DOI: 10.3892/etm.2019.7845

Abstract. Pancreatic cancer is a common malignancy that has a poor prognosis and limited therapeutic options. Enhancer of zeste homolog 2 (EZH2) serves a key role in the progression of different types of cancers. The effect of GSK343 (a competitive inhibitor of EZH2) on pancreatic cancer cells was assessed in the present study. Cell viability was evaluated using MTT and cell counting kit-8 assays in AsPC-1 and PANC-1 cells. Flow cytometry and an EdU assay were also performed to assess the effects of GSK343 on cell proliferation, apoptosis and the cell cycle. The induction of autophagy and associated molecular mechanisms were studied using fluorescence microscopy and western blot analysis. The results demonstrated that GSK343 inhibited cell viability in a dose- and time-dependent manner. Furthermore, GSK343 suppressed cell proliferation, promoted apoptosis and blocked cell cycle progression at the G1-phase. Furthermore, GSK343 induced autophagy in pancreatic cancer via the AKT/mTOR signaling pathway. In conclusion, GSK343 exhibited an anti-cancer effect on pancreatic cancer cells, downregulating the AKT/mTOR signaling pathway.

Introduction

Pancreatic cancer is a common malignancy with a poor prognosis. According to predictions by the American Cancer Society, 56,770 new pancreatic carcinoma diagnoses will be made in 2019 and as such, will become the fourth-highest cause of mortality in the US (with rates as high as 80%), irrespective of sex (1). It is also estimated that pancreatic cancer will surpass liver cancer in becoming the second-highest cause of cancer-associated deaths by 2030 (2). Due to the clinically vague nature of early stage disease, the majority of pancreatic cancer diagnoses are only possible after metastasis at more advanced stages (3). Due to pancreatic cancer exhibiting high chemotherapy and radiation therapy resistance, surgical resection is the only effective therapeutic option currently available (3). Novel strategies for treating pancreatic cancer are therefore urgently required.

Enhancer of zeste homolog 2 (EZH2) is the enzymatically active subunit of polycomb repressive complex 2, which catalyzes the trimethylation of lysine 27 on histone 3 (H3K27) by transferring a methyl group from S-adenosyl-L-methionine (SAM), leading to the transcriptional silencing of target genes (4,5). Although the underlying molecular mechanism of EZH2 oncogenic activity is unclear, EZH2 has been revealed to serve a key role in the progression of different types of cancer, including prostate cancer, breast cancer, endometrial cancer, melanoma and hematological malignancies (6-14). A previous study demonstrated that there was a high expression of EZH2 in pancreatic cancer cells and tissues, which was associated with proliferation, invasion and chemoresistance (15). EZH2 overexpression may also be a promising prognostic marker for patients with pancreatic cancer after surgery (16).

GSK343 serves as a SAM-competitive inhibitor, exerting an enzymatically repressive function on EZH2 (17). This is distinct from 3-deazaneplanocin A (DZNep), which inhibits the activity of S-adenosyl-L-homocysteine hydrolase (SAH) (18). Numerous studies have reported an elevated expression of EZH2 in various types of cancer, which is associated with a poor prognosis and metastasis (19-23). The inhibition of EZH2 has been regarded as a novel therapeutic target for various carcinomas (24-28).

The current study aimed to elucidate the effects of GSK343 on pancreatic cancer cells to determine a potential future putative therapeutic strategy. The results of the present study revealed that GSK343 may be a potential anti-cancer drug and may exert an autophagy-inducing effect.
Materials and methods

Materials. GSK343 (cat. no. S7164; Selleck Chemicals) was dissolved in 5 mmol/l DMSO. Primary antibodies against GAPDH (cat. no. 60004-1-lg; Proteintech Group, Inc.), microtubule-associated protein 1 light chain 3 beta (LC3B; cat. no. L7543; Sigma-Aldrich; Merck KGaA), AKT (cat. no. 1085; Abcam), phospho-AKT (cat. no. 2118; Abcam), autophagy-related protein 5 (ATG5; cat. no. 12994; Cell Signaling Technology, Inc.), mTOR (cat. no. 2983; Cell Signaling Technology, Inc.) and phospho-mTOR (cat. no. 5536; Cell Signaling Technology, Inc.). Horseradish peroxidase-conjugated anti-rabbit secondary antibodies (cat. no. A00098; GenScript) or anti-mouse (cat. no. A00160; GenScript) and fluorochrome-conjugated anti-rabbit secondary antibodies (cat. no. E03120; EarthOx Life Sciences) were used at the recommended concentrations outlined by the manufacturer’s protocol.

Cell culture. A primary cancer cell was randomly selected (PANC-1, derived from pancreatic ductal epithelial cells) and a metastatic cancer cell line (AsPC-1, ascites metastasis) was used in the present study to clarify the function of GSK343 (all, American Type Culture Collection). The two pancreatic cell lines were cultured in RPMI 1640 medium (Thermo Fisher Scientific, Inc.) supplemented with 10% FBS (Sigma-Aldrich; Merck KGaA) and incubated at 37°C with 5% CO₂.

MTT assay. AsPC-1 and PANC-1 Cells were plated into 96-well plates (3x10³ cells/well) 24 h (37°C; 5% CO₂) prior to treatment with various concentrations (0, 2.5, 5.0, 7.5, 10.0, 12.5, 15, 17.5, 20 and 25 µmol/l) of GSK343 for an additional 48 h at 37°C with 5% CO₂. A total of 5 mg/ml of MTT (Beijing Solarbio Science & Technology Co., Ltd.) was added into each well for an additional 4 h at 37°C with 5% CO₂. The purple MTT formazan precipitate was dissolved in 200 µl DMSO and the absorption value was measured using a spectrophotometer at 570 nm. Curves were fitted and analyzed with GraphPad software version 6.0 to calculate the IC50 value (GraphPad Software, Inc.).

Cell counting kit-8 (CCK-8) assay. AsPC-1 and PANC-1 cells were seeded at a density of 3x10³ cells per well into 96-well plates 24 h (37°C; 5% CO₂) prior to treatment with the IC50 concentration of GSK343 (12.71 µmol/l for AsPC-1, 12.04 µmol/l for PANC-1) and 20 µmol/l of GSK343 for 48 h, the proportion of AsPC-1 and PANC-1 cells that incorporated EdU, was observed using a fluorescence microscope (Olympus IX71; Olympus Corporation; magnification, x200).

EdU viability assay. A Cell-Light™ EdU Apollo567 In Vitro Imaging kit (Guangzhou RiboBio Co., Ltd.) was used to evaluate the effect of GSK343, according to the manufacturer’s protocol. Following treatment with IC50 concentration of GSK343 (12.71 µmol/l for AsPC-1, 12.04 µmol/l for PANC-1) and 20 µmol/l of GSK343 for 48 h, the proportion of AsPC-1 and PANC-1 cells that incorporated EdU, was observed using a fluorescence microscope (Olympus IX71; Olympus Corporation; magnification, x200).

Flow cytometry analysis. For the analysis of apoptosis, AsPC-1 and PANC-1 cells were seeded at a density of 2x10⁵ cells per well in six-well plates. Cells of NC group were treated with 8 µl DMSO per well. After treatment with IC50 concentration of GSK343 (12.71 µmol/l for AsPC-1; 12.04 µmol/l for PANC-1) and 20 µmol/l of GSK343, cells were harvested and double stained with 5 µl Annexin V-FITC and 5 µl PI (Annexin V, FITC Apoptosis Detection kit; cat. no. AD10; Dojindo Molecular Technologies, Inc.) in the dark. For the assessment of cell cycle distribution, cells were collected and fixed in 75% ethanol overnight at 4°C after treatment with GSK343 for 48 h. Upon completion of treatment, cells were washed with PBS and resuspended in 500 µl of staining solution (Cell Cycle Staining kit; cat. no. CCS012; Hangzhou Multi Sciences Biotech Co., Ltd.) at 37°C for 30 min. Finally, apoptosis and cell cycle distribution were detected using flow cytometry (CYTOMICS FC 500; Beckman Coulter, Inc.). Flowjo software 7.6.1 (FlowJo LLC) and Modifit LT software 3.1 (Verity Software House, Inc.) were used to analyze the data of apoptosis and cell cycle.

Immunofluorescence microscopy. After treatment with IC50 concentration of GSK343 (12.71 µmol/l for AsPC-1; 12.04 µmol/l for PANC-1) for 48 h, AsPC-1 and PANC-1 cells were fixed in 100% methanol for 10 min at -20°C, washed with PBST, blocked using 10% FBS at 37°C for 1 h and subsequently incubated with rabbit polyclonal antibody against LC3B, which includes LCBI and LC3BII (1:100) overnight at 4°C. Fluorochrome-conjugated anti-rabbit IgG (1:100) was added to slides and incubated at 37°C for 1 h, after which DAPI counterstaining was performed at 37°C for 20 min and observations were made using a fluorescence microscope (Olympus IX71; magnification, x400).

Western blot analysis. Western blotting was performed as previously described (29). AsPC-1 and PANC-1 cells were harvested and dissolved in a 100 µl mixture of radioimmunoprecipitation assay lysis buffer (Beyotime Institute of Biotechnology, Inc.) and complete protease inhibitor cocktail (Roche Diagnostics) for 30 min so that total protein could be extracted. Protein concentration was then measured using a BCA protein assay kit (cat. no. 23250; Thermo Fisher Scientific, Inc.). Equal quantities of protein (20 µg) were subsequently separated on 10% NuPAGE Bis-Tris gels (Invitrogen; Thermo Fisher Scientific, Inc.) for electrophoresis and transferred to 0.45 µm PVDF membranes for 60 min. Membranes were then blocked using 5% non-fat milk at 37°C for 1 h and incubated with primary antibodies against GDPH, LC3B, AKT, phospho-AKT, ATG5, mTOR and phospho-mTOR at 1:1000 overnight at 4°C. Membranes were then incubated with horseradish peroxidase-conjugated anti-rabbit or anti-mouse secondary antibodies at 1:2,000 for 1 h at room temperature and protein bands were detected using enhanced chemiluminescence (cat. no. G2014; Wuhan Servicebio Technology Co., Ltd.). Band intensity of LC3B-I and LC3B-II was quantified using Image Lab software 5.2.1 (Bio-Rad Laboratories, Inc.).

Statistical analysis. Data were analyzed using SPSS software 24 (IBM Corp.) and figures were created using GraphPad software 6.0 (GraphPad Software, Inc.). The results were
expressed as the mean ± standard deviation from three independent experiments. A one-way ANOVA was performed followed by a Tukey HSD post-hoc test to make comparisons between multiple groups. Comparisons between two groups were analyzed using a Student's t-test. P<0.05 was considered to indicate a statistically significant result.

Results

GSK343 inhibits cell viability and suppresses cell proliferation. GSK343, an inhibitor of EZH2, has been regarded to be a therapeutic target for various types of cancer. In the present study, the effect of GSK343 on the viability of pancreatic cancer cells (AsPC-1 and PANC-1) was evaluated using an MTT assay. As presented in Fig. 1A, the viability of each pancreatic cancer cell line markedly decreased with increasing GSK343 concentration. The IC50 values of AsPC-1 and PANC-1 (12.71±0.41 and 12.04±1.10 µmol/l) revealed that neither pancreatic cell line exhibited a statistically significant difference between values.

The IC50 was selected as a suitable concentration for pancreatic cancer cell treatment and viability after incubation with GSK343 for 24, 48 and 72 h using a CCK-8 assay. As presented in Fig. 1B, the viability of each pancreatic cancer cell line markedly decreased with increasing GSK343 concentration. The IC50 dose and 20 µmol/l of GSK343 for 48 h. The percentage of EdU-positive cancer cells (in AsPC-1 and PANC-1 lines) decreased markedly after treatment with GSK343 (Fig. 2). Therefore, GSK343 suppressed the proliferation of pancreatic cancer cells in a dose-dependent manner.

GSK343 induces cell apoptosis and G1 arrest. To determine the underlying mechanisms that result in the loss of cell viability and the suppression of cell proliferation, apoptosis and cell cycle distribution were assessed using flow cytometry. AsPC-1 and PANC-1 were treated with different concentrations of GSK343 (0 µmol/l; IC50 for the respective cell lines; 20 µmol/l).

As presented in Fig. 3, the Annexin V-FITC/PI assay results reveal that GSK343 treatment induces significant cell apoptosis compared with the untreated pancreatic cancer cells. One representative result was selected, which is presented in Fig. 3A. In AsPC-1 cells, the IC50 dose and 20 µmol/l of GSK343 increased the percentage of apoptotic cells from 6.86 to 13.31 and 20.11%, respectively. The percentage of PANC-1 apoptotic cells after treatment with GSK343, the IC50 concentration and 20 µmol/l increased from 2.88 to 9.74 and 17.85%, respectively.

In Fig. 4, following GSK343 treatment, an increase in the percentage of cells in G1-phase and a reduction in S-phase cells was observed in AsPC-1 and PANC-1 cells. The IC50 of GSK343 increased the percentage of AsPC-1 and PANC-1 cells in G1-phase from 39.78 to 6.44% and 42.02 to 62.59% (Fig. 4A), respectively. GSK343 (IC50) also reduced the percentage of AsPC-1 and PANC-1 cells in S-phase from 45.15 to 22.32% and 40.94 to 25.03% (Fig. 4A). A concentration of 20 µmol/l of GSK343 decreased the percentage of
AsPC-1 in the G2-phase from 15.07 to 5.44% (Fig. 4A). In Fig. 4B, compared with the NC, the IC50 concentration and 20 µmol/l group exhibited significantly increased percentages of G1-phase cells. However, 20 µmol/l of GSK343 did not lead to an increase of pancreatic cancer cells in the G1 phase compared with the IC50 concentration.

GSK343 induces autophagy in pancreatic cancer cells. Autophagy is a process in which cytoplasmic proteins and organelles are delivered to the lysosome for digestion. Various studies have reported the induction of autophagy by GSK343 in osteosarcoma cells, as well as in breast, liver and colorectal cancer [30-32]. Autophagy induction was analyzed using...
immunofluorescence for microtubule-associated protein 1 light chain 3 (LC3) positive punctate dots in GSK343 treatments. As presented in Fig. 5A, LC3B punctate dots per cell (indicated by the red arrow) were markedly increased after GSK343 (IC50) treatment.

LC3 has been considered to be a crucial component in the elongation and closure of autophagosome membranes. Accompanied with this process, LC3 is converted from LC3-I to LC3-II (33). Therefore, autophagy was assessed using the LC3-II/LC3-I ratio (34). In Fig. 5B, following GSK343 (IC50) treatment, a reduction of LC3B-I in AsPC-1 cell was exhibited, but no significant change was observed in PANC-1 cells. However, LC3B-II was markedly increased in both cell types. Western blot analysis revealed that GSK343 (IC50) treatment significantly increased the ratio of LC3B-II/LC3B-I in AsPC-1 and PANC-1 cells (Fig. 5C).

ATG5, which can form the Atg12-Atg5-Atg16L complex, is also the crucial component of the ubiquitin-like conjugation system and promotes autophagosome formation (35). ATG5 did not reveal any significant change after treatment with GSK343 (IC50) in AsPC-1 or PANC-1 cell lines (Fig. 5B).

**Discussion**

EZH2 has been demonstrated to be highly expressed in malignant tumors, serving a crucial role in the progression of breast, bladder and liver malignancies (19-21). Therefore, inhibitors of EZH2 are of therapeutic interest in cancer research. Distinct from DZNep, a classic EZH2 inhibitor that decreases SAH, GSK343 suppresses EZH2 by competitively binding to a methyl donor, SAM (17,18). In the present study, a significant dose and time-dependent reduction in the cell viability of pancreatic cancer cells by GSK343 was demonstrated. GSK343 also suppressed cell proliferation, induced cell apoptosis and blocked cell cycle progression at the G1-phase. These results are consistent with observations in a variety of different types of cancer and may help to identify a novel therapeutic approach for pancreatic cancer.

Figure 3. GSK343 promoted the apoptosis of AsPC-1 and PANC-1 cells. (A) Apoptotic AsPC-1 and PANC-1 cells were detected by Annexin V/PI double-stained flow cytometry after treatment with 0 µmol/l, IC50, or 20 µmol/l GSK343 for 48 h. (B) Apoptosis rates of AsPC-1 and PANC-1 cells are presented as the mean ± standard deviation, *P<0.05 and **P<0.01. NC, negative control.
Autophagy is an important cellular process that digests endogenous proteins or organelles via lysosomal degradation and is divided into macroautophagy, microautophagy and chaperone-mediated autophagy (37). Several studies have established that autophagy serves a crucial role in cell development and in the maintenance of homeostasis (37, 38). While autophagy can recycle damaged and/or dysfunctional cellular components (organelles and macromolecules) to provide raw materials for cell reconstruction and regeneration, the excessive upregulation of autophagy may result in autophagic cell death, also called type II programmed cell death (38, 39).

mTOR, a highly evolutionarily conserved protein kinase, serves a key role in regulating autophagy and may be associated with epigenetic regulatory mechanisms (40, 41). In the present study, the GSK343 induced autophagy of pancreatic cancer cells was observed using immunofluorescence microscopy and western blot analysis. Although GSK343 induces autophagy in pancreatic cancer, as a direct and selective inhibitor of EZH2, whether EZH2 serves a role in GSK343-induced autophagy is controversial. A previous study demonstrated that EZH2 inhibited autophagy by epigenetically repressing the mTOR signaling pathway (42). However, a previous report also demonstrated that DZNep could not induce autophagy in breast, lung and hepatocellular carcinoma cells, and that the suppression of EZH2 expression was unnecessary for GSK343 to induce autophagy (30). The knockdown of EZH2 by small interfering RNA cannot induce autophagy sufficiently and its overexpression is unable to reduce autophagy, which is induced by EZH2 inhibitors in human colorectal cancer cells (31). GSK343-induced autophagy may be associated with the non-canonical pathway-mediated transcriptional upregulation of LC3B (31). These contrasting results require further investigation into the signaling mechanisms which govern the GSK343 induction of autophagy in a variety different types of cancer.

The AKT/mTOR signaling pathway is activated in different types of cancer and is a critical cellular pathway. Upstream AKT kinase can repress the Tuberous Sclerosis complex (TSC) 1/2 by phosphorylating TSC2 to promote mTOR activity, which regulates cell proliferation, differentiation, apoptosis and metabolism, and inhibits autophagy (40). In the current study, the mechanism of GSK343-induced autophagy in pancreatic cancer cells was investigated. Western blot analysis revealed a reduction in p-AKT and p-mTOR after GSK343 treatment. These results indicated that GSK343-induced autophagy involved the AKT/mTOR-mediated signaling pathway in pancreatic cancer cells. However, the role of GSK343 in the inhibition of the AKT pathway is unclear. A previous study of GSK343 induced cell cycle arrest in the G1 phase of AsPC-1 and PANC-1 cells. (A) Flow cytometry analysis was used to detect cell cycle distribution after treatment with 0 µmol/l, IC50 and 20 µmol/l GSK343. (B) Percentage of AsPC-1 and PANC-1 cells in G1-S-G2-phase are presented as the mean ± standard deviation, **P<0.01. NC, negative control.
has revealed that increasing EZH2 can influence H3K27me3 and DNA methylation across the promoter to silence phosphatase and tensin homolog deleted on chromosome 10, which dephosphorylates phosphatidylinositol 3,4,5-triphosphate to inactivate AKT and mTOR complex 1 (43). Studies have also revealed that EZH2 inhibitors may induce endoplasmic reticulum stress, which negatively regulates the AKT/TSC/mTOR pathway to enhance autophagy (31, 44). Further experiments should be performed to support the mechanism of GSK343-induced autophagy in pancreatic cancer.
