Simultaneous bilateral neck of femur fractures following electric shock injury is rare; however, co-existence of hypovitaminosis-D in the Indian population seems to be an emerging threat to the treating orthopaedic surgeon and has to be addressed promptly and effectively.

**Introduction:** Simultaneous bilateral fractures of the neck of femur are rare. Hypocalcemia, epilepsy, osteoporosis, and electrical injuries are known to cause similar injuries.

**Case Report:** We report a case of a 43-year-old male who sustained an electrical shock injury following which he fell from a height of around 4 feet. Radiological studies confirmed bilateral transcervical neck of femur fracture. Laboratory investigations revealed the patient had extremely low levels of vitamin D (11.1 ng/ml). Patient was treated with three 6.5 mm cannulated cancellous screws on each side. Patient had good functional outcome at the end of one year.

**Conclusion:** We report this case as a rare etiological combination of hypovitaminosis-D and electrical injury causing bilateral neck of femur fracture. Such injuries should be diagnosed at the earliest and goal of treatment should be to preserve both the hip joints. Early management would avoid potential complications like non-union and avascular necrosis.

**Keywords:** bilateral neck of femur fracture, electrocution injury, hypovitaminosis-D

**Introduction**
Simultaneous bilateral fractures of neck of femur are rare. The reasons behind such injuries are varied. Electrical shock forms an exceedingly rare cause of bilateral neck of femur fracture. Less than ten cases have been reported in our review of literature [1]. The reason for such an injury is due to violent unopposed muscle contractions rather than the trauma of fall per se. We report a case of simultaneous bilateral fractures of neck of femur occurring due to a rare etiological combination of hypovitaminosis-D and electrical shock injury.

**Case Report**
A 43-year-old male patient presented to the emergency department with a fall from a height of 4 feet. He gave a history of charging his mobile, standing on a shelf of four feet height following which he suffered an electrocution injury. He fell down from the shelf, after which he was unable to stand up on his feet or move his legs due to pain. On examination, his bilateral lower limbs were externally rotated and both hip movements were extremely painful. Radiographic studies confirmed the diagnosis of bilateral transcervical neck of femur (Fig. 1). Investigations revealed his vitamin D levels were low (11.1 ng/ml). The patient was taken up for surgery, closed reduction and internal fixation by 6.5 mm cannulated cancellous screws.

**Surgical technique:**
The patient was operated on the same day. The fracture was reduced by Leadbetter’s technique and reduction was maintained using traction table. Using the lateral approach, the tensor fascia lata was dissected and the area 2.5 cm distal to the vastus ridge was chosen for inserting three 6.5 mm cannulated cancellous screws with washers. After screws were inserted, reduction was checked again with the aid of C-arm. The traction was released before final tightening of the screws. The left hip was fixed by the inverted triangle pattern of screw fixation, whereas the right hip was fixed with upright triangle pattern of fixation (Fig. 2). The post-operative period was uneventful. The patient was taught static quadriceps exercises and active knee and ankle range of movements 5 days after surgery. Active hip movements were initiated six weeks after surgery. Patient was...
If the patient is conscious, a thorough clinical examination should suffice to rule out the above mentioned injuries. In our case, the patient was conscious and unable to lift both legs with painful range of movement of both hips. Hence, it was relatively easy to confirm the diagnosis after radiological studies. If the patient is not conscious, it becomes critical to screen the spine, pelvis and shoulders.

Bilateral neck of femur fractures are difficult to treat if not diagnosed early. Hip preservation should be the goal of treatment in young patients such as in our case. We took a decision of fixing both the femurs with three cannulated cancellous screws each. Dynamic hip screw can also be used as an alternative to treat such injuries. In older patients with a sedentary life style, bilateral hemiarthroplasty can be performed as a salvage procedure [7]. Anesthetic complications like difficult intubation due to spasm or persisting cardiac abnormalities like arrhythmias are usually encountered. In such cases, surgery is deferred until the patient is stabilized. In our case no such complication was encountered.

Complications like non-union and avascular necrosis are very common if neglected and hence the need to diagnose such injuries at the earliest [7, 8]. Our patient was free of complications at the end of one year follow up. He was ambulatory and had good range of movements of the hip, knee and ankle to continue his normal life.

Conclusion

We report this case as a rare etiological combination of hypovitaminosis D and electrical injury causing bilateral neck of femur fracture. Such injuries should be diagnosed at the earliest and goal of treatment should be to preserve both the hip joints. Early management would avoid potential complications like non-union and avascular necrosis.

Clinical Message

The goal of the treatment should be to preserve both the hip joints with prior importance in treating Hypovitaminosis-D, which would help in early healing of fracture and also prevent further pathological fractures following trivial trauma.
