Two-Level discretization techniques for ground state computations of Bose-Einstein condensates

Patrick Henning, Axel Målvist, Daniel Peterseim

May 20, 2013

Abstract

This work presents a new methodology for computing ground states of Bose-Einstein condensates based on finite element discretizations on two different scales of numerical resolution. In a pre-processing step, a low-dimensional (coarse) generalized finite element space is constructed. It is based on a local orthogonal decomposition and exhibits high approximation properties. The non-linear eigenvalue problem that characterizes the ground state is solved by some suitable iterative solver exclusively in this low-dimensional space, without loss of accuracy when compared with the solution of the full fine scale problem. The pre-processing step is independent of the types and numbers of bosons. A post-processing step further improves the accuracy of the method. We present rigorous a priori error estimates that predict convergence rates $H^3$ for the ground state eigenfunction and $H^4$ for the corresponding eigenvalue without pre-asymptotic effects; $H$ being the coarse scale discretization parameter. Numerical experiments indicate that these high rates may still be pessimistic.

1 Introduction

Bose-Einstein condensates (BEC) are formed when a dilute gas of trapped bosons (of the same species) is cooled down to ultra-low temperatures close to absolute zero [10, 23, 19, 20, 38]. In this case, nearly all bosons are in the same quantum mechanical state, which means that they lose their identity and become indistinguishable from each other. The BEC therefore behaves like one 'super particle' where the quantum state can be described by a single collective wave function $\Psi$. The dynamics of a BEC can be modeled by the time-dependent Gross-Pitaevskii equation (GPE) [26, 37, 30], which is a nonlinear Schrödinger equation given by

$$i \hbar \partial_t \Psi = -\frac{\hbar^2}{2m} \Delta \Psi + V \Psi + \frac{4\pi \hbar^2 a N}{m} |\Psi|^2 \Psi.$$ (1)
Here, $m$ denotes the atomic mass of a single boson, $N$ the number of bosons (typically in the span between $10^4$ and $10^7$), $\hbar$ is the reduced Plank’s constant and $V$ is an external trapping potential that confines the system. The nonlinear term in the equation describes the effective two-body interaction between the particles. If the scattering length $a$ is positive, the interaction is repulsive, if it is negative the interaction is attractive. For $a = 0$ there is no interaction and (1) becomes the Schrödinger equation. The parameter $a$ changes according to the considered species of bosons. We only consider the case $a \geq 0$ in this paper.

We are mainly interested in the ground state solution of the problem. This steady state of the BEC is of practical relevance, e.g., in the context of atom lasers [34, 29, 41]. The ansatz $\Psi(x, t) = e^{-i\lambda t}u(x)$, with the unknown chemical potential of the condensate $\lambda$, reduces (1) to the steady-state GPE

$$\frac{-\hbar^2}{2m} \triangle u + V u + \beta |u|^2 u = \lambda u,$$

where $\beta = \frac{4\pi\hbar^2aN}{m}$.

The ground state of the BEC is the lowest energy state of the system and is therefore stable. It minimizes the corresponding energy

$$E(v) = \int_{\mathbb{R}^d} \frac{\hbar^2}{2m} |\nabla v|^2 + V|v|^2 + \frac{\beta}{2} |v|^4$$

amongst all $L^2$-normalized $H^1$ functions. For any $L^2$-normalized minimizer $u$, $\lambda = E(u) + \frac{\beta}{2} \|u\|_{L^4(\mathbb{R}^d)}^4$ is the smallest eigenvalue of the GPE. In this paper, we shall focus on the computation of this ground state eigenvalue. Eigenfunctions whose energies are larger than the minimum energy are called excited states of the BEC and are not stable in general but may satisfy relaxed concepts of stability such as metastability (see [36]).

Numerical approaches for the computation of ground states of a BEC typically involve an iterative algorithm that starts with a given initial value and diminishes the energy of the density functional $E$ in each iteration step. Different methodologies are possible: methods related to normalized gradient-flows [5, 3, 1, 2, 5, 7, 24, 6, 9, 21], methods based on a direct minimization of the energy functional [8, 11], explicit imaginary-time marching [31], the DIIS method (direct inversion in the iterated subspace) [40, 16], or the Optimal Damping Algorithm [14, 12].

We emphasize that, in any case, the dimensionality of the underlying space discretization is the crucial factor for computational complexity because it determines the cost per iteration step. The aim of this paper is to present a low-dimensional space discretization that reduces the cost per step and, hence, speeds up the iterative solution procedure considerably.

In the literature, there are only a few contributions on rigorous numerical analysis of space discretizations of the GPE. In particular, explicit orders of convergence are widely missing. In [44, 17], Zhou and coworkers proved the convergence of general finite dimensional approximations that were obtained by minimizing the energy density $E$ in a finite dimensional subspace of $H^1_0(\Omega)$. This justifies, e.g., the direct minimization approach proposed in [8]. The iteration scheme is not specified and not part of the analysis. The results of Zhou were generalized by Cancès, Chakir and Maday [13] allowing explicit convergence rates for finite element approximations and Fourier expansions. A-priori error estimates for a conservative Crank-Nicolson finite difference (CNFD) method and a semi-implicit finite difference (SIFD) method were derived by Bao and Cai [4].

In this work, we propose a new space discretization strategy that involves a pre-processing step and a post-processing step in standard $P1$ finite element spaces. The
pre-processing step is based on the numerical upscaling procedure suggested by two
of the authors [33] for linear eigenvalue problems. In this step, a low-dimensional
approximation space is assembled. The assembling is based on some local orthogonal
decomposition that incorporates problem-specific information. The constructed space
exhibits high approximation properties. The non-linear problem is then solved in this
low-dimensional space by some standard iterative scheme (e.g., the ODA [14]) with very
low cost per iteration step. The post-processing step is based on the two-grid method
suggest by Xu and Zhou [42]. We emphasize that both, pre- and post-processing,
involve only the solution of linear elliptic Poisson-type problems using standard finite
elements.

We give a rigorous error analysis for our strategy to show that we can achieve
convergence orders of $H^4$ for the computed eigenvalue approximations without any
pre-asymptotic effects. We do not focus on the iterative scheme that is used for solving
the discrete minimization problem. The various choices previously mentioned, e.g., the
ODA [14] are possible.

Our new strategy is particularly beneficial in experimental setups with different
types of bosons, because the results of the pre-processing step can be reused over
and over again independent of $\beta$. Similarly, the data gained by pre-processing can be
recycled for the computation of excited states. Other applications include setups with
potentials that oscillate at a very high frequency (e.g. to investigate Josephson effects
[41, 43]). Here, normally very fine grids are required to resolve the oscillations, whereas
our strategy still yields good approximations in low dimensional spaces reducing the
costs within the iteration procedure tremendously.

2 Model problem

Consider the dimensionless Gross-Pitaevskii equation in some bounded Lipschitz do-
main $\Omega \subset \mathbb{R}^d$ where $d = 1, 2, 3$. Since ground state solutions show an extremely fast
decay (typically exponential), the restriction to bounded domains and homogeneous
Dirichlet condition are physically justified. We seek the minimal eigenvalue $\lambda$ and
the corresponding $L^2$-normalized eigenfunction $u \in H^1(\Omega)$ with

$$
- \text{div} A \nabla u + bu + \beta |u|^2 u = \lambda u \quad \text{in } \Omega,
$$

$$
u = 0 \quad \text{on } \partial \Omega.
$$

The underlying data satisfies the following assumptions:

(a) If $d = 1$, the domain $\Omega$ is an interval. If $d = 2$ (resp. $d = 3$), $\Omega$ has a polygonal
(resp. polyhedral) boundary.

(b) The diffusion coefficient $A \in L^\infty(\Omega, \mathbb{R}^{d \times d})$ is a symmetric matrix-valued function
with uniform spectral bounds $\gamma_{\max} \geq \gamma_{\min} > 0$,

$$
\sigma(A(x)) \subset [\gamma_{\min}, \gamma_{\max}] \quad \text{for almost all } x \in \Omega.
$$

(2)

(c) $b \in L^2(\Omega)$ is non-negative (almost everywhere).

(d) $\beta \in \mathbb{R}$ is non-negative.

The weak solution of the GPE minimizes the energy functional $E: H^1_0(\Omega) \to \mathbb{R}$ given by

$$
E(\phi) := \frac{1}{2} \int_{\Omega} A \nabla \phi \cdot \nabla \phi + \frac{1}{2} \int_{\Omega} b |\phi|^2 + \frac{1}{4} \int_{\Omega} \beta |\phi|^4 \quad \text{for } \phi \in H^1_0(\Omega).
$$
Problem 2.1 (Weak formulation of the Gross-Pitaevskii equation).

Find $u \in H^1_0(\Omega)$ such that $u \geq 0$ a.e. in $\Omega$, $\|u\|_{L^2(\Omega)} = 1$, and

$$E(u) = \inf_{v \in H^1_0(\Omega)} \frac{E(v)}{\|v\|_{L^2(\Omega)}^2}.$$  

It is well-known (see e.g. [30] and [13]) that there exists a unique solution $u \in H^1_0(\Omega)$ of Problem 2.1. This solution $u$ is continuous in $\overline{\Omega}$ and positive in $\Omega$. The corresponding eigenvalue $\lambda := 2E(u) + 2^{-1} \beta \|u\|_{L^4(\Omega)}^4$ of the GPE is real, positive, and simple. Observe that the eigenpair $(u, \lambda)$ satisfies

$$\int_\Omega A \nabla u \cdot \nabla \phi + \int_\Omega bu \phi + \int_\Omega \beta |u|^2 u \phi = \lambda \int_\Omega u \phi$$

for all $\phi \in H^1_0(\Omega)$. Moreover, $\lambda$ is the smallest amongst all possible eigenvalues and satisfies the a priori bound $\lambda < 4E(u)$.

3 Discretization

This section recalls classical finite element discretizations and presents novel two-grid approaches for the numerical solution of Problem 2.1. The existence of a minimizer of the functional $E$ in discrete spaces is easily seen. However, uniqueness does not hold in general. We note that unlike claimed in [44] the uniqueness proof given in [30] does not generalize to arbitrary subspaces of the original solution space.

Remark 3.1 (Existence of discrete solutions). Let $W$ denote a finite dimensional, non-empty subspace of $H^1_0(\Omega)$, then there exists a minimizer $u_W \in W$ with $\|u_W\|_{L^2(\Omega)} = 1$, $(u_W, 1)_{L^2(\Omega)} \geq 0$, and

$$E(u_W) = \inf_{u \in W} E(u).$$

If $(W_i)_{i \in \mathbb{N}}$ represents a dense family of such subspaces, then any sequence of corresponding minimizers $(u_i)_{i \in \mathbb{N}}$ satisfies the a priori bound $\lambda < 4E(u)$.

3.1 Standard Finite Elements

We consider two regular simplicial meshes $T_H$ and $T_h$ of $\Omega$. The finer mesh $T_h$ is obtained from the coarse mesh $T_H$ by regular mesh refinement. The discretization parameters $h \leq H$ represent the mesh size, i.e., $h_T := \text{diam}(T)$ (resp. $H_T := \text{diam}(T)$) for $T \in T_h$ (resp. $T_H$) and $h := \max_{T \in T_h} \{h_T\}$ (resp. $H := \max_{T \in T_H} \{H_T\}$). For $T = T_H, T_h$, let

$$P_1(T) = \{v \in L^2(\Omega) \mid \forall T \in T, v|_T \text{ is a polynomial of total degree } \leq 1\}$$

denote the set of $T$-piecewise affine functions. Classical $H^1_0(\Omega)$-conforming finite element spaces are then given by

$$V_h := P_1(T_h) \cap H^1_0(\Omega) \quad \text{and} \quad V_H := P_1(T_H) \cap H^1_0(\Omega) \subset V_h.$$  

Note that on the fine scale, a different choice of polynomial degree, e.g., piecewise quadratic functions, is possible. This would be a better choice for smooth data that
allows for a regular ground state. Our method and its analysis essentially require the inclusion $H^1_0(\Omega) \supset V_h \supset V_H$.

The discrete problem on the fine grid $T_h$ reads as follows.

**Problem 3.2** (Reference discretization on the fine mesh).

Find $u_h \in V_h$ with $(u_h, 1)_{L^2(\Omega)} \geq 0$, $\|u_h\|_{L^2(\Omega)} = 1$ and

$$E(u_h) = \inf_{v_h \in V_h} E(v_h). \quad (3)$$

The corresponding eigenvalue is given by

$$\lambda_h := 2E(u_h) + 2^{-1}\beta\|u_h\|^4_{L^4(\Omega)}. \quad (4)$$

According to Remark 3.1, $u_h$ is not determined uniquely in general. Moreover, $\lambda_h$ is not necessarily the smallest eigenvalue of the corresponding discrete eigenvalue problem. In what follows, $u_h$ refers to an arbitrary solution of Problem 3.2. It will serve as a reference to compare further (cheaper) numerical approximations with. The accuracy of $u_h$ has been studied in [13]. Under the assumption of sufficient regularity, optimal orders of convergence are obtained (cf. (14)).

### 3.2 Preprocessing motivated by numerical homogenization

The aim of this paper is to approximate the reference solution $u_h$ of Problem 3.2 to a very high accuracy within some low-dimensional subspace of $V_h$. For this purpose, we introduce a two-grid upscaling discretization that was initially proposed in [32] for the treatment of multiscale problems. An application of the framework to nonlinear problems was first discussed in [27] and to linear eigenvalue problems in [33]. This contribution aims to generalize and analyze the methodology to the case of an eigenvalue problem with an additional nonlinearity in the eigenfunction. We emphasize that the co-existence of two difficulties, the nonlinear nature of the eigenproblem itself and the additional nonlinearity in the eigenfunction, requires new essential ideas far beyond simply plugging together existing theories for the isolated difficulties.

Let $\mathcal{N}_H$ denote the set of interior vertices in $T_H$. For $z \in \mathcal{N}_H$ we let $\Phi_z \in V_H$ denote the corresponding nodal basis function with $\Phi_z(z) = 1$ and $\Phi_z(y) = 0$ for all $y \in \mathcal{N}_H \setminus \{z\}$. We define a weighted Clément-type interpolation operator (c.f. [15])

$$I_H : H^1_0(\Omega) \to V_H, \quad v \mapsto I_H(v) := \sum_{z \in \mathcal{N}} v_z \Phi_z \quad \text{with} \quad v_z := \frac{(v, \Phi_z)_{L^2(\Omega)}}{(1, \Phi_z)_{L^2(\Omega)}}. \quad (4)$$

It is easily shown by Friedrichs’ inequality and the Sobolev embedding $H^1_0(\Omega) \hookrightarrow L^6(\Omega)$ (for $d \leq 3$) that

$$a(v, \phi) := \int_{\Omega} A \nabla v \cdot \nabla \phi + \int_{\Omega} b v \phi \quad \text{for} \quad v, \phi \in H^1_0(\Omega)$$

defines a scalar product in $H^1_0(\Omega)$ and induces a norm $\|\cdot\|_{H^1(\Omega)} := \sqrt{a(\cdot, \cdot)}$ on $H^1_0(\Omega)$ which is equivalent to the standard $H^1$-norm.

By means of the interpolation operator $I_H$ defined in (4), we construct an $a$-orthogonal decomposition of the space $V_h$ into a low-dimensional coarse space $V^c_{H,h}$ (with favorable approximation properties) and a high-dimensional residual space $V^f_{H,h}$. The residual or 'fine' space is the kernel of the interpolation operator restricted to $V_h$,

$$V^f_{H,h} := \ker(I_H|_{V_h}). \quad (5.a)$$
The coarse space is simply defined as the orthogonal complement of $V_{H,h}^f$ in $V_h$ with respect to $a(\cdot,\cdot)$. It is characterized via the $a$-orthogonal projection $P^f : H^1_0(\Omega) \to V_{H,h}^f$ onto the fine space given by

$$a(P^f v, \phi) = a(v, \phi) \quad \text{for all } \phi \in V_{H,h}^f.$$ 

By defining $P^c := 1 - P^f$, the coarse space is given by

$$V_{H,h}^c := P^c V_h.$$

A basis of $V_{H,h}^c$ is given by $(P^c \Phi_z)_{z \in N_H}$ with $\dim V_{H,h}^c = \dim V_H$. With this definition we obtain the splitting

$$V_h = V_{H,h}^c \oplus V_{H,h}^f.$$ 

Some favorable properties of the decomposition, in particular its $L^2$-quasi-orthogonality, are discussed in Section 6.2.

The minimization problem in the low-dimensional space $V_{H,h}^c$ reads as follows.

**Problem 3.3** (Pre-processed approximation).

Find $u_H^c \in V_{H,h}^c$ with $(u_H^c, 1) \geq 0$, $\|u_H^c\|_{L^2(\Omega)} = 1$ and

$$E(u_H^c) = \inf_{v^c \in V_{H,h}^c} \{ E(v^c) : \|v^c\|_{L^2(\Omega)} = 1 \}.$$ 

The corresponding eigenvalue in $V_{H,h}^c$ is given by $\lambda_H^c : = 2 E(u_H^c) + 2^{-1} \beta \|u_H^c\|_{L^4(\Omega)}^4$.

**Remark 3.4** (Practical aspects of the decomposition). The assembly of the corresponding finite element matrices requires only the evaluation of $P^f \Phi_z$, i.e., the solution to one linear Poisson-type problem per coarse vertex. This can be done in parallel. Section 3.3 below will show that these linear problems may be restricted to local subdomains centered around the coarse vertices, so that even in a serial computing setup the computational complexity of solving all corrector problems is equivalent (up to factor $|\log(H)|$) to the cost of solving one linear Poisson problem on the fine mesh.

Moreover, this pre-processing step is independent of the parameter $\beta$ which characterizes the species of the bosons. Hence, the method becomes considerably cheaper when experiments need to be carried out for different types and numbers of bosons. A similar argument applies to variations on the trapping potential $b$. Provided that this trapping potential is an element of $H^1(\Omega)$ (in practical applications it is usually even harmonic and admits the desired regularity) the bilinear form $a(\cdot,\cdot)$ (and the associated constructions of $V_{H,h}^f$ and $V_{H,h}^c$) can be restricted to the second order term $\int_\Omega A \nabla v \cdot \nabla \phi$ without a loss in the expected convergence rates stated in Theorems 4.1 and 4.2 below. The trapping potential may then be varied without affecting the pre-processed space $V_{H,h}^c$.

Note that the already assembled coarse space may also be re-used in computations of larger eigenvalues (i.e. not only in the ground state solution).

### 3.3 Sparse approximations of $V_{H,h}^c$

The construction of the coarse space $V_{H,h}^c$ is based on fine scale equations formulated on the whole domain $\Omega$ which makes them expensive to compute. However, \cite{32} shows...
that $P^f \Phi_z$ decays exponentially fast away from $z$. We specify this feature as follows. Let $k \in \mathbb{N}$ denote the localization parameter, i.e., a new discretization parameter. We define nodal patches $\omega_{z,k}$ of $k$ coarse grid layers centered around the node $z \in \mathcal{N}$ by

$$\omega_{z,1} := \text{supp } \Phi_z = \cup \{ T \in \mathcal{T}_H \mid z \in T \},$$
$$\omega_{z,k} := \cup \{ T \in \mathcal{T}_H \mid T \cap \omega_{z,k-1} \neq \emptyset \} \quad \text{for } k \geq 2.$$  

(6)

For all vertices $z \in \mathcal{N}$ and for all $k \in \mathbb{N}$, it holds

$$\| P^f \Phi_z \|_{H^1(\Omega \setminus \omega_{z,k})} \lesssim e^{-(\gamma_{\text{min}}/\gamma_{\text{max}})^{1/2}k} \| P^f \Phi_z \|_{H^1(\Omega)}.$$  

(7)

This motivates the truncation of the computations of the basis functions to local patches $\omega_{z,k}$. We approximate $\Psi_z = P^f \Phi_z \in V_{fH,h}$ from (5.a)-(5.c) with $\Psi_{z,k} \in V_{fH,h}(\omega_{z,k}) := \{ v \in V_{fH,h} \mid v|_{\Omega \setminus \omega_{z,k}} = 0 \}$ such that

$$a(\Psi_{z,k}, v) = a(\Phi_z, v) \quad \text{for all } v \in V_{fH,h}(\omega_{z,k}).$$  

(8)

This yields a modified coarse space $V_{cH,h,k}$ with a local basis

$$V_{cH,h,k} = \text{span}\{ \Phi_z - \Psi_{z,k} \mid z \in \mathcal{N} \}.$$  

(9)

The number of non-zero entries of the corresponding finite element matrices is proportional to $k^d N_H$ (note that we expect $N_H^2$ non-zero entries without the truncation). Due to the exponential decay, the very weak condition $k \approx |\log H|$ implies that the perturbation of the ideal method due to this truncation is of higher order and forthcoming error estimates in Theorems 4.1 and 4.2 remain valid. We refer to [32] for details and proofs. The modified localization procedure from [28] with improved accuracy and stability properties may also be applied.

3.4 Post-processing

Although $u_{cH}$ and $\lambda_{cH}$ will turn out to be highly accurate approximations of the unknown solution $(u, \lambda)$, the orders of convergence can be improved even further by a simple post-processing step on the fine grid. The post-processing applies the two-grid method originally introduced by Xu and Zhou [42] for linear elliptic eigenvalue problems to the present equation by using our upscaled coarse space on the coarse level.

Problem 3.5 (Post-processed approximation). Find $u_{cH} \in V_h$ with

$$\int_{\Omega} A \nabla u_{cH} \cdot \nabla \phi_h + \int_{\Omega} b u_{cH} \phi_h = \lambda_{cH} \int_{\Omega} u_{cH} \phi_h - \int_{\Omega} \beta |u_{cH}|^2 u_{cH} \phi_h$$

for all $\phi_h \in V_h$. Define $\lambda_{cH} := (2E(u_{cH}) + 2^{-1}\beta \|u_{cH}\|_{L^2(\Omega)})^{1/2} \| u_{cH} \|_{L^2(\Omega)}^{-2}$.

Let us emphasize that this approach is different from [18], where the post-precessing problem has a different structure and where classical finite element spaces are used on both scales.

4 A-priori error estimates

This section presents the a-priori error estimates for the pre-processed/upscaled approximation with and without post-processing. Throughout this section, $u \in H^1_0(\Omega)$
denotes the solution of Problem 2.1 and $u_h \in V_h$ the solution of reference Problem 3.2, $u^c_{Hh} \in V^c_{H,h}$ the solution of Problem 3.3 and $u^c_h$ the post-processed solution of Problem 3.5.

The notation $f \lesssim g$ abbreviates $f \leq Cg$ with some constant $C$ that may depend on the space dimension $d$, $\Omega$, $\gamma_{\min}$, $\gamma_{\max}$, $\|b\|_{L^2(\Omega)}$, $\beta$, $\lambda$ and interior angles of the triangulations, but not on the mesh sizes $H$ and $h$. In particular it is robust against fast variations of $A$ and $b$.

**Theorem 4.1** (Error estimates for the pre-processed approximation). Assume that $\|u \circ a_h\|_{H^1(\Omega)} \leq 1$. For $u$ and $u^c_{Hh}$ as above, it holds
\[
\|u \circ a_h - u^c_{Hh}\|_{H^1(\Omega)} \lesssim H^2 \|a_h - u_h\|_{H^1(\Omega)}. 
\]
For sufficiently small $h$ (in the sense of Cancéès et al. [13]), we also have
\[
|\lambda - \lambda^c_{Hh}| \leq \|u \circ a_h - u^c_{Hh}\|_{L^2(\Omega)} \lesssim H^3 + H \|u \circ a_h - u_h\|_{H^1(\Omega)}. 
\]

**Proof.** The proof is postponed to Section 6.3. \hfill \square

The additional post-processing improves, roughly speaking, the order of accuracy by one.

**Theorem 4.2** (Error estimates for the post-processed approximation). Assume that $h$ is sufficiently small. The post-processed approximation $u^c_h$ and the post-processed eigenvalue $\lambda^c_h$ satisfy:
\[
\|u \circ a_h - u^c_h\|_{H^1(\Omega)} \lesssim H^3 \|a_h - u_h\|_{H^1(\Omega)}, 
\]
\[
|\lambda - \lambda^c_h| \leq \|u \circ a_h - u^c_h\|_{L^2(\Omega)} \lesssim H^4 + C_{L^2}(h, H). 
\]

The constant $C_{L^2}(h, H) \approx H^2 \|a - u_h\|_{H^1(\Omega)}$ has a complicated structure and can be extracted from the proofs in Section 6.4.2.

**Proof.** The proof is postponed to Section 6.4. \hfill \square

Let us emphasize that both theorems remain valid for $V^c_{H,h}$ replaced with its sparse approximation $V^c_{H,h,k}$ for moderate localization parameter $k \gtrsim \log H$.

Recall from [13] that for a bounded domain $\Omega$ with polygonal Lipschitz-boundary, $A \in [W^{1,\infty}(\Omega)]^{d \times d}$, and sufficiently small $h$, the fine scale error $\|u \circ a_h - u_h\|_{H^1(\Omega)}$ satisfies the optimal estimate
\[
\|u \circ a_h - u_h\|_{H^1(\Omega)} + h^{-1}\|u \circ a_h - u_h\|_{L^2(\Omega)} + h^{-1}|\lambda - \lambda_h| \lesssim h. 
\]

The proof in [13] is for constant $A = 1$ and hyperrectangle $\Omega$ but it is easily checked that the estimates remain valid for any bounded domain $\Omega$ with polygonal Lipschitz-boundary and $A \in [W^{1,\infty}(\Omega)]^{d \times d}$. Under these assumptions our a priori estimates for the post-processed approximation of the ground state eigenvalue summarize as follows
\[
|\lambda - \lambda^c_h| \lesssim H^4 + H^2 h. 
\]

Hence, in this regular setting, the choice $H = h^{1/2}$ ensures that the loss of accuracy is negligible when compared to the accuracy of the expensive full fine scale approximation $\lambda_h$.

Moreover, note that the fine scale error crucially depends on higher Sobolev regularity of the solution whereas our estimates for the coarse scale error require only minimal regularity that holds under the assumption (a)–(d) in Section 2. Thus, we believe that in a less smooth setting, even coarser choices of $H$ relative to $h$ will balance the discretization errors on the coarse and the fine scale.
5 Numerical experiments

Any numerical approach for the computation of ground states of a BEC involves an iterative algorithm that starts with a given initial value and diminishes the energy of the density functional \( E \) in each iteration step. In this contribution, we use the Optimal Damping Algorithm (ODA) originally developed by Cancès and Le Bris \cite{14, 12} for the Hartree-Fock equations, since it suits our pre-processing framework. The ODA involves solving a linear eigenvalue problem in each iteration step. However, after pre-processing these linear eigenvalue problems are very low dimensional and the precomputed basis of \( V_{c,H} \) can be reused for each of these problems making the iterations extremely cheap. The approximations produced by the ODA are known to rapidly converge to a solution of the discrete minimization problem (see \cite{22} and \cite{12} for a proof in the setting of the Hartree-Fock equations). All subsequent numerical experiments have been performed using MATLAB \cite{35}.

5.1 Numerical results for harmonic potential

As a first example we choose the smooth experimental setup of \cite{13} Section 4, p. 109 and Fig. 2 (bottom)], i.e., \( \Omega := (0, \pi)^2 \), \( b(x_1, x_2) := x_1^2 + x_2^2 \), \( A = 1 \), \( \beta = 1 \) and with homogeneous Dirichlet boundary condition. Consider uniform coarse meshes \( T_h \) with mesh width parameters \( H = 2^{-1}\pi, 2^{-2}\pi, \ldots, 2^{-4}\pi \) of \( \Omega \). The reference mesh \( T_h \) has mesh width \( h = 2^{-7}\pi \) and remains fixed. We study the error committed by coarsening from finescale \( h \) to several coarse scales \( H \), i.e., we study the distance between the discrete reference ground state \( (u_h, \lambda_h) \) and the coarse scale approximation \( (u_{H,h}, \lambda_{H,h}) \) resp. its post-processed version \( (\tilde{u}_{H,h}, \tilde{\lambda}_{H,h}) \). All approximations are computed with the ODA method as presented in \cite{22} Section 2 with accuracy parameter \( \varepsilon_{\text{ODA}} = 10^{-14} \). The localization parameter \( k \) (cf. Section \ref{sec:localization}) is chosen \( k = [4 \log(1/H)] \). Figure \ref{fig:results} reports the results.

Observe that the experimental rates with respect to \( H \) displayed in the figures are
in fact better than predicted in Theorems 4.1 and 4.2. An explanation might be that we have not exploited regularity \( u \in H^3(\Omega) \) of the ground state in our analysis. Similar as in [33, Remark 3.3], additional powers of \( H \) might be possible under such regularity.

Although the reported errors are not the true errors but only the differences compared with the finescale reference solution, we conclude that it would have been sufficient to choose \( H \approx h^{1/3} \) to achieve the accuracy of \( u_h \) in our coarse approximation scheme.

Our implementation is not yet adequate for a fair comparison with regard to computational complexity and computing times between standard fine scale finite elements and our two-level techniques. However, to convince the reader of the potential savings in our new approach, let us mention that the number of iterations of the ODA were basically the same for both approaches in all numerical experiments. This statement applies as well to more challenging setups with larger values of \( \beta \) (see, e.g., Section 5.2 below) where ODA needs many iterations to fall below some prescribed tolerance. We, hence, conclude that the actual speed-up of our approach is truly reflected by the dimension reduction from \( h^{-d} \) to \( H^{-d} \) up to the overhead \( O(k) = O(\log |H|) \) induced by slightly denser (but still sparse) finite element matrices on the coarse level.

### 5.2 Numerical results for discontinuous periodic potential

In the second numerical experiment, we address the case of a BEC that is trapped in a periodic potential. Periodic potentials are of special interest since they can be used to explore physical phenomena such as Josephson oscillations and macroscopic quantum self-trapping of the condensate (c.f. [41, 43]). Here we use a potential \( b \) that describes a periodic array of quantum wells that can be experimentally generated by the interference of overlapping laser beams (c.f. [39]).

Let \( \Omega = (0, \pi)^2 \), \( A = 1 \), and \( \beta = 4 \). Given \( b_t = 100 \) and \( L = 4 \), define

\[
b_0(x_1, x_2) := \begin{cases} 
0 & \text{for } x \in \left[\frac{1}{4}, \frac{3}{4}\right]^2 \\
b_t & \text{else}
\end{cases}
\]

and the potential \( b(x) = b_0 \left( L \left( x/\pi - \left\lfloor Lx/\pi \right\rfloor \right) \right) \).

Consider the same numerical setup as in Section 5.1 with an adaptation of the ODA accuracy parameter \( \varepsilon_{\text{ODA}} = 10^{-8} \). Figure 2 reports the results. Also in this less smooth setting, the experimental rates with respect to \( H \) are better than predicted in Theorems 4.1 and 4.2.

### 6 Proofs of the main results

#### 6.1 Auxiliary results

An application of [13, Theorem 1] shows that \( u_h \) and \( u_c^H \) both converge to \( u \) in \( H^1(\Omega) \), which guarantees stability:

**Remark 6.1** (Stability of discrete approximations). For sufficiently small \( h \) we have

\[
\|u_h\|_{H^1(\Omega)} \leq \sqrt{\lambda_h} \lesssim \sqrt{\lambda} \quad \text{and} \quad \|u_h\|_{L^4(\Omega)} \leq \left( \frac{\lambda_h}{\beta} \right)^{\frac{1}{4}} \lesssim \left( \frac{\lambda}{\beta} \right)^{\frac{1}{4}} .
\]

The same results holds for \( u_h \) replaced by \( u_c^H \) and \( \lambda_h \) replaced by \( \lambda_c^H \).
The bound \([\text{15}]\) is obvious using \(\|u_h\|_{L^2(\Omega)} = 1\) and the \(H^1\)-convergence \(u_h \to u\) which guarantees \(\lambda_h \to \lambda\). Estimate \([\text{16}]\) follows from \(\lambda_h \geq 2E(u_h) \geq \frac{\beta}{2}\|u_h\|^2_{L^4(\Omega)}\).

**Remark 6.2** (\(L^\infty\)-bound). The solution \(u\) of Problem 2.1 is in \(L^\infty(\Omega)\). This follows from the uniqueness of \(u \in H^1_0(\Omega)\) which shows that it is also the unique solution of the linear elliptic problem

\[
\int_\Omega A\nabla u \cdot \nabla \phi + bu\phi = \int_\Omega \tilde{f}\phi \quad \text{for all } \phi \in H^1_0(\Omega),
\]

where \(\tilde{f} := (\lambda u - \beta |u|^3) \in L^2(\Omega)\). Standard theory for linear elliptic problems (c.f. \([\text{25}]\) Theorem 8.15, pp. 189–193) then yields the existence of a constant \(c\) only depending on \(\Omega\), \(d\) and \(\|\gamma_{\min}^{-1}b\|_{L^2(\Omega)}\) such that

\[
\|u\|_{L^\infty(\Omega)} \leq c(\|u\|_{L^2(\Omega)} + \gamma_{\min}^{-1}\|\tilde{f}\|_{L^2(\Omega)}) \lesssim 1 + \|u\|^3_{L^2(\Omega)} \lesssim 1 + \|u\|^3_{H^1(\Omega)}. \tag{17}
\]

### 6.2 Properties of the coarse space \(V_{H,h}^c\)

Recall the local approximation properties of the weighted Clément-type interpolation operator \(I_H\) defined in \([\text{1}]\),

\[
H_T^{-1}\|v - I_H(v)\|_{L^2(T)} + \|\nabla(v - I_H(v))\|_{L^2(\Omega)} \leq C_{I_H}\|\nabla v\|_{L^2(\omega_T)} \tag{18}
\]

for all \(v \in H^1_0(\Omega)\). Here, \(C_{I_H}\) is a generic constant that depends only on interior angles of \(T_H\) but not on the local mesh size and \(\omega_T := \bigcup \{S \in T_H | S \cap T \neq \emptyset\}\). Furthermore, for all \(v \in H^1_0(\Omega)\) and for all \(z \in N\) it holds

\[
\int_{\omega_z} (v - v_z)^2 \leq C_{I_H}H^2\|\nabla v\|^2_{L^2(\omega_z)}, \tag{19}
\]

where \(\omega_z := \text{supp}(\Phi_z)\) and \(v_z\) is given by \([\text{4}]\).
Lemma 6.3 (Properties of the decomposition).
The decomposition of $V_h$ into $V_H$ and $V_{H,h}^c$ (stated in Section 3.2) is $L^2$-orthogonal, i.e.,

$$V_h = V_H \oplus V_{H,h}^c \quad \text{and} \quad (v_h, v^f_{H})_{L^2(\Omega)} = 0 \quad \text{for all} \quad v_H \in V_H, \quad v^f \in V_{H,h}^c. \quad (20)$$

The decomposition of $V_h$ in $V_{H,h}^c$ and $V_{H,h}^f$ is a-orthogonal

$$V_h = V_{H,h}^c \oplus V_{H,h}^f \quad \text{and} \quad a(v^c, v^f) = 0 \quad \text{for all} \quad v^c \in V_{H,h}^c, \quad v^f \in V_{H,h}^f \quad (21)$$

and $L^2$-quasi-orthogonal in the sense that

$$a(v^c, v^f)_{L^2(\Omega)} \lesssim H^2 \|\nabla v^c\|_{L^2(\Omega)} \|\nabla v^f\|_{L^2(\Omega)}. \quad (22)$$

Proof. The proof is verbatim the same as in [33].

The following theorem estimates the error of the best-approximation in the modified coarse space $V_{H,h}^c$.

Lemma 6.4 (Approximation property of $V_{H,h}^c$). For any given $v \in H^1_0(\Omega)$ with $\operatorname{div} A\nabla v \in L^2(\Omega)$ it holds

$$\inf_{v^c \in V_{H,h}^c} \|v - v^c\|_{H^1(\Omega)} \lesssim \|H \operatorname{div} A\nabla v\|_{L^2(\Omega)} + \inf_{v_h \in V_h} \|v - v_h\|_{H^1(\Omega)}. \quad (23)$$

Proof. Given $v$, define $f_v := \operatorname{div} A\nabla v + bv \in L^2(\Omega)$ (since $v \in L^\infty(\Omega)$) and let $v_h \in V_h$ denote the corresponding finite element approximation, i.e.,

$$a(v_h, \phi_h) = (f_v, \phi_h)_{L^2(\Omega)} \quad \text{for all} \quad \phi_h \in V_h. \quad (24)$$

With $v_{h,H}^c := P^c v_h \in V_{H,h}^c$, Galerkin-orthogonality and (18) lead to

$$\|A^{1/2}\nabla (v_h - v_{h,H}^c)\|_{L^2(\Omega)}^2 \leq a(v_h, P^f v_h) = (f, P^f v_h)_{L^2(\Omega)} \lesssim \gamma_{\min}^{-1/2} \|H f_v\|_{L^2(\Omega)} \|A^{1/2}\nabla (v_h - v_{h,H}^c)\|_{L^2(\Omega)}. \quad (25)$$

This, the triangle inequality, and norm equivalences readily yield the assertion.

Next, we show that there exists an element $u^c = P^c u_h$ in the space $V_{H,h}^c$ that approximates $u_h$ in the energy-norm with an accuracy of order $O(H^2)$.

Lemma 6.5 (Decomposition of the reference solution).
Let $(u_h, \lambda_h) \in V_h \times \mathbb{R}$ solve Problem 3.2. Then it holds

$$\|P^c u_h\|_{H^1(\Omega)} \leq \sqrt{\lambda_h},$$

$$\|P^c u_h - u_h\|_{H^1(\Omega)} \leq \|P^f u_h\|_{H^1(\Omega)} \lesssim H^2 + \|u - u_h\|_{H^1(\Omega)},$$

$$(P^c u_h, P^f u_h)_{L^2(\Omega)} \lesssim \left( H^2 + \|u - u_h\|_{H^1(\Omega)}^2 \right) H^2. \quad (26)$$

Proof. Recall $\|\cdot\|_{H^1(\Omega)} := \sqrt{a(\cdot, \cdot)}$. Since $P^c$ is a projection, we have

$$\|P^c u_h\|_{H^1(\Omega)}^2 \leq \|u_h\|_{H^1(\Omega)}^2 = \lambda_h \|u_h\|_{L^2(\Omega)}^2 - \beta \|u_h\|_{L^1(\Omega)}^2 \leq \lambda_h. \quad (27)$$

The $a$-orthogonality of [3] further yields
$\|P^I u_h\|_{H^1(\Omega)}^2 = a(u_h, P^I u) = \lambda_h(u_h, (1 - I_H)P^I u_h)_{L^2(\Omega)} - \beta(|u|^3, P^I u_h)_{L^2(\Omega)}$

$$- \beta(|u|^3 - |u|^3, P^I u_h)_{L^2(\Omega)}. \quad (23)$$

The first term on the right hand side can be bounded using $I_H(P^I u_h) = 0$, the $L^2$-orthogonality \[20\], and the estimates for the weighted Clément interpolation operator \[18\]

$$\lambda_h(u_h, (1 - I_H)P^I u_h)_{L^2(\Omega)} = \lambda_h((1 - I_H)u_h, (1 - I_H)P^I u_h)_{L^2(\Omega)} \lesssim \lambda_h H^2 \|u_h\|_{H^1(\Omega)} \|P^I u_h\|_{H^1(\Omega)}. \quad (24)$$

Since $u \in L^\infty(\Omega)$ we have $\nabla(u^3) = 6u^2 \nabla u \in L^2(\Omega)$ and, hence, the second term on the right hand side of \[23\] can be bounded as follows,

$$\beta \int_\Omega |u|^2 u P^I u_h = \beta((1 - I_H)u^3, (1 - I_H)P^I u_h) \overset{19}{\lesssim} H^2 \|u\|_{L^\infty(\Omega)}^2 \|u\|_{H^1(\Omega)} \|P^I u\|_{H^1(\Omega)} \lesssim H^2 \|u\|_{H^1(\Omega)} \|P^I u\|_{H^1(\Omega)}. \quad (25)$$

Since $u_h^3 - u^3 = (u_h^2 + u_h u + u^2)(u_h - u)$, the third term on the right hand side of \[23\] can be estimated by

$$\beta(|u|^3 - |u|^3, P^I u_h)_{L^2(\Omega)} \lesssim \beta \|u\| + |u_h|^2_{L^2(\Omega)} \|u_h - u\|_{L^2(\Omega)} ((1 - I_H)P^I u_h)_{L^2(\Omega)} \lesssim (\|u - u_h\|_{H^1(\Omega)} + H^2) \|P^I u_h\|_{H^1(\Omega)}. \quad (26)$$

The combination of \[23\]–\[26\] readily yields

$$\|P^I u_h\|_{H^1(\Omega)} \lesssim H^2 + \|u - u_h\|_{H^1(\Omega)}^2.$$

The third assertion follows from the previous ones and

$$(P^c u_h, P^I u_h)_{L^2(\Omega)} = ((1 - I_H)P^c u_h, (1 - I_H)P^I u_h)_{L^2(\Omega)} \lesssim H^2 \|P^c u_h\|_{H^1(\Omega)} \|P^I u_h\|_{H^1(\Omega)}.$$

\[6.3\] Proof of Theorem \[4.1\]

\[6.3.1\] Proof of the $H^1$ error estimate \[10\]

We proceed similarly as in \[13\]. The proof is divided into four steps. In the first step, we derive an estimate for an energy difference. This estimate is used in step two to establish the inequality $\|u_h^c - u\|_{H^1(\Omega)}^2 \lesssim E(u_h^c) - E(u)$. Since $u_h^c$ is a minimizer, we can replace $E(u_h^c)$ by $E(w_h^c)$ in the estimate for an arbitrary $L^2$-normalized $w_h^c \in V_H^c$. In step three, we choose $w_h^c := \frac{P^c u_h}{\|P^c u_h\|_{L^2(\Omega)}}$ and show that the perturbation introduced via normalization is of high order $H^3$. In step four, we use step three to estimate $E(w_h^c) - E(u)$.

**Step 1.** Let $w \in H^1_0(\Omega)$ be arbitrary with $\|w\|_{L^2(\Omega)}$, we show that

$$E(w) - E(u) = \frac{1}{2} a(w - u, w - u) + \frac{\beta}{2} (|u|^2 (w - u), w - u)_{L^2(\Omega)}$$

$$+ \frac{\beta}{4} ((|u|^4 - 2|u|^2|w|^2 + |w|^4, 1)_{L^2(\Omega)} - \frac{1}{2} \lambda \|w - u\|_{L^2(\Omega)}^2. \quad (27)$$
First, using \( \|u\|_{L^2(\Omega)} = \|w\|_{L^2(\Omega)} = 1 \) we get
\[
\lambda(u - w, u - w)_{L^2(\Omega)} = \lambda\|u\|_{L^2(\Omega)}^2 - 2\lambda(u, w)_{L^2(\Omega)} + \lambda\|u\|_{L^2(\Omega)}^2
= -2\lambda(u, w)_{L^2(\Omega)}
= -2\alpha(u, w - u) - 2\beta(\|u\|_{L^2(\Omega)}^2, w - u)_{L^2(\Omega)}.
\]
This yields
\[
a(w, w) + \beta(\|u\|_{L^2(\Omega)}^2, w)_{L^2(\Omega)} - a(u, u) - \beta(\|u\|_{L^2(\Omega)}^2, u)_{L^2(\Omega)}
= a(w, w) - 2a(u, w) + a(u, u)
+ \beta(\|u\|_{L^2(\Omega)}^2, w)_{L^2(\Omega)} - 2\beta(\|u\|_{L^2(\Omega)}^2, u)_{L^2(\Omega)} + \beta(\|u\|_{L^2(\Omega)}^2, u)_{L^2(\Omega)}
= a(w - u, w - u) + \beta(\|u\|_{L^2(\Omega)}^2, w - u)_{L^2(\Omega)} - \lambda\|w - u\|_{L^2(\Omega)}^2.
\]
Plugging this into
\[
2E(w) - 2E(u)
= a(w, w) + \frac{\beta}{2}(\|w\|_{L^2(\Omega)}^2, w)_{L^2(\Omega)} - a(u, u) - \frac{\beta}{2}(\|u\|_{L^2(\Omega)}^2, u)_{L^2(\Omega)}.
\]
gives us \([27]\).

**Step 2.** Using \([27]\) with \( w = u_h^c \) and the fact that there exists some \( c_0 \) (independent of \( H \) and \( h \)) such that \( a(u - u_h^c, u - u_h^c) + ((\|u\|_{L^2(\Omega)}^2 - \lambda)u - u_h^c, u - u_h^c)_{L^2(\Omega)} \geq c_0\|u - u_h^c\|_{H^1(\Omega)}^2 \) (c.f. \([13]\) Lemma 1)), we get
\[
E(u_h^c) - E(u)
= \frac{1}{2}a(u_h^c - u, u_h^c - u) + \frac{\beta}{2}(\|u\|_{L^2(\Omega)}^2, u_h^c - u)_{L^2(\Omega)}
+ \frac{\beta}{4}((\|u\|_{L^2(\Omega)}^2 - 2\|u\|_{L^2(\Omega)}^2)u_h^c)^2 + \|u_h^c\|_{L^2(\Omega)}^4) - \frac{1}{2}\lambda\|u_h^c - u\|_{L^2(\Omega)}^2
\geq \frac{c_0}{2}\|u_h^c - u\|_{H^1(\Omega)}^2 + \frac{\beta}{4}\|u\|_{L^2(\Omega)}^2 - \|u_h^c\|_{L^2(\Omega)}^2.
\]
**Step 3.** Using the result of step two yields
\[
\|u_h^c - u\|_{H^1(\Omega)}^2 \lesssim E(u_h^c) - E(u) \leq E(u_h^c) - E(u)
\]
for any \( L^2 \)-normalized \( u_h^c \in V_H^c \). We choose \( u_h^c := \frac{P^c u_h}{\|P^c u_h\|_{L^2(\Omega)}} \) and observe that we get, with Lemma \([6.5]\) that
\[
\|P^c u_h - u_h^c\|_{L^2(\Omega)} = \left|1 - \frac{\|P^c u_h\|_{L^2(\Omega)}}{\|P^c u_h\|_{L^2(\Omega)}}\right| \leq \|P^c u_h - I_H(P^c u_h)\|_{L^2(\Omega)}
\lesssim H\|P^c u_h - I_H(P^c u_h)\|_{H^1(\Omega)} \lesssim H\|u - u_h\|_{H^1(\Omega)} + H^3
\]
and consequently
\[
\|P^c u_h - u_h^c\|_{H^1(\Omega)} = \left|1 - \frac{\|P^c u_h\|_{L^2(\Omega)}}{\|P^c u_h\|_{L^2(\Omega)}}\right| \|P^c u_h\|_{H^1(\Omega)} \lesssim H\|u - u_h\|_{H^1(\Omega)} + H^3,
\]
where we used \( \|u - u_h\|_{H^1(\Omega)} \lesssim 1 \) (implying \( \|P^c u_h\|_{H^1(\Omega)} \lesssim 1 \) and \( \|P^c u_h\|_{L^2(\Omega)} \gtrsim 1 \).
Step 4. Using again [27] leads to
\[
2E(w_h^c) - 2E(u) = a(u|w_h^c - u, w_h^c - u|_{L^2(\Omega)} + \beta(|u|(|w_h^c - u|, w_h^c - u)_{L^2(\Omega)} + \frac{\beta}{2}(|u|^4 - 2|u|^2|w_h^c|^2 + |w_h^c|^4, 1)_{L^2(\Omega)} - \lambda w_h^c - u)_{L^2(\Omega)}.
\]
It only remains to bound the \(\beta\) terms:
\[
\beta(|u|^2(w_h^c - u, w_h^c - u)_{L^2(\Omega)} + \frac{\beta}{2} \int_\Omega (|u|^2 - |w_h^c|^2)^2 \leq \beta \|u\|_{L^6(\Omega)}^2 \|w_h^c\|_{L^2(\Omega)} \|u - w_h^c\|_{L^6(\Omega)} + \frac{\beta}{2} \|u\|_{L^6(\Omega)}^2 \|u - w_h^c\|_{L^2(\Omega)}^2 \leq \beta \|u - P^c u_h\|_{H^1(\Omega)}^2 + \|P^c u_h - w_h^c\|_{H^1(\Omega)}^2 \lesssim \|u - u_h\|_{H^1(\Omega)}^2 + (\|u - u_h\|_{H^1(\Omega)} + H^2)^2.
\]

6.3.2 Proof of the \(L^2\) error estimate [11]
Let in the following \(c_{\lambda,u} : H^1_0(\Omega) \times H^1_0(\Omega) \to \mathbb{R}\) denote the bilinear form given by
\[
c_{\lambda,u}(v, w) := \int_\Omega A\nabla v \cdot \nabla w + bwv + 3\beta|u|^2vw - \lambda \int_\Omega vw
\]
and define the space
\[
V_u^\perp := \{v \in H^1_0(\Omega) | (v, u)_{L^2(\Omega)} = 0\}.
\]
For \(w \in H^1_0(\Omega)\) we let \(\psi_w \in V_u^\perp\) denote the unique solution (see Lemma 6.6 below) of
\[
c_{\lambda,u}(\psi_w, v_\perp) = (w, v_\perp)_{L^2(\Omega)} \text{ for all } v_\perp \in V_u^\perp.
\]

The subsequent lemma applies the abstract \(L^2\)-error estimate, obtained by Cancèes, Chakir, Maday [13, Lemma 1, Theorem 1, and Remark 2], to our setting.

Lemma 6.6 (Abstract approximation [13]). Let \(h\) be sufficiently small, then
\[
|\lambda - \lambda_H| \lesssim \|u - u_H^c\|_{H^1(\Omega)}^2 + \|u - u_H^c\|_{L^2(\Omega)}
\]
and
\[
\|u - u_H^c\|_{L^2(\Omega)} \lesssim \|u - u_H^c\|_{H^1(\Omega)} \inf_{\psi \in V_H} \|\psi - u\|_{H^1(\Omega)}.
\]
Furthermore, the bilinear form \(c_{\lambda,u}(\cdot, \cdot)\) is a scalar product in \(H^1_0(\Omega)\) and induces a norm that is equivalent to the standard \(H^1\)-norm.
Observe the following equivalence. If \( \psi_w \in V_u^\bot \) solves
\[
\int_{\Omega} A \nabla \psi_w \cdot \nabla v_\bot + b \psi_w v_\bot + \beta 3 |u|^2 \psi_w v_\bot - \lambda \int_{\Omega} \psi_w v_\bot = \int_{\Omega} w v_\bot
\]
for all \( v_\bot \in V_u^\bot \), then it also solves
\[
\int_{\Omega} A \nabla \psi_w \cdot \nabla v + b \psi_w v + \beta 3 |u|^2 \psi_w v - \lambda \int_{\Omega} \psi_w v = 2 \beta (u^3, \psi_w)_{L^2(\Omega)} \int_{\Omega} uv + \int_{\Omega} (w - (w, u)_{L^2(\Omega)}) v
\]
for all \( v \in H_0^1(\Omega) \). This can be easily seen as follows: assume \( \text{div} \ A \nabla \psi_w \in L^2(\Omega) \) (the general result follows by density arguments) and let \( P^\bot : L^2(\Omega) \rightarrow V_u^\bot \) denote the \( L^2 \)-orthogonal projection given by \( P^\bot(v) := v - (v, u)_{L^2(\Omega)} \). Since
\[
\int_{\Omega} (- \text{div} A \nabla \psi_w + b \psi_w + 3 \beta |u|^2 \psi_w - \lambda \psi_w) v^\bot = \int_{\Omega} w v^\bot.
\]
we get
\[
\int_{\Omega} P^\bot (- \text{div} A \nabla \psi_w + b \psi_w + 3 \beta |u|^2 \psi_w - \lambda \psi_w) v = \int_{\Omega} P^\bot(w) v
\]
for all \( v \in H_0^1(\Omega) \). By using the explicit formula for \( P^\bot \) and the definition of \( u \) the reformulated equation follows. Furthermore, since \( \psi_w \in H_0^1(\Omega) \) solves a standard elliptic problem, classical theory (c.f. [25]) applies and we get the \( L^\infty \)-estimate
\[
\|\psi_w\|_{L^\infty(\Omega)} \lesssim (1 + \lambda)\|\psi_w\|_{L^2(\Omega)} + |(|u|^3, \psi_w)| + \|w\|_{L^2(\Omega)} \lesssim (1 + \lambda)\|w\|_{L^2(\Omega)}.
\]
(33)

Lemma 6.7 \((L^2\)-error estimate\). Let \( h \) be sufficiently small and let \( u \) denote the solution of Problem 2.1 \( u^h \) the solution of Problem 3.3 and \( \psi_u - u^h \in V_u^\bot \) denote the solution of (30) for \( w = u - u^h \). Then
\[
\|u - u^h\|_{L^2(\Omega)} \lesssim \left( \min_{\psi_h \in V_h} \frac{\|\psi_u - u^h - \psi_h\|_{H^1(\Omega)}}{|u - u^h|_{L^2(\Omega)}} + H \right) \|u - u^h\|_{H^1(\Omega)}.
\]

In Lemma 6.7 the assumption that \( h \) should be sufficiently small enters by using the \( L^2 \)-estimate (32) from [12]. Note that the coarse mesh size \( H \) remains unconstrained.

**Proof.** We define \( e^c_H := u - u^c_H \). Using Proposition 6.4 and Lemma 6.6 we get
\[
\frac{\|e^c_H\|_{L^2(\Omega)}^2}{\|e^c_H\|_{H^1(\Omega)}^2} \lesssim \|\psi_u - u^c_H - \psi_h\|_{H^1(\Omega)} \lesssim \|\psi_u - u^c_H - \psi_h\|_{H^1(\Omega)} + \|\psi^c_H - \psi_h\|_{H^1(\Omega)}
\]
(34)

for all \( \psi^c_H \in V_{u,h}^c \) and all \( \phi_h \in V_h \). It remains to properly choose \( \psi_h \) and \( \psi^c_H \). The proof is structured as follows. We choose \( \phi_h \in V_h \) to be the fine space approximation of the solution of the adjoint problem (30) and \( \psi^c_H \) is chosen to be the \( a(\cdot, \cdot) \)-orthogonal approximation of \( \psi_h \). This guarantees that \( \psi^c_H - \psi_h \) is in the kernel of our interpolation operator (i.e. \( I_H(\psi^c_H - \psi_h) = 0 \)) and we can estimate the occurring terms while gaining an additional error order of \( H \). The proof is detailed in the following.

Let us choose \( \psi_h := \psi^h_{e_H} \), where \( \psi^h_{e_H} \in V_h \) solves
\[
c_{\lambda, u}(\psi^h_{e_H}, v_h) = 2 \beta (|u|^3, \psi^h_{e_H})_{L^2(\Omega)} \int_{\Omega} uv_h + \int_{\Omega} (e^c_H - (e^c_H, u)_{L^2(\Omega)}) v_h
\]
for all $v_h \in V_h$. The coercivity of $c_{\lambda,u}$ yields that $\psi_{e_H}^h$ is well defined. Next, we define
\[ g(v,w,u) := -\mathcal{B}|u|^2v + \lambda v + 2\beta(|u|^2,v)_{L^2(\Omega)}u + (w,u)_{L^2(\Omega)} \]
and solve for $\psi_{e_H}^{H,c} \in V_{H,h}$ with
\[ \int_{\Omega} A\nabla \psi_{e_H}^{H,c} \cdot \nabla v_H^c + b\psi_{e_H}^{H,c} v_H^c = \int_{\Omega} g(\psi_{e_H}^h, e_H^c, u) v_H^c \]
for all $v_H^c \in V_{H,h}$. Since equally $\psi_{e_H}^h \in V_h$ fulfills
\[ \int_{\Omega} A\nabla \psi_{e_H}^h \cdot \nabla v_h + b\psi_{e_H}^h v_h = \int_{\Omega} g(\psi_{e_H}^h, e_H^c, u) v_h \]
for all $v_h \in V_h$, we obtain by using the $\alpha(\cdot, \cdot)$-orthogonality of $\psi_{e_H}^h$ and $\psi_{e_H}^{H,c}$
\[ a(\psi_{e_H}^h - \psi_{e_H}^{H,c}, \psi_{e_H}^h - \psi_{e_H}^{H,c}) = \int_{\Omega} g(\psi_{e_H}^h, e_H^c, u)(\psi_{e_H}^h - \psi_{e_H}^{H,c}) \]
\[ \leq \int_{\Omega} g(\psi_{e_H}^h, e_H^c, u)(\text{Id} - I_H)(\psi_{e_H}^h - \psi_{e_H}^{H,c}) \]
\[ \lesssim (\lambda ||\psi_{e_H}^h||_{H^1(\Omega)} + ||e_H^c||_{L^2(\Omega)})H||\nabla (\psi_{e_H}^h - \psi_{e_H}^{H,c})||_{L^2(\Omega)}. \]
Since
\[ ||\psi_{e_H}^h||_{H^1(\Omega)} \lesssim c_{\lambda,u}(\psi_{e_H}^h, \psi_{e_H}^h) = (e_H^c, e_H^c)_{L^2(\Omega)}, \]
we get
\[ ||\psi_{e_H}^h - \psi_{e_H}^{H,c}||_{H^1(\Omega)} \lesssim H(||e_H^c||_{L^2(\Omega)} + \lambda ||\psi_{e_H}^h||_{H^1(\Omega)}) \lesssim (1 + \lambda)H||e_H^c||_{L^2(\Omega)}. \]
Combining this estimate with (34) yields
\[ ||u - u_H^c||_{L^2(\Omega)} \lesssim \left( \frac{||u - u_H^c||_{H^1(\Omega)}}{||u - u_H^c||_{L^2(\Omega)}} + \frac{||\psi_{e_H}^h - \psi_{e_H}^{H,c}||_{H^1(\Omega)}}{||u - u_H^c||_{L^2(\Omega)}} \right) ||u - u_H^c||_{H^1(\Omega)} \]
\[ \lesssim \left( \frac{||u - u_H^c||_{H^1(\Omega)}}{||u - u_H^c||_{L^2(\Omega)}} + (1 + \lambda)H \right) ||u - u_H^c||_{H^1(\Omega)} \]
\[ \lesssim \left( \min_{\psi_h \in V_h} \frac{||u - u_H^c - \psi_h||_{H^1(\Omega)}}{||u - u_H^c||_{L^2(\Omega)}} + H \right) ||u - u_H^c||_{H^1(\Omega)}. \]
In the last step we used Céa’s lemma for linear elliptic problems and the fact that the $H^1$-best-approximation in the orthogonal space $V_h^0 \cap V_h$ can be bounded by the $H^1$-best-approximation in the full space $V_h$ (c.f. [13] and equation (40) therein).

Using [10] and Lemma [6.7] we obtain for $e_H^c := u - u_H^c$
\[ ||e_H^c||_{L^2(\Omega)} \lesssim \left( \min_{\psi_h \in V_h} \frac{||u - u_H^c - \psi_h||_{H^1(\Omega)}}{||e_H^c||_{L^2(\Omega)}} + H \right) ||e_H^c||_{H^1(\Omega)} \lesssim (|e_H^0| + H) (|e_H^1| + H^2), \]
where $|e_H^0| := \min_{v_h \in V_h} ||u - v_h||_{H^1(\Omega)}$ and $|e_H^1| := \min_{\psi_h \in V_h} \frac{||u - u_H^c - \psi_h||_{H^1(\Omega)}}{||u - u_H^c||_{L^2(\Omega)}}$. Together with (31) this yields
\[ |\lambda - \lambda_H^c| \lesssim ||e_H^c||_{H^1(\Omega)}^2 + ||e_H^c||_{L^2(\Omega)} \lesssim (|e_H^1| + H^2)^2 + (|e_H^1| + H) (|e_H^1| + H^2) \lesssim H|e_H^1| + H^3. \]
6.4 Proof of Theorem 4.2

6.4.1 Proof of the $H^1$ error estimate (12)

In the first step we derive an error identity and in the second step we estimate the occurring terms. Step 1. Due to the definitions of $u_h$ and $u_h^c$ we get for $v_h \in V_h$

\[ a(u_h - u_h^c, v_h) = \lambda_h(u_h, v_h) - \lambda_H^c(u_h^c, v_h) - \beta(|u_h|_{L^2(\Omega)}^2 + |u_h^c|_{L^2(\Omega)}^2) + \beta(|u_h^c|_{L^2(\Omega)}^2, v_h) + \beta(|u_h^c|_{L^2(\Omega)}^2, v_h). \]

\[ \lambda_h(u_h - u_h^c, v_h) + (\lambda_h - \lambda_H^c)(u_h^c, v_h) + \beta \sum_{i=0}^2 (u_h)^{2-i}(u_h^c)^i(u_h - u_h^c, v_h)_{L^2(\Omega)}. \]

Step 2. The treatment of the first and the second term is obvious. The last term is treated with the Hölder-inequality and the embedding $H^1_0(\Omega) \hookrightarrow L^6(\Omega)$ (for $d \leq 3$):

\[ \sum_{i=0}^2 (u_h)^{2-i}(u_h^c)^i(u_h - u_h^c, v_h)_{L^2(\Omega)} \leq ||u_h||_{L^6(\Omega)}^2 ||u_h - u_h^c||_{L^2(\Omega)} ||v_h||_{L^6(\Omega)} + ||u_h||_{L^6(\Omega)}^2 ||u_h - u_h^c||_{L^2(\Omega)} ||v_h||_{L^6(\Omega)} + ||u_h||_{L^6(\Omega)}^2 ||u_h - u_h^c||_{L^2(\Omega)} ||v_h||_{L^6(\Omega)} \leq \lambda_h(u_h - u_h^c, v_h) \leq (\lambda_h + \lambda_H^c) ||u_h - u_h^c||_{L^2(\Omega)} + \lambda_h - \lambda_H^c. \]

We therefore get with $v_h = u_h - u_h^c$ and the Poincaré-Friedrichs inequality

\[ ||u_h - u_h^c||_{H^1(\Omega)} \leq (\lambda_h + \lambda_H^c) ||u_h - u_h^c||_{L^2(\Omega)} + \lambda_h - \lambda_H^c. \]

This implies (12).

6.4.2 Proof of the $L^2$ error estimate in (13)

Lemma 6.8. Let $v \in H^1_0(\Omega)$ be an arbitrary function with $||v||_{L^2(\Omega)} = 1$ and let $\psi_{u-v} \in V_u^\perp$ denote the corresponding solution of the adjoint problem with

\[ c_{\lambda,u}(\psi_{u-v}, w_\perp) = (u - v, w_\perp)_{L^2(\Omega)} \]

for all $w_\perp \in V_u^\perp$ (c.f. (30)). Then it holds

\[ ||u - v||_{L^2(\Omega)} = c_{\lambda,u}(v - u, \psi_{u-v}) + ||u - v||_{L^2(\Omega)}^2 \int_{\Omega} |u|^2 \psi_{u-v} + \frac{1}{4} ||u - v||_{L^2(\Omega)}^4. \]

The lemma can be proved analogously to an equal result given in [13], pages 99-100 therein.

The following lemma treats the semi-discrete case, i.e. we assume $V_h = H^1_0(\Omega)$. The reason is that the proof of the fully discrete case becomes extremely long and hard to read. We note that the proof of the semi-discrete case analogously transfers to the fully-discrete case with sufficiently small $h$ by inserting additional continuous approximations to overcome the problems produced by the missing uniform bounds for $||u_h||_{L^\infty(\Omega)}$ and $||u_h^c||_{L^\infty(\Omega)}$. For the readers convenience we therefore only prove the case $h = 0$. 
Lemma 6.9 (Estimate (13) for \( h = 0 \)). Assume \( h = 0 \), i.e. that \( V_h = H^1_0(\Omega) \). Accordingly we let \( u_h^c \in H^1_0(\Omega) \) denote the semi-discrete post-processed approximation, i.e. the solution to the problem
\[
\int_\Omega A \nabla u_h^c \cdot \nabla \phi + \int_\Omega b u_h^c \phi = \int_\Omega F \phi - \int_\Omega \beta |u_h^c|^2 u_h^c \phi
\]
for all \( \phi \in H^1_0(\Omega) \) (c.f. Problem 3.5). Then it holds
\[
\|u - u_h^c\|_{L^2(\Omega)} \lesssim H^4.
\]

Proof. We divide the proof into two steps. We want to make use of the error identity in Lemma 6.8 with \( v = u_h^c \). However, \( u_h^c \) is not \( L^2 \)-normalized and therefore no admissible test function in the error identity. In the first step, we therefore show that the normalization only produces an error of order \( H^4 \). In the second step it remains to show that the \( L^2 \)-error between \( u \) and the \( L^2 \)-normalized \( u_h^c \) is also of order \( H^4 \).

Step 1. We show that \( \|u_h^c\|_{L^2(\Omega)} - \|u_h^c\|_{L^2(\Omega)} \lesssim H^4 \), which implies \( 1 - H^4 \lesssim \|u_h^c\|_{L^2(\Omega)} \lesssim 1 + H^4 \) (because of \( \|u_h^c\|_{L^2(\Omega)} = 1 \)).

First observe that \( u_h^c \in H^1_0(\Omega) \) is the solution to a classical elliptic problem, which is why we obtain
\[
\|u_h^c\|_{L^\infty} \lesssim \lambda H \lesssim \lambda.
\]

Since \( a(u_h^c - u_H, v_h^c) = 0 \) for all \( v_h^c \in V_h \), we get \( u_h^c - u_H \in V_h \). Hence
\[
a(u_h^c - u_H, u_h^c - u_h^c) = a(u_h^c, u_h^c - u_H) = \lambda_h^c(u_h^c - u_h^c) - \beta(u_h^c, u_h^c - u_h^c)
\]
\[
\quad = \lambda_h^c(u_h^c - u_h^c) - \beta(u_h^c, u_h^c - u_h^c)
\]
Using \( u_h^c - u_H \in V_h \) and inserting \( I_H(u_h^c) \) and \( I_H(u) \) several times, we get with similar arguments as above and with the previous estimate for \( u_h^c - u \):
\[
\|u_h^c - u_H\|_{H^1(\Omega)} \lesssim H^2
\]
and
\[
\|u_h^c - u_H\|_{L^2(\Omega)} = \|(u_h^c - u_h^c) - I_H(u_h^c - u_H)\|_{L^2(\Omega)} \lesssim H \|u_h^c - u_H\|_{H^1(\Omega)} \lesssim H^3.
\]

Next, we show that \( \|u_h^c\|_{L^2(\Omega)} - 1 \) is of higher order. We start with:
\[
\|u_h^c\|_{H^1(\Omega)}^2 - \|u_H\|_{H^1(\Omega)}^2 = a(u_h^c, u_h^c) - a(u_H, u_H)
\]
\[
\quad = \lambda_h^c(u_h^c, u_h^c) - \beta(u_h^c, u_h^c) - \beta((u_h^c)^2 u_H, u_h^c - u_h^c)
\]
\[
\quad = \lambda_h^c(u_h^c) - I_H(u_h^c) - \beta((u_h^c)^2 u_H, u_h^c - u_h^c)
\]
\[
\quad \lesssim (H^4 + H^6 - \beta((u_h^c)^2 u_h^c, u_h^c - u_H))_{L^2(\Omega)}
\]
Using that \( u_h^c \) is bounded uniformly in \( L^\infty(\Omega) \) we can proceed as in the proof of Lemma 6.5 to show:
\[
\beta((u_h^c)^2 u_h^c, u_h^c - u_H)_{L^2(\Omega)} \lesssim H \|u_h^c\|_{H^1(\Omega)} \|u_h^c - u_H\|_{L^2(\Omega)} \lesssim H^4.
\]
So in summary:

\[ \left| \|u_0^c\|_{H^1(\Omega)}^2 - \|u_H^c\|_{H^1(\Omega)}^2 \right| \lesssim H^4. \]

However, on the other hand:

\[
\lambda_H \left( \|u_H^c\|_{L^2(\Omega)}^2 - \|u_0^c\|_{L^2(\Omega)}^2 \right) = \lambda_H (u_H^c - u_0^c, u_0^c - I_H(u_0^c))_{L^2(\Omega)} - \beta(u_H^c, u_0^c - u_H^c))_{L^2(\Omega)} - \|u_0^c\|^2 + ||u_H^c||^2.
\]

This we can treat with the previous results to get:

\[
\left| \|u_H^c\|_{L^2(\Omega)}^2 - \|u_0^c\|_{L^2(\Omega)}^2 \right| \lesssim H^4.
\]

With \( \|u_H^c\|_{L^2(\Omega)} = 1 \) we get

\[
\left| \|u_H^c\|_{L^2(\Omega)} - \|u_0^c\|_{L^2(\Omega)} \right| \lesssim \left| \|u_H^c\|_{L^2(\Omega)}^2 - \|u_0^c\|_{L^2(\Omega)}^2 \right| \lesssim H^4.
\]

Note that in the last step we used that for any \( a \geq 0 \) it holds \( |1 - a| \lesssim |1 - a^2| \).

**Step 2.** Step 1 justifies the definition of \( \tilde{u}_0^c := \|u_0^c\|_{L^2(\Omega)}^{-1} u_0^c \) which fulfills

\[
\|\tilde{u}_0^c - u_0^c\|_{L^2(\Omega)} = \|u_0^c\|_{L^2(\Omega)} - 1 \|u_0^c\|_{L^2(\Omega)} \lesssim H^4.
\]

Next, we show \( \|u - \tilde{u}_0^c\|_{L^2(\Omega)} \lesssim H^4 \). For this purpose define \( \|u_0^c\|_{L^2(\Omega)}^{-1} \tilde{x}_0^c := \lambda_H \). Then \( \tilde{u}_0^c \in H^1(\Omega) \) solves

\[
\int_{\Omega} A \nabla \tilde{u}_0^c \cdot \nabla \phi + \int_{\Omega} b \tilde{u}_0^c \phi = \tilde{x}_0^c \int_{\Omega} u_H^c \phi - \int_{\Omega} \frac{\beta}{\|u_0^c\|_{L^2(\Omega)}} |u_H^c|^2 u_H^c \phi.
\]

We want to use Lemma 6.8 and denote \( \psi := \psi_{u - \tilde{u}_0^c} \) with \( \psi_{u - \tilde{u}_0^c} \in V^\perp_u \) being the solution of (30) for \( w = u - \tilde{u}_0^c \). We get:

\[
c_{\lambda,u}(\tilde{u}_0^c - u, \psi)
\]

\[
= a(\tilde{u}_0^c - u, \psi) + 3\beta \int_{\Omega} |u|^2 \tilde{u}_0^c \psi - 3\beta \int_{\Omega} |u|^2 u \psi - \lambda(\tilde{u}_0^c, \psi)_{L^2(\Omega)} + \lambda(u, \psi)_{L^2(\Omega)}
\]

\[
= a(\tilde{u}_0^c, \psi) + 3\beta \int_{\Omega} |u|^2 \tilde{u}_0^c \psi - 2\beta \int_{\Omega} |u|^2 u \psi - \lambda(\tilde{u}_0^c, \psi)_{L^2(\Omega)}
\]

\[
= \left( \frac{1 - \|u_0^c\|_{L^2(\Omega)}^2}{\|u_0^c\|_{L^2(\Omega)}^2} + 1 \right) \lambda_H \int_{\Omega} u_H^c \psi - \left( \int_{\Omega} |u_H^c|^2 u_H^c \psi \right)
\]

\[
+ 3\beta \int_{\Omega} |u|^2 \tilde{u}_0^c \psi - 2\beta \int_{\Omega} |u|^2 u \psi - \lambda(\tilde{u}_0^c, \psi)_{L^2(\Omega)}
\]

\[
= \left( \frac{1 - \|u_0^c\|_{L^2(\Omega)}^2}{\|u_0^c\|_{L^2(\Omega)}^2} \right) \lambda_H (u_H^c - |u_H^c|^2 u_H^c, \psi)_{L^2(\Omega)} + (\lambda_H - \lambda)(u_H^c - u, \psi)_{L^2(\Omega)}
\]

\[
= I + III + IV + VI
\]

\[
= II + III + IV + VI
\]

\[
= II + III + IV + VI
\]

\[
= II + III + IV + VI
\]
In the last step we used \((u, \psi)_{L^2(\Omega)} = 0\) and
\[
a^3 - 3ab^2 + 2b^2 = (a - b)^2(a + 2b) \quad \text{for } a, b \in \mathbb{R}.
\]

With (37) we have:
\[
|I| \lesssim \left| 1 - \frac{\|u_0^c\|_{L^2(\Omega)}}{\|u_0^c\|_{L^2(\Omega)}} \right| \lambda_H^2 (1 + \|u_H^c\|_{H^1(\Omega)}^2) \|\psi\|_{L^2(\Omega)} \lesssim H^4 \lambda_H^2 (1 + \lambda_H) \|\psi\|_{H^1(\Omega)}.
\]

For II we use Theorem 6.1 to obtain:
\[
|II| \leq \lambda |\lambda_H - \lambda| \|u_H^c - u\|_{L^2(\Omega)} \|\psi\|_{L^2(\Omega)} \lesssim H^3 \lambda \|\psi\|_{L^2(\Omega)} \leq H^6 \|\psi\|_{H^1(\Omega)}.
\]

For term III we can use equation (36) which gives us
\[
|III| \leq \lambda |(u_H^c - u_0^c, \psi - I_H(\psi))_{L^2(\Omega)}| \lesssim \lambda H^3 \|\psi - I_H(\psi)\|_{L^2(\Omega)} \lesssim H^4 \|\psi\|_{H^1(\Omega)}.
\]

Using (38) we get
\[
|IV| \leq \lambda \|u_0^c - \tilde{u}_0^c\|_{L^2(\Omega)} \|\psi\|_{L^2(\Omega)} \lesssim H^4 \|\psi\|_{H^1(\Omega)}.
\]

Equally we get
\[
|V| \lesssim \left| \|u^2(\tilde{u}_0^c - u_0^c, \psi)_{L^2(\Omega)} \right| \lesssim \|u\|_{L^2(\Omega)} \|\tilde{u}_0^c - u_0^c\|_{L^2(\Omega)} \|\psi\|_{L^2(\Omega)} \lesssim \lambda H^4 \|\psi\|_{H^1(\Omega)}.
\]

To estimate VI we need the \(L^\infty\)-estimate given by (33) which reads
\[
\|\psi_{u - \tilde{u}_0^c}\|_{L^\infty(\Omega)} \lesssim \|\tilde{u}_0^c - u\|_{L^2(\Omega)}, \quad (39)
\]

For \(z \in \mathcal{N}\), let the values \(u_z\) and \(\psi_z\) denote the coefficients appearing in the weighted Clément interpolation of \(u\) and \(\psi\) (c.f. equation (4)). Recall that \(\Phi_z\) denote the nodal basis functions of \(V_H\). Using again (36), \((\Phi_z, u^f)_{L^2(\Omega)} = 0\) for all \(z \in \mathcal{N}\), and the fact that \(u_0^c - u_H^c \in V_{H,h}\), we obtain
\[
|VI| \lesssim \left| \|u^2(u_0^c - u_H^c, \psi)_{L^2(\Omega)} \right| \lesssim \left| ((u - I_H(u))u\psi, u_0^c - u_H^c)_{L^2(\Omega)} + \sum_{z \in \mathcal{N}} (u_z(u - u_z)\psi\Phi_z, u_0^c - u_H^c)_{L^2(\Omega)} + \sum_{z \in \mathcal{N}} (|u_z|^2(\psi - \psi_z)\Phi_z, u_0^c - u_H^c)_{L^2(\Omega)} \right|
\lesssim \|u\|_{L^\infty(\Omega)} \left( 2\|\psi\|_{L^\infty(\Omega)} \|u\|_{H^1(\Omega)} + \|u\|_{L^\infty(\Omega)} \|\psi\|_{H^1(\Omega)} \right) H \|u_0^c - u_H^c\|_{L^2(\Omega)} \lesssim \lambda \|u_0^c - u_H^c\|_{L^2(\Omega)}
\]

For the last term Theorem 6.1 leads to
\[
|VII| \lesssim \|u - u_H^c\|_{H^1(\Omega)} \left( \|u_H^c\|_{L^2(\Omega)} + 2\|u\|_{L^2(\Omega)} \right) \|\psi\|_{H^1(\Omega)} \lesssim H^4 \|\psi\|_{H^1(\Omega)}.
\]

Combining the results for the terms I–VII and using \(\|\psi\|_{H^1(\Omega)} \lesssim \|\tilde{u}_0^c - u\|_{L^2(\Omega)}\) we get
\[
|c, \lambda, (\tilde{u}_0^c - u, \psi)| \lesssim H^4 \|\tilde{u}_0^c - u\|_{L^2(\Omega)}.
\]

Since
\[
\frac{1}{4} \|u - \tilde{u}_0^c\|_{L^2(\Omega)}^2 + \|u - \tilde{u}_0^c\|_{L^2(\Omega)}^2 \int_\Omega |u|^2 u\psi - \tilde{u}_0^c \leq C \lambda u^3 - \tilde{u}_0^c \|_{L^2(\Omega)}
\]
we finally obtain with Lemma 6.8
\[ \|u - \tilde{u}_0\|_{L^2(\Omega)}^2 \lesssim |c_{\lambda,u}(\tilde{u}_0 - u, \psi)| \lesssim H^4 \|\tilde{u}_0 - u\|_{L^2(\Omega)}. \]

With (36) we therefore proved
\[ \|u - u_0\|_{L^2(\Omega)} \lesssim H^4. \]

Proposition 6.10. The $L^2$-error estimate in the fully-discrete case can be proved analogously to the semi-discrete case above. We therefore get for sufficiently small $h$ that
\[ \|u - u_h^e\|_{L^2(\Omega)} \lesssim H^4 + C_{L^2}(h,H), \]
with $C_{L^2}(h,H)$ behaving like the term $H^2 \|u - u_h\|_{H^1(\Omega)}$.

6.4.3 Proof of the eigenvalue error estimate in (13)

Corollary 6.11 (Estimate (13)). Let $u_h^e \in V_h$ denote the solution of the post-processing step defined via Problem 3.5 and let $\lambda_h^e := (2E(u_h^e) + 2^{-1}|u_h^e|_{L^4(\Omega)}^4)|u_h^e|_{L^2(\Omega)}^2$. Then there holds
\[ |\lambda_h - \lambda_h^e| \lesssim \|u_h - u_h^e\|_{H^1(\Omega)}^2 + \|u_h - u_h^e\|_{L^2(\Omega)}. \]

Proof. We have for arbitrary $v_h \in V_h$:
\[
\begin{align*}
\alpha(u_h - v_h, u_h - v_h) + \beta(|u_h|^2(u_h - v_h), u_h - v_h)_{L^2(\Omega)} - \lambda_h(u_h - v_h, u_h - v_h)_{L^2(\Omega)} &= \alpha(v_h, v_h) - \lambda_h(v_h, v_h) + \beta(|u_h|^2 v_h, v_h)_{L^2(\Omega)}.
\end{align*}
\]
This implies with $v_h = u_h^e$
\[
|\lambda_h^e - \lambda_h| = \left| \frac{\alpha(u_h^e, u_h^e) + \beta(|u_h^e|^2 u_h^e, u_h^e)_{L^2(\Omega)} - \lambda_h|u_h^e|_{L^2(\Omega)}^2}{\|u_h^e\|_{L^2(\Omega)}^2} \right|
= \left| \frac{\|u_h - u_h^e\|_{H^1(\Omega)}^2 + \beta(|u_h|^2, (u_h - u_h^e)^2)_{L^2(\Omega)} - \lambda_h\|u_h - u_h^e\|_{L^2(\Omega)}^2}{\|u_h^e\|_{L^2(\Omega)}^2} \right|.
\]
The remaining estimate is straightforward using $(a^2 - b^2) = (a - b)(a + b)$. Note that the last term is the dominating term.

We obtain (13) from Corollary 6.11 and our previous estimates for $\|u - u_h^e\|_{H^1(\Omega)}$ and $\|u - u_h^e\|_{L^2(\Omega)}$.
