(Received February 18, 1997)

Working in a Hamiltonian formulation with $A_0 = 0$ gauge and also in a path integral formulation, we show that the vacuum wave functional of the four-dimensional pure Yang-Mills theory has the form of an exponential of a three-dimensional Yang-Mills action. This result implies that vacuum expectation values can be calculated in Yang-Mills theory but one dimension lower than the original theory. Our analysis reveals that this dimensional reduction results from the stochastic nature of the theory.

§1. Introduction

In spite of considerable success of QCD in describing high energy phenomena, dynamics at low energies, such as confinement and chiral symmetry breaking, has not satisfactorily been understood yet. Nonperturbative approaches are essential to study the low energy dynamics because of the strong coupling nature. One of successful nonperturbative approaches is the lattice formulation. The strong coupling expansion on the lattice has succeeded in showing an area law for Wilson loops. This strong coupling result seems to capture the essence of quark confinement, but a shortcoming of the lattice formulation is that the connection with continuum field theory has been established only numerically. Furthermore, the lattice formulation encounters a notorious fermion doubling problem and it is difficult to use in studying spontaneous chiral symmetry breaking. Thus, it is important to develop nonperturbative methods in the continuum formulation to study the low energy dynamics of nonabelian gauge theories more transparently.

In this paper, we first examine the vacuum structure of pure Yang-Mills theory in the continuum Hamiltonian formulation, which is well suited to study the nonperturbative dynamics of the theory. Our aim is then to solve the ground state of the Schrödinger wave functional equation

$$H\Psi_0[A] = E_0\Psi_0[A], \quad (1.1)$$

where $H$ is the Yang-Mills Hamiltonian. An approximate vacuum wave functional in the infrared regime was originally suggested by Greensite to be of the form

$$\Psi_0[A] = N \exp \left\{ -\frac{\gamma}{g^4} \int d^3x (F^a_{ij})^2 \right\}, \quad (1.2)$$

where $F^a_{ij}$ is a magnetic component of the field strength and $\gamma$ is a numerical constant. This result has been supported by other studies: A lattice version of the...
wave functional (1·2) has been obtained in the strong coupling expansion of the lattice Hamiltonian formulation and also studied using a Monte Carlo method. The wave functional (1·2) has been rederived in the continuum strong coupling expansion by Mansfield. The form of the wave functional (1·2) implies that vacuum expectation values can be calculated in a path integral representation of a three-dimensional Yang-Mills theory. Three-dimensional gauge theories have been studied by various authors. Polyakov has shown that three-dimensional compact QED exhibits a mass gap and confines electric charges. For nonabelian gauge theories in three dimensions, Feynman and, recently, many authors have discussed the existence of a mass gap. Greensite has shown an area law of Wilson loops in an analog gas approximation in his original work. The arguments of the \( D = 4 \rightarrow D = 3 \) dimensional reduction might work again for the resulting three-dimensional Yang-Mills theory and in this case the theory would reduce to a two-dimensional Yang-Mills theory, which exhibits confinement trivially. The vacuum wave functional (1·2) strongly suggests that in a strong coupling regime the vacuum consists of random magnetic fluxes, whose existence has been discussed as a necessary and sufficient condition for confinement.

Although the wave functional (1·2) is a good candidate for the vacuum and possesses the desired properties, none of the previous works have verified that it is actually the vacuum, i.e., the lowest energy state, because they have looked for solutions of the Schrödinger equation (1·1) by taking appropriate ansatzs of the vacuum wave functional. In this paper, we show that the wave functional (1·2) is the lowest energy state in a more convincing way. Our approach reveals that the \( D = 4 \rightarrow D = 3 \) dimensional reduction results from the stochastic nature of the theory: We show that four-dimensional Yang-Mills theory in the infrared regime is equivalently described by the stochastic system

\[
\frac{\partial A^a_i(x, t)}{\partial t} = -\frac{g^2}{2} \frac{\delta S_{\text{YM}}[A]}{\delta A^a_i(x)} \bigg|_{A_i(x) = A_i(x, t)} + \eta^a_i(x, t),
\]

where \( \eta^a_i \) is Gaussian white noise and \( S_{\text{YM}} \) is a three-dimensional Yang-Mills action. In the equilibrium limit \( t \rightarrow \infty \), this system has been shown to be equivalent to the quantum theory with action \( S_{\text{YM}} \).

This paper is organized as follows: In §2, we solve a regularized version of the Schrödinger equation (1·1) and show that the vacuum wave functional takes the form (1·2) in the limit of the cutoff \( s \rightarrow 0 \). In §3, it is shown that the Euclidean four-dimensional Yang-Mills theory can equivalently be described by the Langevin equation (1·3) in the limit \( s \rightarrow 0 \). Section 4 is devoted to a conclusion.

§2. Vacuum wave functional

We shall consider the pure Yang-Mills theory, whose Lagrangian is given by

\[
\mathcal{L} = -\frac{1}{4g^2} F^a_{\mu\nu} F^{\mu\nu a},
\]
where $F^a_{\mu\nu}$ is the field strength defined by

$$ F^a_{\mu\nu} = \partial_\mu A^a_\nu - \partial_\nu A^a_\mu + f^{abc} A^b_\mu A^c_\nu. \tag{2.2} $$

For our purposes, it is convenient to choose the $A_0 = 0$ gauge. In the Schrödinger representation, the (unregulated) Hamiltonian is then given by

$$ H = \int d^3x \left\{ -\frac{g^2}{2} \frac{\delta^2}{\delta A_i^p(x) \delta A_i^p(x)} + \frac{1}{4g^2} \left( F_{ij}^a(x) \right)^2 \right\}. \tag{2.3} $$

Here Latin indices $i$, $j$, $k$, etc. run over the values 1, 2 and 3. In the $A_0 = 0$ gauge, the wave functional $\psi[A]$ must be subject to the Gauss' law constraint,

$$ \left( D_i \frac{\delta}{\delta A_i(x)} \right)^a \psi[A] = 0, \tag{2.4} $$

where $D_i$ denotes a covariant derivative. This constraint simply implies that the wave functional is invariant under time-independent gauge transformations. The Schrödinger equation (1.1) with the Hamiltonian (2.3) requires regularization because it contains a product of two functional derivatives at the same spatial point:

$$ \Delta \equiv \int d^3x \frac{\delta^2}{\delta A_i^p(x) \delta A_i^p(x)}. \tag{2.5} $$

To make the differential operator (2.5) well defined, we replace $\Delta$ by the following differential operator:

$$ \Delta(s) \equiv \int d^3xd^3y \frac{\delta}{\delta A_i^a(x)} K^{ab}_{ij}(x,y;s) \frac{\delta}{\delta A_j^b(y)}. \tag{2.6} $$

The kernel $K^{ab}_{ij}(x,y;s)$ is required to satisfy a heat equation,

$$ \frac{\partial}{\partial s} K^{ab}_{ij}(x,y;s) = \left[ \delta_{ik} \left( D^2(x) \right)^{ac} - (D_i(x)D_k(x))^{ac} - 2f^{acd} F^d_{ik}(x) \right] K^{ab}_{kj}(x,y;s), \tag{2.7} $$

with the initial condition

$$ \lim_{s \to 0} K^{ab}_{ij}(x,y;s) = \delta_{ij} \delta^{ab} \delta^3(x-y). \tag{2.8} $$

Taking $s$ small but nonzero in Eq. (2.6) gives a regularized operator of $\Delta$. (In the naive limit $s \to 0$, $\Delta(s)$ is reduced to $\Delta$.) It should be emphasized that the regularized operator $\Delta(s)$ preserves gauge invariance and (three-dimensional) Lorentz invariance.

The heat equation (2.7) can be solved by a standard technique. Acting with $\Delta(s)$ on three-dimensional integrals of local functions gives an expansion in powers of $s$ and may contain inverse powers of $s$, which diverge as $s \to 0$. These powers of $s$ may be determined from dimensional analysis and gauge invariance. We have, for
example,

\[ \int d^3x d^3y \frac{\delta}{\delta A^a_i(x)} K_{ij}^{ab}(x, y; s) \frac{\delta}{\delta A^b_j(y)} \int d^3z (F_{ki}^c(z))^2 \]

\[ = \int d^3x \left\{ \frac{\alpha_1}{s^{5/2}} + \frac{\alpha_2}{s^{1/2}} (F_{ij}^a)^2 + s^{1/2} \left( \alpha_3 (D_{ij}^a F_{ij}^b)^2 + \alpha_4 f^{abc} F_{ij}^a F_{jk}^b F_{ki}^c \right) + O(s^{3/2}) \right\}, \quad (2.9) \]

where the \( \alpha_n \) are numerical constants. The first two coefficients are given by

\[ \alpha_1 = \frac{3 \text{dim } G}{2 \pi^{3/2}}, \quad \alpha_2 = -\frac{11 C_2(G)}{24 \pi^{3/2}}, \quad (2.10) \]

where \( \text{dim } G \) is the number of generators of the gauge group \( G \), and \( C_2(G) \) is given by \( f^{acd} f^{bcd} = C_2(G) \delta^{ab} \).

We now have a regularized Hamiltonian:

\[ H[A; s] = \int d^3x \left\{ -\frac{g^2}{2} \int d^3y \frac{\delta}{\delta A_i^a(x)} K_{ij}^{ab}(x, y; s) \frac{\delta}{\delta A_j^b(y)} + \frac{1}{4g^2} (F_{ij}^a(x))^2 \right\}. \]

Let us rewrite the regularized Hamiltonian (2.11) into the form

\[ H[A; s] = \int d^3x d^3y \, Q_i^a(x) K_{ij}^{ab}(x, y; s) Q_j^b(y) + \Gamma[A; s]. \]

The operators \( Q_i^a \) and \( Q_i^a \dagger \) are defined by

\[ Q_i^a(x) = i \frac{g}{\sqrt{2}} \left( \frac{\delta}{\delta A_i^a(x)} + \frac{1}{2} \frac{\delta S_{\text{SYM}}[A]}{\delta A_i^a(x)} \right), \]

\[ Q_i^a \dagger(x) = i \frac{g}{\sqrt{2}} \left( \frac{\delta}{\delta A_i^a(x)} - \frac{1}{2} \frac{\delta S_{\text{SYM}}[A]}{\delta A_i^a(x)} \right), \quad (2.13) \]

where

\[ S_{\text{SYM}}[A] = \frac{24 \pi^{3/2} s^{1/2}}{11 C_2(G) g^4} \int d^3x \, (F_{ij}^a(x))^2. \]

A key observation is that \( \Gamma[A; s] \) in Eq. (2.12) vanishes in the naive limit \( s \to 0 \). It is easy to see from the formula (2.9) that \( \Gamma[A; s] \) has the form

\[ \Gamma[A; s] = \int d^3x \left\{ s (\beta_1 (D_{ij}^a F_{ij}^b)^2 + \beta_2 f^{abc} F_{ij}^a F_{jk}^b F_{ki}^c) + O(s^2) \right\}, \quad (2.15) \]

up to a field independent constant. The functional \( \Gamma[A; s] \) contains only higher dimensional terms with positive powers of \( s \). Thus, in the naive limit \( s \to 0 \), \( \Gamma[A; s] \) vanishes* (up to an irrelevant constant). Therefore, in the limit \( s \to 0 \), the Hamiltonian

\[ H[A; s] \]

vanishes. This behavior is consistent with the assumption that \( \Gamma[A; s] \) vanishes as \( s \to 0 \).
Vacuum Wave Functional of Pure Yang-Mills Theory 943

tonian (2-11) may be replaced by

\[ \overline{H}[A;s] = \int d^3x d^3y \, Q^a_i(x)K_{ij}^{ab}(x,y;\sigma)Q^b_j(y), \]  
(2-16)

up to an irrelevant constant. Since the kernel \( K_{ij}^{ab} \) is positive definite, \( \overline{H} \) is positive semi-definite. Thus, a zero energy eigenstate of \( \overline{H} \), if any, is the lowest energy state, i.e., the vacuum,**)

\[ \overline{H}\Psi_0[A] = 0. \]  
(2-17)

It follows from the form (2-16) that the above equation is equivalent to

\[ Q^a_i(x)\Psi_0[A] = 0, \]  
(2-18)

which leads to the solution

\[ \Psi_0[A] = N \exp\left\{ -\frac{1}{2} S_{3YM}[A] \right\}, \]  
(2-19)

as announced in the Introduction. It should be emphasized that we have not assumed any specific form of the vacuum wave functional to derive Eq. (2-19). Since \( S_{3YM} \) in Eq. (2-14) is positive semi-definite, the wave functional \( \Psi_0[A] \) is normalizable, as it should be.

Let \( F[A] \) be any functional of \( A_i^a \). The vacuum expectation value of \( F[A] \) can be expressed as

\[ \int DA_i \Psi_0^*[A]F[A]\Psi_0[A] = N^2 \int DA_i F[A] \exp\left\{ -S_{3YM}[A] \right\}. \]  
(2-20)

The last expression is identical to a path integral representation of the three-dimensional Yang-Mills theory. Vacuum expectation values of any physical operators must be independent of the cutoff \( s \), so that the coupling constant \( g \) should be regarded as a function of \( s \).***) It follows from Eqs. (2-14) and (2-20) that the \( s \) dependence of \( g \) should be given by \( g^4 \propto s^{1/2} \).

\[ g(s)^4 \propto s^{1/2}. \]  
(2-21)

§3. Stochastic quantization point of view

In the previous section, we derived the vacuum wave functional (2-19) in the Hamiltonian formulation. In what follows, we show that the same conclusion (2-19) can be obtained from a stochastic quantization point of view.****

* It should be noted that the naive \( s \to 0 \) limit in Eq. (2-15) can be dangerous. Since \( \Gamma[A;s] \) is not a \( c \)-number but an operator functional, we should take the limit \( s \to 0 \) at the final stage of the computations (i.e., expectation values or correlation functions), and should then justify that \( \Gamma[A;s] \) might be irrelevant in the limit \( s \to 0 \). We will not discuss this point in this paper, but we point out that the justification of Eq. (2-16) needs further consideration.

**) Greensite \(^3\) has found a zero energy solution to the unregulated Hamiltonian. The wave functional is not, however, normalizable and hence does not seem to have a physical meaning.

***) In our field definition (2-2) there is no wave function renormalization.

****) For reviews, see Ref. 15.)
Let us start with the Langevin equation

\[
\frac{\partial A_i^a(x,t)}{\partial t} = -g^2 \frac{\delta S_{3YM}[A]}{2 \delta A_i^a(x)} \bigg|_{A_i(x)=A_i(x,t)} + \eta_i^a(x,t),
\]  

(3.1)

where \( \eta_i^a \) is Gaussian white noise and \( S_{3YM}[A] \) is given in Eq. (2.14). The average over \( \eta_i^a \) is defined by

\[
\langle F[A^a] \rangle_\eta = N' \int D\eta \ F[A^a] \exp \left\{ -\frac{1}{2g^2} \int d^3x dt (\eta_i^a(x,t))^2 \right\},
\]

(3.2)

where \( F \) is an arbitrary function of \( A_i^a \), \( N' \) is a normalization constant, and \( A_i^a \) exhibits \( \eta \) dependence as a solution of the Langevin equation (3.1). We shall now show that the \( \eta \) average (3.2) can be rewritten as

\[
\langle F[A^a] \rangle_\eta = N' \int D\mu \ F[A] \delta(A_0) \exp \left\{ -S_{4YM}[A] \right\},
\]

(3.3)

where \( S_{4YM} \) is the (Euclidean) four-dimensional Yang-Mills action. The right-hand side of Eq. (3.3) is nothing but a path integral representation of Euclidean four-dimensional Yang-Mills theory in the \( A_0 = 0 \) gauge. The equality in Eq. (3.3) should be understood in the same sense that \( H \) in Eq. (2.11) is replaced by \( \tilde{H} \) in Eq. (2.16) in the limit \( s \to 0 \). To show the relation (3.3), we will change the variables from \( \eta_i^a \) to \( A_i^a \) in Eq. (3.2) through Eq. (3.1). Then, the exponent of Eq. (3.2) can be rewritten as

\[
-\frac{1}{2g^2} \int d^3x \int d^3x dt (\eta_i^a(x,t))^2
\]

\[
= -\frac{1}{2g^2} \int d^3x dt \left( \frac{\partial A_i^a(x,t)}{\partial t} + g^2 \frac{\delta S_{3YM}[A]}{2 \delta A_i^a(x)} \bigg|_{A_i(x)=A_i(x,t)} \right)^2
\]

\[
= -\frac{1}{2g^2} \int d^3x dt \left( \frac{\partial A_i^a(x,t)}{\partial t} \right)^2 + O(s),
\]

(3.4)

where we have dropped a total derivative term in the last equality. We next calculate the Jacobian. We have

\[
\det \left( \frac{\delta \eta_i^a}{\delta A_j^a} \right) = \det \left( \frac{\partial}{\partial t} + \frac{g^2}{2} \frac{\delta^2 S_{3YM}[A]}{\delta A_i^a \delta A_j^b} \right)
\]

\[
= \exp \left\{ \int d^3x dt \frac{g^2}{4} \frac{\delta^2 S_{3YM}[A]}{\delta A_i^a(x) \delta A_j^b(x)} \bigg|_{A_i(x)=A_i(x,t)} \right\},
\]

(3.5)

where we have chosen the retarded Green's function of \( \frac{\partial}{\partial t} \) to show the last equality in Eq. (3.5).\(^{15}\) and omitted a field independent constant in Eq. (3.5). The expression

\(^{15}\) In Eqs. (3.4), (3.6) and (3.7), we have not taken account of the \( s \) dependence of the gauge coupling \( g \) given in Eq. (2.21). Even if the \( s \) dependence of \( g \) has been taken into account, the leading terms shown in Eqs. (3.4), (3.6) and (3.7) are still correct.
on the right-hand side of Eq. (3·5) is, however, ill-defined because it contains a product of two functional derivatives at the same spatial point, as found in the Hamiltonian (2·3). According to the prescription discussed in the previous section, we will regularize the product of two functional derivatives. The regularized Jacobian is then given by

\[
\det \left( \frac{\delta \eta^a_i}{\delta A_j^a} \right)_{\text{reg}} = \exp \left\{ - \frac{1}{2g^2} \int d^3x dt \left( \frac{g^2}{2} \frac{\delta S_{\text{YM}}[A]}{\delta A_i^a} \right)^2 \right\}
\]

\[
= \exp \left\{ - \int d^3x dt \frac{1}{4g^2} \left( F_{ij}(x,t) \right)^2 + \mathcal{O}(s) \right\},
\]

where we have used the formula (2·9) and ignored an irrelevant constant. Combining Eqs. (3·4) and (3·6), we finally arrive at the conclusion (3·3), i.e.,

\[
\langle F[A^a_0] \rangle_\eta = N' \int \mathcal{D}A_\mu F[A] \delta(A_0) \exp \left\{ - \frac{1}{2g^2} \int d^3x dt \left( \frac{g^2}{2} S_{\text{YM}}[A] \right)^2 \right\}
\]

\[
\propto \int \mathcal{D}A_\mu F[A] \delta(A_0) \exp \left\{ - \int d^3x dt \left( \frac{1}{2g^2} (A_i^a)^2 + \frac{1}{4g^2} (F_{ij}^a)^2 + \mathcal{O}(s) \right) \right\}
\]

\[
= \int \mathcal{D}A_\mu F[A] \delta(A_0) \exp \left\{ - \int d^3x dt \left( \frac{1}{4g^2} (F_{\mu\nu}^a)^2 + \mathcal{O}(s) \right) \right\}.
\]

Thus, we may conclude that the four-dimensional Yang-Mills theory can equivalently be described by the stochastic system governed by the Langevin equation (3·1). As seen above, \( t \) in the Langevin equation (3·1) corresponds to the Euclidean time, though \( t \) is usually regarded as a fictitious time in a stochastic quantization point of view.\(^{15}\)

In operator language, the right-hand side of Eq. (3·3) may be written as

\[
N' \int_{A_\mu(T)=A_\mu(0)} \mathcal{D}A_\mu F[A] \delta(A_0) \exp \left\{ - \int d^2x \int_0^T dt \frac{1}{4g^2} (F_{\mu\nu}^a)^2 \right\} = \text{Tr} \left( F[A] e^{-T\mathcal{H}} \right),
\]

where we have chosen the periodic boundary condition \( A_\mu^a(T) = A_\mu^a(0) \). Taking the limit \( T \to \infty \) gives

\[
\lim_{T \to \infty} \text{Tr} \left( F[A] e^{-T\mathcal{H}} \right) = \lim_{T \to \infty} \sum_n e^{-TE_n} \langle n | F[A] | n \rangle
\]

\[
\simeq \lim_{T \to \infty} e^{-TE_0} \langle 0 | F[A] | 0 \rangle
\]

\[
= \int \mathcal{D}A_\mu \Psi_0^*[A] F[A] \Psi_0[A].
\]

On the other hand, the Parisi-Wu dimensional reduction implies that the left-hand
side of Eq. (3.3) is reduced to
\[ \lim_{T \to \infty} \langle F[A^n] \rangle_{\eta} = \lim_{T \to \infty} N' \int D\eta_i \int_0^T dt \exp \left\{ -\frac{1}{2g^2} \int d^3 x \int_0^T dt (\eta_i)'^2 \right\} \]
\[ = N' \int DA_i F[A] \exp \{-S_{YM}[A]\} . \] (3.10)

Comparing Eq. (3.9) with Eq. (3.10), we arrive at the same vacuum wave functional (2.19) that we have derived in the Hamiltonian formulation. We therefore conclude that the vacuum wave functional (2.19) results from the stochastic nature of the theory. It is interesting to note that if we regard the Langevin equation (3.1) as a mapping of \( A_i^n \) to \( \eta_i^n \), it is a kind of Nicolai mapping,\(^{18,19} \) which implies the existence of a hidden supersymmetry.\(^{19} \)

§4. Conclusion

We have shown that the vacuum wave functional has the form (2.19) in the naive limit \( s \to 0 \). This does not, however, mean that the wave functional (2.19) is an exact expression for the vacuum, as discussed in Ref. 3). We have dropped higher dimensional terms because they are proportional to positive powers of \( s \) and hence might vanish in the limit \( s \to 0 \). Taking the naive limit \( s \to 0 \) can, however, be dangerous because the scaling behavior in Eq. (2.21) is different from what one expects in the weak coupling regime. This situation seems to be similar to what one finds in the strong coupling expansion of the lattice gauge theory.\(^{1} \) Although we believe that our results are qualitatively correct, it is important to show how our results connect with the weak coupling regime of the theory to make our analysis quantitative.

Finally, we would like to make a comment on dimensional reduction. A simple picture of confinement has previously been proposed;\(^{20,12} \) Random magnetic fluxes are dominating field configurations in a confining QCD vacuum, and the theory exhibits Parisi-Sourlas dimensional reduction of the type \( D = 4 \to D = 2 \)\(^{21} \) in the infrared regime. It is well known that two-dimensional QCD trivially confines. Numerical studies have supported this idea.\(^{22} \) Our observation in the previous section may be a simple realization of the above idea by successively applying our analysis to obtain the \( D = 4 \to D = 3 \to D = 2 \) dimensional reduction, though what we found in this paper is not the Parisi-Sourlas type but the Parisi-Wu type of dimensional reduction.\(^{22} \) It would be of great interest to investigate low energy dynamics of nonabelian gauge theories from a stochastic quantization point of view further.

\(^{18} \) Claudson and Halpern\(^ {16} \) have given different Nicolai maps for Yang-Mills theory in four dimensions, based on the Chern-Simons action, which have been explicitly checked to all orders by Bern and Chan.\(^ {17} \) The connection with our results, however, is unclear.

\(^{19} \) Recently, Kalkkinen and Niemi\(^ {23} \) have discussed the Parisi-Sourlas dimensional reduction in the instanton approximation. The connection with our results is, at this time, unclear.
