Received September 13, 2018; accepted December 20, 2018

Liver regeneration is a very complex process and is regulated by several cytokines and growth factors. It is also known that liver transplantation and the regeneration process cause massive oxidative stress, which interferes with liver regeneration. The placenta is known to contain various physiologically active ingredients such as cytokines, growth factors, and amino acids. In particular, human placenta hydrolysate (hPH) has been found to contain many amino acids. Most of the growth factors found in the placenta are known to be closely related to liver regeneration. Therefore, in this study, we investigated whether hPH is effective in promoting liver regeneration in rats undergoing partial hepatectomy. We confirmed that cell proliferation was significantly increased in HepG2 and human primary cells. Hepatocyte proliferation was also promoted in partial hepatectomized rats by hPH treatment. hPH increased liver regeneration rate, double nucleic cell ratio, mitotic cell ratio, proliferating cell nuclear antigen (PCNA), and K-67 positive cells in vivo as well as interleukin (IL)-6, tumor necrosis factor alpha (TNF-α), and hepatocyte growth factor (HGF). Moreover, Kupffer cells secreting IL-6 and TNF-α were activated by hPH treatment. In addition, hPH reduced thiobarbituric acid reactive substances (TBARS) and significantly increased glutathione (GSH), glutathione peroxidase (GPx), and superoxide dismutase (SOD). Taken together, these results suggest that hPH promotes liver regeneration by activating cytokines and growth factors associated with liver regeneration and eliminating oxidative stress.

Key words liver regeneration; placenta; partial hepatectomy; cytokine; anti-oxidative stress

INTRODUCTION

The liver plays a central role in metabolic homeostasis because it is responsible for the metabolism, synthesis, storage, and redistribution of nutrients such as carbohydrates, fats, and vitamins.1,2) Hepatocytes perform most of the functions of the liver. Moreover, the liver is a unique organ that has the ability to grow and regenerate.3) Although adult hepatocytes are long-lived and do not undergo cell division under normal conditions, the proliferative capacity and adaptive abilities of hepatocytes exist even under different metabolic conditions and in the event of hepatic resections or living donor liver transplantation.2,4) These cellular activities and adaptive ability are promoted with decreased volume of liver tissue.5) When this fundamental proliferative ability is not sufficient to compensate for the resected liver, postoperative liver failure occurs, which is a serious complication and remains an important clinical problem.6) To overcome this issue, therapeutic methods that support liver regeneration must be explored. However, few treatment options are capable of enhancing liver regeneration in clinical settings, despite widespread interest and numerous trials.7)

The placenta is a rich source of many biological components, including hormones, cytokines, chemokines, and growth factors.8,9) Many of these factors possibly act in an autocrine and/or paracrine fashion within the human placenta and regulate the production of other biologically active substances, which may hold potential for therapeutic agents as suggested in previous studies, where fractions of human placenta hydrolysate (hPH) stimulated tissue repair processes.9,10) Over the last few decades, hPH has been prescribed clinically to treat chronic hepatitis,12,13) liver cirrhosis14) and other hepatic diseases.15) hPH reportedly ameliorated hepatic injury through liver regeneration9) and inhibited inflammatory reactions and apoptosis.16) Kong and Park recently reported that injection of hPH improved the health status of elderly Koreans.17) Moreover, hPH decreased the levels of serum transaminases (aspartate aminotransferase (AST) and alanine aminotransferase (ALT)).18) Although pseudolobule formation caused by CCl₄ was unaffected by hPH, intravenous injection of hPH minimized the lipid deposition and pathological changes.19) In another study, the histological efficacy of hPH was better in obese patients than in non-obese ones, and no adverse events were observed during the study.12) Because it is safe and well tolerated, the use of hPH was suggested to be potentially effective for the treatment of liver diseases However, the mechanisms underlying the therapeutic effects of hPH remain unexplored.

Although it has not yet been studied with specific growth factor or cytokine-regulated signal transduction pathways,
MATERIALS AND METHODS

**hPH Preparation**  hPH (Laennec, Green Cross WellBeing Corp., Seongnam, Korea) was prepared by the hydrolysis of human placenta using HCl and pepsin.

**Radical Scavenging Activity and Lipid Peroxidation**

**Inhibitory Effect of hPH**  1,1-Diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity was measured as follows: 10 µL of diluted hPH, dissolved in distilled water (DW), was prepared in a 96 well plate, and then 190 µL of 200 mM DPPH, dissolved in methanol, was added. The mixture was incubated at room temperature for 30 min and the absorbance of the reaction mixture was measured at 517 nm. DPPH radical scavenging activity (%) was expressed as follows:

\[
\text{% scavenging} = \frac{\text{control absorbance} - \text{sample absorbance}}{\text{control absorbance}} \times 100
\]

Malondialdehyde (MDA) was measured as a marker of lipid peroxidation. The brains of male Sprague-Dawley (SD) rats were dissected and homogenized in phosphate buffered saline at a ratio of 1:10 (w/v). The homogenate was centrifuged at 1600 × g for 20 min at 4°C. Five hundred microliters of the supernatant was then taken and incubated with 0.3 mL of hPH at different concentrations, 0.1 mL of 50 µM FeCl₃, and 0.1 mL of 0.1 mM ascorbic acid at 37°C for 30 min. The color of the MDA-thiobarbituric acid (TBA) complex was detected at 532 nm. The percent inhibition was calculated using the following formula:

\[
\% \text{Inhibition} = \frac{\text{control absorbance} - \text{sample absorbance}}{\text{control absorbance}} \times 100
\]

**HepG2 Cell and Human Primary Hepatocyte Proliferation**

HepG2 hepatocarcinoma cells were purchased from the American Type Culture Collection (ATCC, Manassas, VA, U.S.A.), and human primary hepatic cells were purchased from Biopredic International (#HEP1870, Paris, France). The HepG2 cells were maintained as a monolayer in RPMI medium supplemented with 10% fetal bovine serum (FBS) and 1% penicillin (100 U/mL)–streptomycin (100 µg/mL) in humidified 5% CO₂ atmosphere at 37°C. Hepatocytes were maintained as a monolayer, and the medium and culture method were in accordance with the protocol provided by the manufacturer. Cell proliferation was measured by the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) reduction method. HepG2 were synchronized by serum starvation for 24 h. The 10% FBS and serially diluted hPH samples were added to the medium at a ratio of 1:9 and cultured for 24 h. After incubation, 5% MTT solution was added and cultured at 37°C for 2 h. The absorbance was measured at 540 nm using a spectrophotometer (Molecular devices plus 384, U.K.). Cell proliferation of human primary hepatocytes was also analyzed by the MTT assay using the same procedure used to analyze the HepG2 cells; however, serum starvation was not performed for hepatocytes. After starvation for 18 h, HepG2 cells were treated with various concentrations of IL-6 (12.5, 25, 50, and 100 ng/mL) with or without 1 µg/mL LMT-28 (Sigma-Aldrich, Cat. No.; SML1628) and incubated for 48 h. In addition, after starvation for 18 h, the cells were treated with various concentrations of hPH (3, 6, and 9 µg/mL) with or without 1 µg/mL LMT-28 and incubated for 48 h. The proliferation of HepG2 cells was analyzed by the MTT assay as described above.

**Analysis of Cytokines and Growth Factors in Supernatant of Human Primary Hepatocyte**

The concentrations of IL-6 in hepatocyte supernatants were analyzed. The 3rd dilution was selected as the concentration of hPH as it showed the highest efficacy identified in the cell proliferation test. Samples were obtained at 1, 2, 4, 8, 12, and 24 h after treatment with the diluted hPH and analyzed with the Luminex 200 System (Luminex, Austin, TX, U.S.A.)

**Western Blot Analysis**

Extracellular signal-regulated kinase (ERK) and signal transducer and activator of transcription 3 (STAT3) were measured by phosphorylation status using hepatocyte lysates. Western blot analysis was performed according to standard procedures using antibodies specific for Erk1/2, phospho-Erk1/2; Thr202/Tyr204, phospho-STAT3, and phospho-STAT3; Tyr705. All antibodies were purchased from Cell Signaling Technology Inc. (Danvers, MA, U.S.A.). Images were captured and band intensity was quantified by densitometry using the Image J 1.41 software (NIH, Bethesda, MD, U.S.A.).

**Liver Regeneration Effect of hPH in Rats after Partial Hepatectomy**

A total of 90 healthy male SD-rats, weighing 280–330 g each, were randomly divided into six groups. Each group was sub-divided into three groups, 1-d, 3-d, and 5-d according to the autopsy schedule (Table 1). hPH was administered at 1.8 or 3.6 mg/kg body weight once daily subcutaneously before the autopsy, including 2d before surgery, and was administered 30 min before the PHx. Losartan, as a
positive control drug, was orally administered at 5 mg/kg body weight for 30 min before PHx and was administered once daily until autopsy. Median lobes and left lobes, accounting for about 70% of the size of the liver of each SD rat, were excised. Hepatic resection was performed according to the Higgins and Anderson method.\textsuperscript{28} The excised liver tissue was weighed and used for the liver regeneration rate analysis. All the experimental procedures were checked and approved by the Institutional Animal Care and Use Committee (IACUC) of the Hoseo University (Approval No.: HTRC-16-96(1)).

Liver Regeneration Ratio/Serum Analysis Liver regeneration rates were calculated using resected liver weight and autopsy liver weight. The total liver weight was calculated as 70% of the median and left lobes. The liver weights were measured at days 1, 3, and 5 after PHx. However, the liver regeneration rate of the sham group was expressed as the ratio of the sum of the weights of the right and caudate lobes to the total liver weight measured at sacrifice.

Liver regeneration rate = \frac{\text{liver weight at sacrifice}}{\text{resected liver weight} \times \left(\frac{100}{70}\right)} \times 100

The blood samples collected from the rats into serum separator tubes were centrifuged at 3000 rpm for 15 min. Serum levels of AST, ALT and alkaline phosphatase (ALP) were measured with a Hitachi 7020 automated biochemistry analyzer. The suspensions were centrifuged at 3000 rpm for 15 min. Serum samples were stored at -80°C until analysis.

Histological Analysis Liver were fixed in 10% neutral buffered formalin, embedded in paraffin, cut into 4-µm sections, and stained with hematoxylin and eosin (H&E). Double immunostaining was performed to identify proliferating cell nuclear antigen (PCNA), Ki-67, and F4/80 positive cells. The IHC kit (Cat no.: ab80436) and antibodies (Cat no.: PCNA; ab29, Ki-67; ab15580, F4/80; ab100790) were purchased from Abcam plc. (Cambridge, U.K.).

Assay of HGF, IL-6, and TNF-α in Liver Homogenate Ten milliliters of phosphate buffered saline was added per 1 g of liver tissue cut into 1–2 mm, and the tissues were homogenized. The homogenate was centrifuged at 5000 \times g for 10 min and the supernatant was collected and used for the assay.

Table 1. The Composition of Experimental Group and the Number of Animals Used

| Group       | Treatment     | Animal number of autopsy |
|-------------|---------------|--------------------------|
|             |               | 1 d | 3 d | 5 d | Total |
| Sham control| Vehicle       | 6   | 6   | 6   | 18    |
| PHx + Vehicle| PHx\textsuperscript{a} + vehicle | 6   | 6   | 6   | 18    |
| PHx + 1X Vehicle | hPH\textsuperscript{b} 1.8 mL/kg | 6   | 6   | 6   | 18    |
| PHx + 2X Vehicle | hPH\textsuperscript{b} 3.6 mL/kg | 6   | 6   | 6   | 18    |
| PHx + Losartan | Losartan 5.0 mg/kg | 6   | 6   | 6   | 18    |

\textsuperscript{a) PHx: 2/3 Partial hepatectomy, b) hPH: human placenta hydrolysate.}

RESULTS

Antioxidant Capacity of Human Placenta Hydrolysate It was confirmed that hPH promoted the scavenging activity of DPPH radical (Fig. 1A) and inhibited MDA induced by FeCl\textsubscript{3} in the brain homogenate (Fig. 1B) in a dose-dependent manner.

Effect of Human Placenta Hydrolysate on Hepatocyte Proliferation To confirm the hepatocyte proliferation effect of hPH, serially diluted hPH was treated with HepG2 and hepatocytes. hPH showed significant HepG2 cell proliferation effect at 24 h (Fig. 2A) and 48 h (Fig. 2B) after treatment. Especially, in the 3-fold diluted hPH-treated group, the cell proliferation rate was increased by 21% after 24 h of treatment compared with the untreated group, indicating the highest cell growth promotion effect. In addition, hPH showed significant hepatocyte proliferation effect at 24 h after treatment. In hepatocytes, the highest proliferation rate was observed in the...
36-fold diluted hPH sample (Fig. 2C). The changes in IL-6 levels in human primary hepatocytes treated with hPH were investigated by concentration- and time-dependent methods. Changes in IL-6 expression were investigated according to changes in hPH concentration and also based on time, 4 and 24h. The 36-fold diluted hPH was used as a representative concentration, and IL-6 concentration was investigated at 1, 2, 4, 8, 12, and 24h after hPH treatment. It was found that the concentration of IL-6 began to increase considerably from 4h after hPH treatment and continued to rise until 8h (Fig. 2D). STAT3 and ERK, known to regulate the expression of regeneration genes, are regulated by IL-6 and HGF. The activity of these signaling molecules was enhanced by hPH treatment (Figs. 2E–G). IL-6 and hPH were co-treated with LMT-28, an antagonist of IL-6, to determine whether the cell proliferation effect of hPH was due to IL-6. In human primary hepatocytes, IL-6 demonstrated the maximum growth promotion effect at 25ng/mL compared with Con (Fig. 2H). Up to 19% cell growth promotion was observed at 36-fold diluted hPH when human primary hepatocytes were treated with various concentrations of hPH, and the cell growth promotion effect of hPH was completely inhibited by LMT-28 (Fig. 2I).

**Effect of Human Placenta Hydrolysate on Liver Regeneration in Rats after Partial Hepatectomy**  To confirm the liver regeneration effect of hPH, two doses of hPH (1x or 2x, subcutaneously (s.c.) and losartan (5mg/kg, per os (p.o.)) , an angiotensin II receptor antagonist used as a positive drug, were administered to SD rats after PHx. Regeneration rate was assessed by measuring liver weights at days 1, 3, and 5 after PHx. In the hepatectomized rat, the regeneration ratio was significantly higher in the 2x hPH treatment groups than in the vehicle treatment group at days 1 and 3. On day 5, there was no significant difference among the treated groups. In the sham group, the regeneration ratio did not change with time (Fig. 3A). The levels of HGF, IL-6, and TNF-α were significantly higher in the 2x hPH treatment groups than in the vehicle treatment group at day 1. Levels of TNF-α and IL-6 were significantly higher in the hPH treatment group than in the vehicle treatment group at day 3. The levels of all the factors were significantly higher in the losartan treatment group than in the vehicle treatment group at day 1 but decreased rapidly after this day (Figs. 3B–D). To evaluate the effect of hPH on the activation of Kupffer cells in the partial hepatectomized rats, F4/80 was assessed by IHC staining. The
The number of F4/80-positive cells increased on day 1 after PHx in the hPH treatment groups but not in the losartan treatment groups, and the peak value was significantly higher in the 2x hPH treatment group than in the vehicle treatment group (Figs. 3E, F).

**Histological Change by Human Placenta Hydrolysate in Rats after Partial Hepatectomy** For the double nuclear cell ratio, the ratio in the 2x hPH treatment group was significantly increased at days 1, 3, and 5 compared with that in the vehicle treatment group. For the mitosis cell ratio, the ratio in the 2x hPH treatment group was significantly increased compared with that in the vehicle treatment group at days 3 and 5. In the losartan group, the ratio significantly increased at day 1 or/and 3 but decreased rapidly after these days (Figs. 4A–E, P, Q, 1- and 5-d photographs not shown). The ratio of PCNA-positive cells increased to a peak of 64.2% at day 3 after PHx in all hPH and losartan treatment groups, and the peak value was significantly higher in the 2x hPH treatment group than in the vehicle treatment group (Figs. 4F–J, R, 1- and 5-d). Similarly, the number of Ki-67-positive cells was also significantly higher in the 2x hPH treatment group than in the vehicle treatment group at day 5, and the number in the losartan group was significantly higher than that in the vehicle treatment group at day 1, but decreased rapidly after this day (Figs. 4K–O, S, 1- and 5-d). Moreover, it was confirmed that hPH significantly reduced serum AST, ALT, and ALP levels in the 2x hPH treatment group compared with the vehicle treatment group (Figs. 4T–V).

**Antioxidant Effect of Human Placenta Hydrolysate in Rats after Partial Hepatectomy** To evaluate the effect of hPH on the antioxidant effect in the partial hepatectomized rats, thiobarbituric acid reactive substances (TBARS), glutathione (GSH), superoxide dismutase (SOD), and glutathione peroxidase (GPx) were analyzed using commercial assay kits. TBARS, as a marker of oxidative damage, showed a significant decrease in the hPH-treated group compared with that in the vehicle group (Fig. 5A). GSH, as a source of antioxidant enzymes, showed a significant increase in the hPH-treated group compared with that in the vehicle treatment group (Fig. 5B). Analysis of the activity of SOD and GPx, which are representative antioxidant enzymes, confirmed that the oxidative stress induced by partial hepatectomy was fully recovered by hPH administration (Figs. 5C, D).
DISCUSSION

The liver has a remarkable ability to regenerate after PHx, acute and chronic liver injury, or ischemic damage. Indeed, the normal liver in rat is restored within about a week after PHx. During the rapid regeneration process, massive oxidative stress can occur, which can slow down the regeneration process,\(^2\) and thus, proper removal of oxidative stress may facilitate liver regeneration.

Several bioactive molecules in hPH have been spotlighted in Western and Oriental medicine.\(^2\) There are abundant biologically important factors in hPH, and some of these cytokines and growth factors are known to be essential for liver regeneration.\(^2\)–\(^3\) In primary hepatic cells, we confirmed that IL-6 was induced by treatment with hPH. It was also confirmed that LMT-28, an IL-6 antagonist, inhibited the cell growth promoting effect in HepG2 cells. IL-6 is an important priming factor, which promotes G0 to G1 transition of hepatocytes and allows effective response to growth factors.\(^2\) Moreover, it activates approximately 40% of the early genes involved in liver regeneration, including STAT3 and ERK.\(^2\) It is known that STAT3 promotes cell-cycle progression and cell proliferation under physiological growth conditions.\(^2\)

Furthermore, ERK induces cell proliferation and cyclin D1 expression,\(^3\)–\(^7\) which is an important checkpoint protein in hepatic cell growth. Indeed, in this study, it was confirmed that STAT3 and ERK were activated by treatment of hPH in primary hepatic cells. In primary hepatic cells, treatment with high concentrations of hPH (\(>35\)) leads to hepatic toxicity. However, serum levels of ALT, AST, and ALP were significantly reduced in the 2x hPH treatment group compared with the levels in the vehicle treatment group, consistent with the previous reports.\(^3\) Therefore, the cytotoxicity observed in the in vitro results does not undermine the safety in vivo.

Cell division is rarely observed in normal hepatocytes, as most hepatic cells are in the G0 phase of the cell cycle.\(^2\) However, in the case of large damage such as partial hepatectomy, most hepatocytes rapidly re-enter the cell cycle. In the case of rats, the DNA synthesis is increased by entering the S phase in the cell cycle from 12 h, and peak at about 24 h.\(^2\) Thereafter, mitosis occurs and double nuclear cells increase, eventually occurs liver regeneration.\(^2\) We investigated whether hPH administration could promote liver regeneration after PHx in vivo. The concentrations of IL-6, TNF-\(\alpha\), and
HGF were dramatically induced in the 2x hPH treatment group. These results are in agreement with those of previous reports, indicating that the up-regulation of IL-6, TNF-α, and HGF enhances liver regeneration. Activation of Kupffer cells was also confirmed by F4/80-IHC staining. These results are consistent with those of previous studies in which TNF-α and IL-6 were secreted from activated Kupffer cells. In process of cell cycle conversion, HGF, TNF-α and IL-6 have been implicated in regulating liver regeneration. According to the recent studies using a liver-knockout of Met have confirm that the HGF/Met pathway is major route for DNA synthesis after liver damage. Also HGF is inducer of DNA synthesis in vitro. IL-6 is a major component in hepatic physiology, including hepatoprotection, acute-phase response and mitogenesis. In particular, IL-6 plays an important role in liver regeneration with STAT3. The absence of TNF-α does not damage liver, however TNF-α is also required for a cell proliferation after partial hepatectomy in TNF-receptor-1 knockout mice. Because TNF-α induces the production of IL-6 via up-regulation of nuclear factor-kappaB (NF-κB). Furthermore, we showed that cell mitosis and double nuclei ratio, which are markers of cell proliferation, were increased in the 2x hPH treatment group. Regeneration of normal cells occurs through the differentiation of precursor cells. However, in the liver, cell proliferation occurs by self-renewal of already mature cells. Therefore, mitosis and double nuclear cells can be observed in the liver being regenerated. We confirmed that the percentage of PCNA and KI-67 positive hepatocytes, which are markers of DNA replication and proliferation activity, respectively, were significantly enhanced in 2x hPH-treated livers 3 d after PHx. These results suggest that several cytokines and bioactive molecules contained in hPH triggered repair mechanisms via various signal pathways. It has been found that lipid peroxidation occurs in the early phase of liver regeneration and that diminished lipid peroxidation contributes to cell proliferation after PHx. In addition, it has been reported that a damaged oxidative stress defense system inhibits liver regeneration. The crucial players for defending against oxidative stress include detoxifying electrophiles and radicals and antioxidant proteins and enzymes, such as SOD, GPx, and GSH. Superoxide anion is dismutated by SOD to hydrogen peroxide, which is detoxified to water by GPx. Importantly, GPx requires an adequate amount of GSH to detoxify H2O2; therefore, depletion of GSH below normal levels can lead to, or favor, mitochondrial dysfunction and cell death. This study has shown that the levels of TBARS were significantly increased in the liver at days 1, 3, and 5 after PHx. In addition, PHx also damaged antioxidant systems such as SOD, GPx, and GSH. These damages were mostly prevented by 1x or 2x hPH treatments.
It has been reported that the major anti-oxidant components in human placenta extract are uracil, tyrosine, phenylalanine, and tryptophan. Approximately 59% of the antioxidative effects of human placenta extract can be explained by the actions of these components. In previous studies that used the same hPH, it was confirmed that hPH contains various amino acids, including arginine (0.08%), lysine (0.1%), phenylalanine (0.08%), tyrosine (0.03%), leucine (0.12%), methionine (0.03%), valine (0.04%), alanine (0.08%), serine (0.07%), and threonine (0.06%). Therefore, it can be assumed that these amino acids have a role in removing oxidative stress and increasing antioxidant enzymes.

According to the previous study, nuclear factor-E2-related factor 2 (Nrf2) pathway-related gene expression in HepG2 cells was activated by hPH treatment. The activation of Nrf2 upregulates antioxidant enzymes, including SOD and GPx, reducing ROS. In many studies, Nrf2 was upregulated by arginine, alanine, lysine, phenylalanine and tyrosine as a major amino acid contained in hPH. According to previously study, The Nrf2 signaling pathway is negatively regulated by Keap1. There is a directly interacted between p62 and Keap1 and that the amino acids and the three arginine residues such as positions 380, 415, and 483 in Keap1 are essential for the interaction between these proteins. Thus, Nrf2 seems to be one of major pathway for the antioxidiant effect of amino acids. In addition, previous studies have shown that amino acids stimulate DNA synthesis in the normal liver of protein-deprived animals. It has been shown that the infusion of amino acids increases the activity of certain enzymes involved in the synthesis of pyrimidine nucleotides and DNA during liver regeneration process. Leucine, threonine, and valine, found to be contained in hPH, are more essential than other amino acids in inducing new DNA synthesis in protein-deficient animals. In contrast to these results, some studies have shown that elimination of lipid peroxidation inhibits liver regeneration. These results suggest that lipid peroxidation may paradoxically play a role in the cell proliferation cascade. Potent antioxidants such as vitamin E could induce early termination of cell proliferation event to suppress liver regeneration. Although many studies aiming at efficacy have reported positive results for antioxidant effects, a more careful interpretation is needed because anti-oxidative effects are bi-faceted in the tissue regeneration process.

In this study, we confirmed that hPH contains diverse growth factors and cytokines that are associated with liver regeneration and demonstrate efficacy in liver regeneration. Therefore, we suggest that hPH can trigger liver regeneration via cytokine- and growth factor-mediated signaling pathways. It was also suggested that hPH can eliminate oxidative stress during liver regeneration. Nevertheless, hPH has not yet been fully studied because it is known to contain various components other than cytokines, growth factors, and amino acids. This implies that a study of the undefined physiological activity of hPH is required. Taken together, hPH may be a good alternative for the treatment of liver injury and for the regeneration of the liver after living donor liver transplantation.
