2     | 3.53E-3     | 2.83E-4     | 1.88E-5     | 1.20E-6     | 7.51E-8     |
| Order  | –              | 4.07      | 2.87        | 3.64        | 3.91        | 3.98        | 3.99        |
| CPU Time | 0.20         | 0.26      | 0.45        | 1.04        | 1.63        | 3.37        | 6.54        |
| $S_{4c}$ | Error        | 6.75E-2   | 3.18E-3     | 7.91E-5     | 4.70E-6     | 2.91E-7     | 1.81E-8     | 1.13E-9     |

observed in the $S_4$ method when $\tau$ is not small, however, there is almost no order reduction in time for the $S_{4c}$ and $S_{4RK}$ methods.

Again, based on the efficiency and accuracy for the Dirac equation in high dimensions, in conclusion, for the three fourth-order time-splitting methods, $S_{4c}$ is more accurate than $S_4$ and it is more efficient than $S_{4RK}$. Thus the $S_{4c}$ method is highly recommended for studying the dynamics of the Dirac equation in high dimensions, especially without magnetic potential.

6 Spatial/temporal resolution of the $S_{4c}$ method in different parameter regimes

In this section, we study numerically temporal/spatial resolution of the fourth-order compact time-splitting Fourier pseudospectral $S_{4c}$ method (4.11) for the Dirac equation in different parameter regimes. We take $d = 1$ and the electromagnetic potentials as (5.1) in Dirac equation (1.17). To quantify the numerical error, we adapt the relative errors of the wave function $\Phi$, the total probability density $\rho$ and the current $J$ as

$$e_\Phi(t_n) = \frac{||\Phi^n - \Phi(t_n, \cdot)||_2}{||\Phi(t_n, \cdot)||_2}, \quad e_\rho(t_n) = \frac{||\rho^n - \rho(t_n, \cdot)||_2}{||\rho(t_n, \cdot)||_2}, \quad e_J(t_n) = \frac{||J^n - J(t_n, \cdot)||_2}{||J(t_n, \cdot)||_2},$$

(6.1)

where $\rho^n$ and $J^n$ are obtained from the wave function $\Phi^n$ via (1.21) and (1.23) with $d = 1$, respectively. Again, the numerical ‘exact’ solution is obtained by using the $S_{4c}$ method with a very fine mesh $h = h_e$ and a very small time step $\tau = \tau_e$. 
6.1 In the nonrelativistic limit regime

Here we take $\delta = \nu = 1$, $\varepsilon \in (0, 1]$ and the initial data in (1.18) is taken as (5.2). In this parameter regime, the solution propagates waves with wavelength at $O(1)$ and $O(\varepsilon^2)$ in space and time, respectively. The problem is solved numerically on a bounded domain $\Omega = (-32, 32)$, i.e. $a = -32$ and $b = 32$. Similar to the second-order time-splitting Fourier pseudospectral method [9], the $S_{4c}$ method converges uniformly with respect to $\varepsilon \in (0, 1]$ at spectral order in space. Detailed numerical results are omitted here for brevity. Here we only present temporal errors by taking $h = h_e = \frac{1}{16}$ so that the spatial discretization error could be negligible. Table 6.1 shows the temporal errors $\varepsilon^r(\Phi(t = 6))$ for the wave function under different $\tau$ and $\varepsilon \in (0, 1]$. Similarly, Tables 6.2 and 6.3 depict the temporal errors $\varepsilon^r(\rho(t = 6))$ and $\varepsilon^r(J(t = 6))$ for the probability and current, respectively.

From Tables 6.1-6.3 when $\tau \leq \varepsilon^2$, fourth-order convergence is observed for the $S_{4c}$ method in the relative error for the wave function, probability and current. This suggests that the $\varepsilon$-scalability for the $S_{4c}$ method in the nonrelativistic limit regime is: $h = O(1)$ and $\tau = O(\varepsilon^2)$. In addition, noticing $\Phi = O(1)$, $\rho = O(1)$ and $J = O(\varepsilon^{-1})$ when $0 \leq \varepsilon \ll 1$, we can formally observe the following error bounds for $0 < \varepsilon \leq 1$, $\tau \leq \varepsilon^2$ and $0 \leq n \leq \frac{\varepsilon}{\tau}$

$$
\|\Phi^n - \Phi(t_n, \cdot)\|_{L^2} \lesssim h^{m_0} + \frac{\tau^4}{\varepsilon^6}, \quad \|\rho^n - \rho(t_n, \cdot)\|_{L^2} \lesssim h^{m_0} + \frac{\tau^4}{\varepsilon^6},
$$

$$
\|J^n - J(t_n, \cdot)\|_{L^2} \lesssim \frac{1}{\varepsilon} \left( h^{m_0} + \frac{\tau^4}{\varepsilon^6} \right).
$$

(6.2)

where $m_0 \geq 2$ depends on the regularity of the solution. Rigorous mathematical justification is still on-going.
6.2 In the semiclassical limit regime

Here we take $\varepsilon = \nu = 1, \delta \in (0, 1]$. The initial data in (1.18) is taken as
\[
\phi_1(0,x) = \frac{1}{2} e^{-4x^2} e^{S_0(x)/\delta} \left(1 + \sqrt{1 + S_0'(x)^2}\right),
\]
and
\[
\phi_2(0,x) = \frac{1}{2} e^{-4x^2} e^{S_0(x)/\delta} S_0(x), \quad x \in \mathbb{R},
\]
with
\[
S_0(x) = \frac{1}{40} (1 + \cos(2\pi x)), \quad x \in \mathbb{R}.
\]
Tables 6.4 and 6.5 depict the spatial errors \( \epsilon_\delta \) from Tables 6.7-6.9, when \( h = \frac{1}{16} \) and \( \delta \in [0, 1] \) with \( \tau = \tau_0 = 10^{-4} \), such that the temporal discretization error could be negligible. Similarly, Table 6.7 shows the temporal errors \( \epsilon_t \) for the wave function under different \( \tau \) and \( \delta \in (0, 1] \) with \( h = \frac{1}{16} \) so that the spatial discretization error could be negligible. From Tables 6.4-6.5, when \( h \lesssim \delta \), spatial convergence (in space) is observed for the \( S_{ac} \) method in the relative error for the wave function. Similarly, from Tables 6.7-6.8, when \( \tau \lesssim \delta \), fourth-order convergence (in time) is observed for the \( S_{ac} \) method in the relative error for the wave function. These suggest that the \( \delta \)-scalability for the \( S_{ac} \) method in the semiclassical limit regime is: \( h = O(\delta) \) and \( \tau = O(\delta) \). In addition, noticing \( \Phi = O(1), \rho = O(1) \), and \( J = O(1) \) when \( 0 \leq \delta \ll 1 \), we can

\end{equation}

where $m_0 \geq 2$ depends on the regularity of the solution. Rigorous mathematical justification is still on-going.

6.3 In the simultaneously nonrelativistic and massless limit regime

We take $d = 1$, $\delta = 1$ and $\nu = \epsilon$ in (1.17) with $\epsilon \in (0, 1]$. The initial data in (1.18) is taken as $\delta_0$. In this parameter regime, the solution propagates waves with wavelength at $O(1)$ and $O(\epsilon)$ in space and time, respectively. The problem is solved numerically on
a bounded domain $\Omega = (-128, 128)$, i.e. $a = -128$ and $b = 128$ by $S_{\text{hc}}$. Similar to the nonrelativistic limit regime, the $S_{\text{hc}}$ method converges uniformly with respect to $\varepsilon \in (0, 1]$ at spectral order in space. Detailed numerical results are omitted here for brevity. Here we only present temporal errors by taking $h = h_c = \frac{1}{10}$ so that the spatial discretization error could be negligible. Table 6.10 shows the temporal errors $e_{\Phi}^\tau (t = 2)$ for the wave function under different $\tau$ and $\varepsilon \in (0, 1]$. Similarly, Tables 6.11 and 6.12 depict the temporal errors $e_{\rho}^\tau (t = 2)$ and $e_{J}^\tau (t = 2)$ for the probability and current, respectively.

Table 6.10 Temporal errors $e_\Phi(t = 2)$ of $S_{4c}$ under different $\tau$ and $\epsilon$ for the Dirac equation (1.17) in 1D in the simultaneously nonrelativistic and massless limit regime.

From Tables 6.10 and 6.12 when $\tau \lesssim \epsilon$, fourth-order convergence is observed for the $S_{4c}$ method in the relative error for the wave function, probability and current. This suggests that the $\epsilon$-scalability for the $S_{4c}$ method in the simultaneously nonrelativistic and massless limit regime is: $h = O(1)$ and $\tau = O(\epsilon)$. In addition, noticing $\Phi = O(1), \rho = O(1)$ and $J = O(\epsilon^{-1})$.
when $0 \leq \varepsilon \ll 1$, we can formally observe the following error bounds for $0 < \varepsilon \leq 1$, $\tau \lesssim \varepsilon$ and $0 \leq n \leq \frac{T}{\tau}$

$$
\| \Phi^n - \Phi(t_n, \cdot) \|_{L^2} \lesssim h^{m_0} + \frac{\tau^4}{\varepsilon^3}, \quad \| \rho^n - \rho(t_n, \cdot) \|_{L^2} \lesssim h^{m_0} + \frac{\tau^4}{\varepsilon^3},$$

$$
\| J^n - J(t_n, \cdot) \|_{L^2} \lesssim \frac{1}{\varepsilon} \left( h^{m_0} + \frac{\tau^4}{\varepsilon^3} \right). \tag{6.6}
$$

where $m_0 \geq 2$ depends on the regularity of the solution. Rigorous mathematical justification is still on-going.

Based on the discussion in Section 1 and numerical comparison results in this section, Table 6.13 lists spatial/temporal wavelengths of the Dirac equation under different parameter regimes and the corresponding spatial/temporal resolution of the $S_{4c}$ method.

### 7 Conclusion

A new fourth-order compact time-splitting Fourier pseudospectral ($S_{4c}$) method was proposed for the Dirac equation. It is explicit, fourth-order in time and spectral accurate in space. One major advantage in the method is to avoid using negative time steps in integrating sub-problems via the double commutator. Numerical results showed that it is much more accurate than first-order and second-order time-splitting methods, and it is more accurate

| $\varepsilon_0 = 1$ | $\varepsilon_0 / 2$ | $\varepsilon_0 / 2^2$ | $\varepsilon_0 / 2^3$ | $\varepsilon_0 / 2^4$ | $\varepsilon_0 / 2^5$ | $\varepsilon_0 / 2^6$ |

Table 6.13: Spatial/temporal wavelengths of the Dirac equation under different parameter regimes and the corresponding spatial/temporal resolution of the $S_{4c}$ method.

than the standard fourth-order time-splitting method and is more efficient than the partitioned Runge-Kutta time-splitting method, especially in 1D or in high dimensions without magnetic potentials. In addition, it is very robust for simulating long time dynamics. Spatial and temporal resolution of the proposed numerical method was studied numerically for the Dirac equation under different parameter regimes including the nonrelativistic limit regime, the semiclassical limit regime, and the simultaneously nonrelativistic and massless limit regime. Based on our extensive numerical results, for numerical simulation of the dynamics of the Dirac equation in 1D or in high dimensions without magnetic potential, the $S_{4c}$ method is a very efficient and accurate as well as simple numerical method. Of course, for the Dirac equation in high dimensions with magnetic potential, $S_{4RK}$ is a good choice.

Proof Combining (3.12) and (3.2), we obtain

\[
[W, [T, W]] = -\frac{1}{\varepsilon} [W, [\sigma_1 \partial_1, W]] - \frac{1}{\varepsilon} [W, [\sigma_2 \partial_2, W]] - \frac{iV}{\delta \varepsilon^2} [W, [\sigma_3, W]].
\] (A.1)

From (A.3), we have

\[
\sigma_j^2 = I_2, \quad \sigma_j \sigma_l = -\sigma_l \sigma_j, \quad 1 \leq j \neq l \leq 3,
\]

\[
\sigma_1 \sigma_2 = i \sigma_3, \quad \sigma_2 \sigma_3 = i \sigma_1, \quad \sigma_3 \sigma_1 = i \sigma_2.
\] (A.2)

Noticing (3.12), (3.1) and (A.2), we get

\[
[W, [\sigma_l \partial_l, W]]
= -\frac{2}{\delta^2} \left( V(\mathbf{x}) I_2 - A_1(\mathbf{x}) \sigma_l - A_2(\mathbf{x}) \sigma_2 \right) \left( \sigma_l \partial_l \right) \left( V(\mathbf{x}) I_2 - A_1(\mathbf{x}) \sigma_l - A_2(\mathbf{x}) \sigma_2 \right) - \frac{1}{\delta^2} \sigma_l \partial_l \partial_1 V(\mathbf{x}) I_2 - \partial_1 A_1(\mathbf{x}) \sigma_l - \partial_1 A_2(\mathbf{x}) \sigma_2

From (1.2) and (3.16), we have
\[
[W, [\sigma_3, W]] = -\frac{1}{\delta^2} \left( 2(V(x)I_2 - A_1(x)\sigma_1 - A_2(x)\sigma_2) \sigma_3(V(x)I_2 - A_1(x)\sigma_1 - A_2(x)\sigma_2) \\
- (V(x)I_2 - A_1(x)\sigma_1 - A_2(x)\sigma_2) \sigma_3(V(x)I_2 - A_1(x)\sigma_1 - A_2(x)\sigma_2)^2 \right)
\]
\[
= \frac{2}{\delta^2} \sigma_3(V(x)I_2 + A_1(x)\sigma_1 + A_2(x)\sigma_2)(A_1(x)\sigma_1 + A_2(x)\sigma_2) \\
- \frac{2}{\delta^2} \sigma_3(A_1(x)\sigma_1 + A_2(x)\sigma_2)(V(x)I_2 - A_1(x)\sigma_1 - A_2(x)\sigma_2) \\
= \frac{4}{\delta^2}(A_1^2(x) + A_2^2(x))\sigma_3.
\]
(A.4)

\[
[W, [\sigma_2\partial_2, W]] = -\frac{4}{\delta^2} (A_1(x)A_2(x)\sigma_1 - A_1^2(x)\sigma_2)\partial_2 - \frac{4}{\delta^2} A_1(x)(\partial_2 A_2(x)\sigma_1 - \partial_2 A_1(x)\sigma_2) \\
+ \frac{4i}{\delta^2} A_1(x)\partial_2 V(x)\sigma_3.
\]
(A.5)

Plugging (A.3), (A.5) and (A.4) into (A.1), after some computation, we can get (3.13).

**Appendix B.** Proof of Lemma 3.4 on double commutator of the Dirac equation in 3D

**Proof** Combining (3.17) and (3.2), we obtain
\[
[W, [T, W]] = -\frac{1}{\delta^2} [W, [\sigma_1 \partial_1, W]] - \frac{1}{\delta^2} [W, [\sigma_2 \partial_2, W]] - \frac{1}{\delta^2} [W, [\sigma_3 \partial_3, W]] - \frac{iV}{\delta^2} [W, [\beta, W]].
\]
(B.1)

From (1.2) and (3.16), we have
\[
\beta^2 = I_4, \quad \alpha_3^2 = I_4, \quad \alpha_j \alpha_l = -\alpha_l \alpha_j, \\
\beta \alpha_j = -\alpha_j \beta, \quad \gamma \alpha_j = \alpha_j \gamma, \quad 1 \leq j \neq l \leq 3,
\]
\[
\alpha_j \alpha_k = i\gamma \alpha_k, \quad \alpha_k \alpha_3 = i\gamma \alpha_3, \quad \alpha_3 \alpha_l = i\gamma \alpha_l.
\]
(B.2)

Noticing (3.17), (3.1) and (B.2), we get
\[
[W, [\beta, W]] = -\frac{1}{\delta^2} \left( 2(V(x)I_4 - \sum_{j=1}^3 A_j(x)\alpha_j) \beta \left( V(x)I_4 - \sum_{j=1}^3 A_j(x)\alpha_j \right) \\
- (V(x)I_4 - \sum_{j=1}^3 A_j(x)\alpha_j)^2 \beta \left( V(x)I_4 - \sum_{j=1}^3 A_j(x)\alpha_j \right)^2 \right)
\]
\[
= -\frac{2}{\delta^2} \beta \left( V(x)I_4 + \sum_{j=1}^3 A_j(x)\alpha_j \right) \left( V(x)I_4 - \sum_{j=1}^3 A_j(x)\alpha_j \right) \\
+ \frac{1}{\delta^2} \beta \left( V(x)I_4 + \sum_{j=1}^3 A_j(x)\alpha_j \right)^2 \beta \left( V(x)I_4 - \sum_{j=1}^3 A_j(x)\alpha_j \right)^2 \\
= \frac{4}{\delta^2}(A_1^2(x) + A_2^2(x) + A_3^2(x))\beta.
\]
(B.3)
Plugging (B.4), (B.5), (B.6) and (B.3) into (B.1), after some computation, we obtain (3.18).
