high-risk for HIV. Although this program is sustainable, efforts to improve steps along the PrEP care continuum are still needed in this population.

1296. Potential use of Sexually Transmitted Infection (STI) Testing for Expanding HIV Pre-Exposure Prophylaxis (PrEP) at an Urban Hospital Center

Robert Pitts, MD; Robert Holzman, MD, FIDSA, FSHEA; Richard Greene, MD; Emily Lam, BS; Ellie Carmody, MD, MPH and Scott Breathwaite, MD; Infectious Diseases, New York University, New York, New York; NYU Medical Center, New York, New York; Medicine, New York University, New York, New York; Division of Infectious Diseases and Immunology, New York University School of Medicine, New York, New York; Department of Population Health, New York University, New York, New York

Session: 142. HIV: Prevention
Friday, October 5, 2018: 12:30 PM

Background. Despite the high efficacy of PrEP, it continues to be underutilized. We examined the extent to which patients with a documented positive test for STIs were provided PrEP at an urban municipal medical center.

Methods. We reviewed data of all patients seen between January 1, 2014 and July 30, 2017 who were > 18 years old and had an initial HIV negative test and ≥1 positive test for Chlamydia, Gonorrhea, or Syphilis. We examined PrEP prescription data by gender, race/ethnicity, and clinic location. Differences between groups were compared using Chi-squared analysis and logistic regression.

Results. Of 1,142 initially HIV− patients who were identified as having a positive STI result, 52% were female, 89% either Black or Hispanic, with a median age of 40 years (quarters 30, 47). 58% had Medicare/Medicaid and 34% were self-pay or uninsured (Table 1). Only 25 (2.1%) of 1,142 patients who had ≥1 STI test positive were prescribed PrEP. No women received PrEP. Whites (aOR: 21.7 [95% CI: 4.4, 107, P = 0.001] and Hispanics (aOR: 6.64 [95% CI: 1.35, 32.8, P = 0.029]) were both more likely to receive PrEP than Blacks, after adjusting for age, sex, marital status, and insurance. All PrEP prescriptions originated from the Medicine, Emergency, or HIV specialty clinics although most STI testing was obtained in Emergency and Obstetrical/Gynecological clinics (Table 2).

Conclusion. There were significant missed opportunities for HIV prevention among patients with STIs within the medical center, particularly among Hispanic and Black patients. Enrichment programs to educate providers and increase PrEP prescription may have a major impact on expanding HIV prevention, especially for women.

Friday, October 5, 2018: 12:30 PM

Session: 142. HIV: Prevention

Background. Pre-exposure prophylaxis (PrEP) with emtricitabine/tenofovir (TFV) disoproxil fumarate (FTC/TFV) is highly protective against HIV infection. We report the second case of acquisition of TDF-susceptible HIV despite high adherence to PrEP confirmed by drug level testing.

Methods. PrEP adherence was assessed by measuring FTC/TFV metabolites in dried blood spots (DBS) and FTC/TFV concentrations in segments of scalp hair. Genotypic and phenotypic resistance were evaluated. HIV partner services (PS) and HIV sequences reported the HIV surveillance with a genetic distance ≤1.5% by (HIV-Trace) identified likely transmission partners.

Results. A 21-year-old Latino man presented 13 months after PrEP initiation. He was HIV negative by rapid HIV antibody (Ab) and HIV RNA polymerase chain reaction (PCR) at 3, 6, and 10. At PrEP initiation visit, he was asymptomatic and his rapid HIV Ab was negative. Five days later, his HIV RNA was reported as positive (559 copies/mL). He was notified of the result, linked to care and immediately started antiretroviral treatment (ART), at which point his RNA was 1544 copies/mL and his HIV Ab test was positive. The HIV genotype had M184V, L74V and K103N mutations and phenotypic susceptibility to TDF. TDF/FTC levels by LC-MS/MS measured in 1 cm segments of hair collected at ART initiation indicated consistently high PrEP adherence in each of the preceding 6 months. TFV-diphosphate and FTC-triphosphate levels in DBS collected 2 days after ART initiation were 1012 fmol/punch and 0.266 pmol/punch, confirming high adherence over the preceding 6 weeks. Between PrEP initiation and HIV acquisition, he had 1 episode of urinary chlamydia and three episodes of urethral gonorrhea. The likely transmission partner, named during PrEP, had no history of viral suppression in HIV surveillance and harbored the same resistance mutations, with a genetic distance between the two patients of 0.66%.

Conclusion. Acquisition of TDF-susceptible HIV infection can occur despite high PrEP adherence. Quarterly HIV and STD screening of patients on PrEP, combined with prompt linkage to care and PrEP for those diagnosed with HIV, facilitates early diagnosis and prevents further transmission of HIV.

Session: 142. HIV: Prevention

Friday, October 5, 2018: 12:30 PM

Background. Access to HIV pre-exposure prophylaxis (PrEP) is often poor in small urban and rural areas due to long distances to PrEP providers and stigma. In 2017, the Iowa Department of Public Health (IDPH), University of Iowa, and community representatives collaborated to develop a public health-partnered telemedical PrEP delivery model to overcome these barriers (TelePrEP). IDPH personnel working in five sexually transmitted infection (STI) clinics and partner services (PS) programs in Eastern Iowa interviewed clients for PrEP indications and referrals who need to TelePrEP pharmacist providers at UI. Via collaborative practice, pharmacists completed initial and follow-up PrEP home video visits with clients on smart phones and laptops. Clients obtained laboratory monitoring and STI screening in public health-affiliated and local laboratories in accordance with USPSPS/CDC guidelines, and received PrEP medication by mail. PS personnel linked TelePrEP clients with newly-identified STIs to local treatment.

Methods. Using the PrEP continuum as framework, we used IDPH databases and UI medical records to conduct a retrospective process evaluation of the TelePrEP model (February 2017–April 2018),

Results. TelePrEP received 44 referrals from public health and 59 self-referrals via advertising. Pramacists completed 84 initial visits (81% of referrals), including 37 visits (84%) with clients referred by public health. Most (94%) started emtricitabine/tenofovir after initial visits. Retention in TelePrEP at 6 months was 87%. 96% of participants (15/16 positive HIV, 48TDF/FTC, 9TDF/FTC) were completed at baseline and follow up. Rates of extragenital chlamydia and gonorrhea screening were lower (74 of 104 completed screens) due to variable availability of swabs at local laboratories. 15 clients were diagnosed with 20 STIs on screening (6 syphilis, four gonorrhea, 10 chlamydia). One undiagnosed TDF- and one undiagnosed HIV-Signaled pregnancy was identified. PS linked all clients with STIs on screens to treatment within 14 days (80% in 3 days).

Conclusion. Using telemedicine, healthcare systems can partner with public health administered STI clinics and PrEP programs to create virtual PrEP delivery models in rural settings. Public health partnerships enhance client identification and ensure linkage to care for new STI diagnoses in telemedicine programs.

1300. Young Heterosexual Men in Rural South Africa Want Access to PrEP

Alisse Hannaford, BS3,4; Bulelani Khosa, NSC5; Anthony P Moll, MBBCh8 and Sheila V Shoeni, MD, MPH1; 1Icahn School of Medicine at Mount Sinai, New York City, New York, 2Yale University School of Medicine, New Haven, Connecticut, 3Doris Duke Charitable Foundation, New Haven, Connecticut, 4Church of Scotland Hospital, Tugela Ferry, KwaZulu-Natal, South Africa

Session: 142. HIV: Prevention

Friday, October 5, 2018: 12:30 PM

Background. While many HIV prevention services in South Africa specifically support women and girls, substantial gaps exist in HIV prevention, testing and treatment services targeting men and boys. We aimed to characterize HIV prevention knowledge, sexual-risk behaviors and interest in HIV pre-exposure prophylaxis (PrEP) among young men in rural KwaZulu-Natal.

Methods. Men were identified at community settings such as taverns, fast-food restaurants, and local stores. Interviews were conducted confidentially and anonymously in Zulu, and were recorded, translated and transcribed. Transcripts were coded to identify themes.

Results. Thirty-one HIV negative men (median age 26, IQR 23–31) were interviewed, 52% with a history of STI and 77% unemployed. While most (61%) perceived themselves to be at risk for HIV, less than half had tested for HIV in the prior 3 months (36%), the majority reported inconsistent condom use (87%), and most reported partners outside their relationship (84%). While only a quarter had previously heard of PrEP, all were interested in initiating, four participants felt PrEP should only be for men because polygamy is acceptable. While most men wanted their partners on PrEP (77%), they also felt that their female partners initiating PrEP would signify a lack of trust in the relationship, while paradoxically acknowledging that their own multiple sexual relationships put their partner at risk. Men expressed the destigmatizing of new relationships by asking about HIV status, and admitted being less likely to discuss HIV status and condoms during sexual encounters involving alcohol. Men felt that using PrEP might lead to decreased condom use and enable their female partners to be sexually active with other men. Men were concerned that if they initiated PrEP they would be mistaken as HIV positive.

Conclusion. Men in heterosexual relationships in rural South Africa acknowledge engaging in high HIV risk behaviors and feel that they should have access to PrEP. They report contradictory perspectives about their female partners accessing PrEP and are concerned about PrEP increasing HIV risk behaviors, which needs further exploration. Heterosexual men in sub-Saharan Africa should be targeted for combination HIV prevention services, including PrEP.

1301. Evaluation of the Rates of HIV Post-Exposure Prophylaxis Completion After the Implementation of an Automated Referral System in the Emergency Department

Elizabeth K. Nagy, MD, MSc; Katsugi Schwarz, MD3; Madeleine Gyis, MD3; Finn Schubert, MPH4 and Fanny Ita-Nagy, MD5; 1Internal Medicine, NYU Langone Hospital-Brooklyn, Brooklyn, New York, 2Clinical Research, NYU Langone Hospital-Brooklyn, Brooklyn, New York, 3Infectious Diseases and Immunology, NYU Langone Hospital-Brooklyn, Brooklyn, New York

Session: 142. HIV: Prevention

Friday, October 5, 2018: 12:30 PM

Background. A 28-day regimen of Post-Exposure Prophylaxis (PEP) administered within 72 hours significantly reduces HIV infection, for both occupational and nonoccupational exposures (NOE); however, adherence to PEP for NOE has been reported to have poor rates of completion. To optimize PEP referrals from our ED to our clinics, we implemented an automated referral system to maximize PEP completion and link patients to outpatient care and HIV pre-exposure prophylaxis (PrEP), if eligible.
