ANALYSIS OF THE MASSES AND DECAY CONSTANTS OF THE HEAVY-LIGHT MESONS WITH QCD SUM RULES

Zhi-Gang Wang

Department of Physics, North China Electric Power University, Baoding 071003, P. R. China

Abstract

In this article, we calculate the contributions of the vacuum condensates up to dimension-6 including the $O(\alpha_s)$ corrections to the quark condensates in the operator product expansion, then study the masses and decay constants of the pseudoscalar, scalar, vector and axial-vector heavy-light mesons with the QCD sum rules in a systematic way. The masses of the observed mesons ($D, D^*$), ($D_s, D_s^*$), ($D_s^0(2400), D_s(2430)$), ($D_s^{*0}(2317), D_s(2460)$), ($B, B^*$), ($B_s, B_s^*$) can be well reproduced, while the predictions for the masses of the ($B_s^0, B_1$) and ($B_s^0, B_{s1}$) can be confronted with the experimental data in the future. We obtain the decay constants of the pseudoscalar, scalar, vector and axial-vector heavy-light mesons, which have many phenomenological applications in studying the semi-leptonic and leptonic decays of the heavy-light mesons.

1 Introduction

The charged heavy-light mesons can decay to a charged lepton pair $\ell^+\nu_\ell$ through a virtual $W^+$ boson. Those leptonic decays are excellent subjects in studying the CKM matrix elements and serve as a powerful probe of new physics beyond the standard model in a complementary way to the direct searches. For example, the decay widths of the pseudoscalar (P) and vector (V) heavy-light mesons can be written as

$$
\Gamma(P \to \ell\nu) = \frac{G_F^2}{8\pi} f_P^2 m_\ell^2 m_P \left(1 - \frac{m_\ell^2}{m_P^2}\right)^2 |V_{q_1q_2}|^2 ,
$$

$$
\Gamma(V \to \ell\nu) = \frac{G_F^2}{12\pi} f_V^2 m_\ell^3 |V_{q_1q_2}|^2 \left(1 + \frac{m_\ell^2}{2m_V^2}\right) |V_{q_1q_2}|^2 ,
$$

in the lowest order approximation, where the $m_{P/V}$ and $f_{P/V}$ are the masses and decay constants, respectively, the $m_\ell$ is the $\ell$ mass, the $V_{q_1q_2}$ is the CKM matrix element between the constituent quarks $q_1q_2$, and the $G_F$ is the Fermi coupling constant. If we take the CKM matrix element $V_{q_1q_2}$ and the branching fractions of the leptonic decays from the CLEO, BaBar, Belle collaborations as input parameters, then the average values $f_D = (204.6 \pm 5.0)$ MeV, $f_{D_s} = (257.5 \pm 4.6)$ MeV and $f_{D_s}/f_D = 1.258 \pm 0.038$ are obtained [1]. It is difficult to reproduce the three values consistently in theoretical calculations, such as the QCD sum rules [2, 3, 4] and lattice QCD [6, 7, 8]. The discrepancies between the theoretical values and experimental data maybe signal some new physics beyond the standard model [9]. In Ref. [10], we observe that if we take into account the $O(\alpha_s^2)$ corrections to the perturbative terms and the $O(\alpha_s)$ corrections to the quark condensate terms and choose the pole masses, the predictions $f_D = (211 \pm 14)$ MeV, $f_{D_s} = (258 \pm 13)$ MeV and $f_{D_s}/f_D = 1.22 \pm 0.08$ are in excellent agreement with the experimental data [1].

In the QCD sum rules for the heavy-light mesons, the Wilson coefficients of the vacuum condensates at the operator product expansion side from different references differ from each other in one way or the other according to the different approximations [2, 3, 10, 11, 12]. In this article, we recalculate the contributions of the vacuum condensates up to dimension-6, including the one-loop corrections to the quark condensates, and take into account the terms neglected in previous works.

---

then study the masses and decay constants of the pseudoscalar, scalar, vector and axial-vector heavy-light mesons in a systematic way.

There have been many theoretical works on the decay constants of the heavy-light mesons, such as the QCD sum rules \cite{2, 3, 4, 5, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21}, the lattice QCD \cite{1, 2, 8, 22, 23, 24, 25, 26, 27}, the Bethe-Salpeter equation \cite{28, 29}, the relativistic potential \cite{30, 31, 32, 33, 34}, the chiral-quark model \cite{35}, the extended chiral-quark model \cite{36}, the constituent quark model \cite{37}, etc.

The article is arranged as follows: we derive the QCD sum rules for the masses and decay constants of the heavy-light mesons in Sect.2; in Sect.3, we present the numerical results and discussions; and Sect.4 is reserved for our conclusions.

## 2 QCD sum rules for the heavy-light mesons

In the following, we write down the two-point correlation functions $\Pi_{0/5}(p)$ and $\Pi_{V/A}^{\mu\nu}(p)$ in the QCD sum rules,

\begin{align}
\Pi_{0/5}(p) &= i \int d^4x e^{ipx} \langle 0 | T \left\{ J_{0/5}(x) J_{0/5}^\dagger(0) \right\} | 0 \rangle, \\
\Pi_{V/A}^{\mu\nu}(p) &= i \int d^4x e^{ipx} \langle 0 | T \left\{ J_{V/A}^\mu(x) J_{V/A}^{\nu\dagger}(0) \right\} | 0 \rangle,
\end{align}

where the currents $J_5(x)$, $J_0(x)$, $J_V^\mu(x)$ and $J_A^\mu(x)$ interpolate the pseudoscalar, scalar, vector and axial-vector heavy-light mesons, respectively, $Q = c, b$ and $q = u, d, s$. We can insert a complete set of intermediate hadronic states with the same quantum numbers as the current operators $J_5(x)$, $J_0(x)$, $J_V^\mu(x)$ and $J_A^\mu(x)$ into the correlation functions $\Pi_{0/5}(p)$ and $\Pi_{V/A}^{\mu\nu}(p)$ to obtain the hadronic representation \cite{38, 39}. After isolating the ground state contributions from the pseudoscalar, scalar, vector and axial-vector heavy-light mesons, we get the following results,

\begin{align}
\Pi_0(p) &= \frac{f_S^2 m_S^2}{m_S^2 - p^2} + \cdots, \\
\Pi_5(p) &= \frac{f_P^2 m_P^4}{(m_Q + m_q)^2 (m_P^2 - p^2)} + \cdots, \\
\Pi_{V/A}^{\mu\nu}(p) &= \frac{f_{V/A}^2 m_{V/A}^2}{m_{V/A}^2 - p^2} \left( -g_{\mu\nu} + \frac{p^{\mu} p^{\nu}}{p^2} \right) + \cdots
\end{align}

where the decay constants $f_{S/P/V/A}$ are defined by

\begin{align}
\langle 0 | J_0(0) | S(p) \rangle &= f_S m_S, \\
\langle 0 | J_5(0) | P(p) \rangle &= f_P m_P^2 \frac{1}{m_Q + m_q}, \\
\langle 0 | J_{V/A}^{\mu}(0) | V/A(p) \rangle &= f_{V/A} m_{V/A} \epsilon^\mu,
\end{align}

the $\epsilon^\mu$ are the polarization vectors of the vector and axial-vector mesons.
Now we carry out the operator product expansion at large space-like region $P^2 = -p^2$. The analytical expressions of the perturbative $O(\alpha_s)$ corrections to the perturbative terms for all the correlation functions \cite{17,18} and the semi-analytical expressions of the perturbative $O(\alpha_s^2)$ corrections to the perturbative terms for the pseudoscalar current’s correlation functions \cite{19} are available now. We take into account those analytical and semi-analytical expressions directly \cite{17,18,19}; and recalculate the contributions of the vacuum condensates, i.e. we calculate the Feynman diagrams shown in Figs.1-5, where the solid and dashed lines denote the light and heavy quark lines, respectively, the wave line denotes the gluon line. In calculating the diagrams in Fig.2, we correct the minor errors in Ref.\cite{10}, where the quark condensate $\langle \bar{q}q \rangle_{12}$ in the full light-quark propagators is replaced with $\langle \bar{q}q \rangle_{3D}$, the $D$ is the dimension of the space-time. A minor error occurs when there exist divergences, such a step should be deleted, i.e. the quark condensate $\langle \bar{q}q \rangle_{12}$ survives in the $D$-dimension. In Ref.\cite{40}, we correct the minor errors and improve the calculations, and obtain the correct expressions. Furthermore, we obtain the perturbative $O(\alpha_s)$ corrections to the quark condensate terms for the vector and axial-vector currents.

Figure 1: The diagram contributes to the quark condensate $\langle \bar{q}q \rangle$.

Figure 2: The perturbative $O(\alpha_s)$ corrections to the quark condensate $\langle \bar{q}q \rangle$.

Figure 3: The diagrams contribute to the mixed condensate $\langle \bar{q}g_\sigma Gq \rangle$. 
Figure 4: The diagrams contribute to the gluon condensate $\langle \frac{\alpha_s G G}{\pi} \rangle$ and three-gluon condensate $\langle g_3^2 G G G \rangle$.

Figure 5: The diagrams contribute to the four-quark condensate $\langle \bar{q} q \rangle^2$. 
Once analytical expressions of the QCD spectral densities are obtained, then we can take the quark-hadron duality below the continuum thresholds and perform the Borel transforms with respect to the variable $P^2 = -p^2$ to obtain the QCD sum rules,

$$\frac{f_B^2 m^4_B}{(m_Q + m_q)^2} \exp\left(-\frac{m_B^2}{T^2}\right) = B_T \Pi_5, \quad (9)$$

$$f_S^2 m_S^2 \exp\left(-\frac{m_S^2}{T^2}\right) = B_T \Pi_0, \quad (10)$$

$$f_V^2 m_V^2 \exp\left(-\frac{m_V^2}{T^2}\right) = B_T \Pi_V, \quad (11)$$

$$f_A^2 m_A^2 \exp\left(-\frac{m_A^2}{T^2}\right) = B_T \Pi_A, \quad (12)$$

where

$$B_T \Pi_5 = B_T \Pi_5^0 + B_T \Pi_5^3 + B_T \Pi_5^4 + B_T \Pi_5^5 + B_T \Pi_5^6,$$

$$B_T \Pi_0 = B_T \Pi_5 |_{m_Q = -m_Q}, \quad (13)$$

$$B_T \Pi_V = B_T \Pi_V^0 + B_T \Pi_V^3 + B_T \Pi_V^4 + B_T \Pi_V^5 + B_T \Pi_V^6,$$

$$B_T \Pi_A = B_T \Pi_V |_{m_Q = -m_Q}, \quad (14)$$

$$B_T \Pi_5^0 = \frac{3}{8 \pi^2} \int_{m_Q^2}^{s_0} ds \left(1 - \frac{m_Q^2}{s}\right)^2 \left\{1 + \frac{2m_q m_Q}{s - m_Q^2} + \frac{4\alpha_s}{3 \pi} R_5 \left(\frac{m_Q^2}{s}\right)\right\} \exp\left(-\frac{s}{T^2}\right), \quad (15)$$

$$B_T \Pi_5^3 = -m_Q \langle \bar{q}q \rangle \left\{1 + \frac{\alpha_s}{\pi} \left[6 - \frac{4m_Q^2}{3T^2} - \frac{2}{3} \left(1 - \frac{m_Q^2}{T^2}\right) \log \frac{m_Q^2}{\mu^2} - 2 \Gamma \left(0, \frac{m_Q^2}{T^2}\right) \right]\right\} \exp\left(-\frac{m_Q^2}{T^2}\right) + \frac{m_q \langle \bar{q}q \rangle}{2} \left(1 + \frac{m_q^2}{T^2}\right) \exp\left(-\frac{m_Q^2}{T^2}\right), \quad (16)$$

$$B_T \Pi_5^4 = \frac{1}{12} \langle G G G \rangle \exp\left(-\frac{m_Q^2}{T^2}\right), \quad (17)$$

$$B_T \Pi_5^5 = -\left\{\frac{m_Q \langle \bar{q}g_s \sigma Gq \rangle}{2T^2} \left(1 - \frac{m_Q^2}{2T^2}\right) + \frac{m_q m_Q^4}{12T^6} \langle \bar{q}g_s \sigma Gq \rangle\right\} \exp\left(-\frac{m_Q^2}{T^2}\right), \quad (18)$$

$$B_T \Pi_5^6 = \frac{16 \pi \alpha_s \langle \bar{q}q \rangle^2}{27 T^2} \left(1 + \frac{m_Q^2}{2T^2} - \frac{m_q^4}{12T^4}\right) \exp\left(-\frac{m_Q^2}{T^2}\right) + \frac{\langle G G G \rangle}{\pi^2}\left\{\frac{5}{192T^2} + \frac{1}{768 m_Q^2} + \frac{5m_Q^2}{1536T^4} - \frac{m_Q^4}{768 T^6} - \left(\frac{m_Q^2}{128 T^4} + \frac{m_Q^4}{384 T^6}\right) \log \frac{m_Q^2}{T^4}\right\} \exp\left(-\frac{m_Q^2}{T^2}\right), \quad (19)$$
\[ B_T \Pi_V^0 = \frac{1}{8\pi^2} \int_{m_s^2}^{s_0} dss \left( 1 - \frac{m_Q^2}{s} \right)^2 \left( 2 + \frac{m_Q^2}{s} \right) \left\{ 1 + \frac{6s m_q m_Q}{(s - m_Q^2)(2s + m_Q^2)} + \frac{4\alpha_s}{3\pi} R_V \left( \frac{m_Q^2}{s} \right) \right\} \exp \left( -\frac{s}{T^2} \right), \]  

\[ B_T \Pi_V^3 = -m_Q \langle \bar{q}q \rangle \left\{ 1 + \frac{\alpha_s}{\pi} \left[ \frac{8}{3} - \frac{4m_Q^2}{3T^2} + \frac{2}{3} \left( 2 + \frac{m_Q^2}{T^2} \right) \right] \log \frac{m_Q^2}{\mu^2} - \frac{2m_Q^2}{3T^2} \Gamma \left( 0, \frac{m_Q^2}{T^2} \right) \exp \left( \frac{m_Q^2}{T^2} \right) \right\} \exp \left( -\frac{m_Q^2}{T^2} \right), \]  

\[ B_T \Pi_V^4 = -\frac{1}{12} \left( \frac{\alpha_s GG}{\pi} \right) \exp \left( -\frac{m_Q^2}{T^2} \right), \]  

\[ B_T \Pi_V^5 = \frac{m_Q^2 \langle \bar{q}g_s G G q \rangle}{4T^4} + \frac{m_Q \langle \bar{q}g_s G G q \rangle}{12T^2} \left( 1 + \frac{m_Q^2}{T^2} - \frac{m_Q^2}{T^4} \right) \exp \left( -\frac{m_Q^2}{T^2} \right) \]  

\[ + \frac{20\alpha_s \langle \bar{q}q \rangle}{81T^2} \left( 1 + \frac{m_Q^2}{T^2} - \frac{m_Q^2}{T^4} \right) \exp \left( -\frac{m_Q^2}{T^2} \right) + \frac{\langle g_s^2 G G \rangle}{\pi^2} \left\{ -\frac{1}{1152T^2} + \frac{1}{1152m_Q^2} \right. \]  

\[ + \frac{m_Q^2}{768T^4} \left( 1 - \frac{m_Q^2}{T^2} \right) + \frac{55m_Q^2}{4608T^4} + \frac{1}{192T^2} \left( 1 + \frac{m_Q^2}{T^2} - \frac{m_Q^2}{T^4} \right) \log \frac{m_Q^2}{\mu^2} \exp \left( -\frac{m_Q^2}{T^2} \right) \right\}, \]  

\[ R_5(x) = \frac{9}{4} + 2L_{i2}(x) + \log x \log(1 - x) - \frac{3}{2} \log \frac{1 - x}{x} - \log(1 - x) + x \log \frac{1 - x}{x} - \frac{x}{1 - x} \log x, \]  

\[ R_V(x) = \frac{13}{4} + 2L_{i2}(x) + \log x \log(1 - x) - \frac{3}{2} \log \frac{1 - x}{x} - \log(1 - x) + x \log \frac{1 - x}{x} - \frac{x}{1 - x} \log x \]  

\[ + \frac{(3 + x)(1 - x)}{2 + x} \log \frac{1 - x}{x} - \frac{2x}{(2 + x)(1 - x)^2} \log x - \frac{5 + 2x}{2 + x} - \frac{2x}{(2 + x)(1 - x)}, \]  

\[ \Gamma(0, x) = e^{-x} \int_0^\infty dt \frac{1}{t + x} e^{-t}, \]  

\[ L_{i2}(x) = -\int_0^x dt \frac{1}{t} \log(1 - t), \]  

and the \( s_i \) are the continuum threshold parameters. The perturbative \( O(\alpha_s) \) corrections \( R_5(x) \) and \( R_V(x) \) are taken from Refs.\[17,18\]. We can also take into account the semi-analytical perturbative \( O(\alpha_s^2) \) corrections to the perturbative terms for the \( B_T \Pi_V^0 \).

\[ \frac{1}{8\pi^2} \left( \frac{\alpha_s}{\pi} \right)^2 \int_{m_s^2}^{s_0} ds \left\{ \frac{16}{9} R_{2sFF}[v] + 4 R_{2sFA}[v] + \frac{2m}{3} R_{2sFL}[v] + \frac{2}{3} R_{2sFH}[v] \right\} \exp \left( -\frac{s}{T^2} \right), \]  

where the \( R_{2sFF}[v], R_{2sFA}[v], R_{2sFL}[v] \) and \( R_{2sFH}[v] \) with the variable \( v = \left( 1 - \frac{m_s^2}{s} \right) / \left( 1 + \frac{m_s^2}{s} \right) \) are mathematical functions defined at the energy-scale of the pole mass \( \mu = m_c \), here the \( n_i \) counts the number of massless quarks \[19\].

We can derive Eqs.\(9-12\) with respect to \( 1/T^2 \), then eliminate the decay constants \( f_{S/P/V/A} \) to obtain the QCD sum rules for the masses.

\[ m_{S/P/V/A}^2 = \frac{d}{d \ln T^2} \frac{B_T \Pi_0/5/V/A}{B_T \Pi_0/5/V/A}. \]
Once the masses $m_{S(P)\ell\ell}$ are obtained, we can take them as input parameters and obtain the decay constants from the QCD sum rules in Eqs.(9-12).

In the case of the light-quark currents, the perturbative $O(\alpha_s)$ corrections to the perturbative terms amount to multiplying the factors $1 + \frac{1}{3} \alpha_s \approx 1 + 3.67 \frac{\alpha_s}{\pi}$ and $1 + \frac{\alpha_s}{3\pi}$ to the perturbative terms in the correlation functions for the pseudoscalar (scalar) and vector (axial-vector) currents, respectively [39]. In the present case, if we take the approximation $\mu^2 = m^2_{\ell} + T^2$, the perturbative $O(\alpha_s)$ corrections to the quark condensate terms amount to multiplying the factors $1 + 3.47 \frac{\alpha_s}{\pi}$ and $1 + 0.94 \frac{\alpha_s}{\pi}$ to the quark condensate terms in the correlation functions for the pseudoscalar (scalar) and vector (axial-vector) currents, respectively. The analogous $O(\alpha_s)$ corrections indicate that the present calculations are reliable.

3 Numerical results and discussions

In the heavy quark limit, the heavy-light mesons $Q\bar{q}$ can be classified in doublets according to the total angular momentum of the light antiquark $\vec{s}_\ell$, $\vec{s}_\ell = \vec{s}_{\bar{q}} + \vec{L}$, where the $\vec{s}_{\bar{q}}$ and $\vec{L}$ are the spin and orbital angular momenta of the light antiquark, respectively. The spin doublets $(D, D^*)$, $(B_s, B_s^*)$, $(D_0(2400), D_1(2430))$, $(D_{s1}(2317), D_{s1}(2460))$, $(B, B^*)$, $(B_s, B_s^*)$ have been observed, the masses are $m_{D^\pm} = (1869.5 \pm 0.4)$ MeV, $m_{D^0} = (1864.84 \pm 0.07)$ MeV, $m_{D^+,(2010)} = (2010.26 \pm 0.07)$ MeV, $m_{D^+,(2007)} = (2006.96 \pm 0.10)$ MeV, $m_{D^0(2400)} = (2318 \pm 29)$ MeV, $m_{D_s(2460)} = (2403 \pm 14 \pm 35)$ MeV, $m_{D_s(2440)} = (2427 \pm 26 \pm 25)$ MeV, $m_{D_s^+} = (1969.0 \pm 1.4)$ MeV, $m_{D_{s1}(2112)} = (2112.1 \pm 0.4)$ MeV, $m_{D_{s1}(2317^*)} = (2318.0 \pm 1.0)$ MeV, $m_{D_{s1}(2460)} = (2459.6 \pm 0.9)$ MeV, $m_{B^+} = (5279.25 \pm 0.26)$ MeV, $m_{B^0} = (5279.55 \pm 0.26)$ MeV, $m_{B_s^+} = (5325.2 \pm 0.4)$ MeV, $m_{B_s^0} = (5366.7 \pm 0.4)$ MeV, $m_{D_{s1}^+} = (5415.8 \pm 1.5)$ MeV from the Particle Data Group [41]. The spin doublets $(B_s^*, B_s)$ and $(B_{s1}^*, B_{s1})$ have not been observed yet. The doublet $(D(2550), D(2600))$ or $(D_f(2580), D_{f1}(2650))$ is tentatively identified as the first radial excited state of the doublet $(D, D^*)$, the doublet $(?, D_s^*(2112))$ is tentatively identified as the first radial excited state of the doublet $(D_s, D_s^*(2112))$ [41].

We take the values $\sqrt{s_0} = m_{q\bar{q}} + (0.4 - 0.8)\text{ GeV}$ as guides, here the $gr$ denotes the ground states, and search for the optimal threshold parameters $s_0$ and Borel parameters $T^2$ to satisfy the following criteria:

- Pole dominance at the phenomenological side;
- Convergence of the operator product expansion;
- Appearance of the Borel platform;
- Reappearance of experimental values of the ground state heavy meson masses.

The contributions of the ground states can be fully taken into account by choosing the threshold parameters $\sqrt{s_0} = m_{q\bar{q}} + (0.4 - 0.8)\text{ GeV}$. The contaminations of the excited states are very small if there are some contaminations, we expect that the couplings of the currents to the excited states are more weak than that to the ground states. For example, the decay constants of the pseudoscalar mesons $\pi(140)$ and $\pi(1800)$ have the hierarchy $f_\pi(1300) \ll f_\pi(140)$ from the lattice QCD [42], the QCD sum rules [43], or from the experimental data [44].

The vacuum condensates are taken to be the standard values $\langle \bar{u}u \rangle = \langle \bar{d}d \rangle = -(0.24 \pm 0.01)\text{ GeV}^3$, $\langle \bar{s}s \rangle = (0.8 \pm 0.1)\langle \bar{u}u \rangle$, $\langle \bar{q}q_s\sigma Gq \rangle = m_0^2\langle \bar{q}q \rangle$, $m_0^2 = (0.8 \pm 0.1)\text{ GeV}^2$, $\langle \frac{\alpha_s\sigma}{\pi} \rangle = (0.33\text{ GeV})^4$, $\langle g_4^2 GGG \rangle = 0.045\text{ GeV}^6$ at the energy scale $\mu = 1\text{ GeV}$ [38] [39]. The quark condensates and mixed quark condensates evolve with the renormalization group equation, $\langle \bar{q}q \rangle(\mu) = \langle \bar{q}q \rangle(Q)\frac{\alpha_s(Q)}{\alpha_s(\mu)}\frac{\alpha_s(\mu)}{\alpha_s(\mu)}\hat{T}$.

In the article, we take the $\overline{MS}$ masses $m_b(m_b) = (4.18 \pm 0.03)\text{ GeV}$, $m_c(m_c) = (1.275 \pm 0.025)\text{ GeV}$ and $m_{\rho}(\mu = 2\text{ GeV}) = (0.995 \pm 0.005)\text{ GeV}$ from the Particle Data Group [41], and take into account the energy-scale dependence of the $\overline{MS}$ masses from the renormalization group

7
\[ m_b(\mu) = m_b(m_b) \left[ \frac{\alpha_s(\mu)}{\alpha_s(m_b)} \right]^{\frac{n_f}{2}}, \]
\[ m_c(\mu) = m_c(m_c) \left[ \frac{\alpha_s(\mu)}{\alpha_s(m_c)} \right]^{\frac{n_f}{2}}, \]
\[ m_s(\mu) = m_s(2\text{GeV}) \left[ \frac{\alpha_s(\mu)}{\alpha_s(2\text{GeV})} \right]^{\frac{3}{2}}, \]
\[ m_u/d(\mu) = m_u/d(1\text{GeV}) \left[ \frac{\alpha_s(\mu)}{\alpha_s(1\text{GeV})} \right]^{\frac{3}{2}}, \]
\[ \alpha_s(\mu) = \frac{1}{b_0 t} \left[ 1 - b_1 \log t + b_2 \left( \log^2 t - \log t - 1 \right) + b_3 b_2 \right], \quad (29) \]

where \( t = \log \frac{M^2}{\Lambda^2}, \quad b_0 = \frac{33 - 2n_f}{12\pi}, \quad b_1 = \frac{153 - 19n_f}{24\pi}, \quad b_2 = \frac{2857 - 103n_f + 47n_f^2}{128\pi^2}, \quad \Lambda = 213 \text{MeV}, \quad 296 \text{MeV} \) and \( 339 \text{MeV} \) for the flavos \( n_f = 5, 4 \) and 3, respectively. Furthermore, we obtain the values \( m_u = m_d = 6 \text{MeV} \) from the Gell-Mann-Oakes-Renner relation at the energy scale \( \mu = 1 \text{GeV} \).

In this article, we choose the \( \mathcal{MS} \) masses by setting \( m = m(\mu) \) and take the perturbative \( \mathcal{O}(\alpha_s) \) corrections to the perturbative terms. In other words, we take the \( R_{SU}(\frac{m^2}{\Lambda^2}) \) only. In calculations, we take \( n_f = 3 \) and \( \mu_{D/D^*} = \sqrt{m_D^2 - m_c^2} \approx 1 \text{GeV} \) for the S-wave mesons \( D \) and \( D^* \); \( n_f = 4 \) and \( \mu_{B/B^*} = \sqrt{m_B^2 - m_b^2} \approx 2.5 \text{GeV} \) for the S-wave mesons \( B \) and \( B^* \). If we count the contribution of the additional P-wave as 0.5 GeV, then \( \mu_{D_s/D_1} = 1.5 \text{GeV} \) and \( \mu_{B_s/B_1} = 3.0 \text{GeV} \). On the other hand, we take into account the SU(3) breaking effect, which is supposed to be 100 MeV for the light quarks, then \( \mu_{D_s/D_1} = 1.1 \text{GeV} \), \( \mu_{B_s/B_1} = 2.6 \text{GeV} \), \( \mu_{D_{s0}/D_{s1}} = 1.6 \text{GeV} \) and \( \mu_{B_{s0}/B_{s1}} = 3.1 \text{GeV} \). Those energy scales work well.

The continuum threshold parameters, Borel parameters, pole contributions are shown explicitly in Table 1. From Table 1, we can see that the pole dominance can be satisfied. On the other hand, the dominant contributions come from the perturbative terms and the quark condensate terms, so we expect to obtain reliable predictions.

After taking into account the uncertainties of the input parameters, we obtain the values of the masses and decay constants of the heavy-light mesons, which are shown in Figs.6-9 and Table 1. From the figures, we can see that the masses and decay constants are rather stable with variations of the Boral parameters \( T^2 \), the predictions are reasonable.

From Table 1, we can see that the experimental values of the masses of the observed mesons \( (D, D^*), (D_s, D_s^*), (D_{s0}(2400), D_1(2430)), (D_{s0}(2317), D_{s1}(2460)), (B, B^*), (B_s, B_s^*) \) can be well reproduced. The masses of the \( (B_{s0}, B_1) \) and \( (B_{s0}^*, B_{s1}) \) vary in rather large ranges from different theoretical approaches, \( m_{B_{s0}} = (5.53 - 5.76) \text{GeV} \), \( m_{B_1} = (5.58 - 5.78) \text{GeV} \), \( m_{B_{s0}^*} = (5.63 - 5.83) \text{GeV} \), \( m_{B_{s1}} = (5.67 - 5.86) \text{GeV} \), for a comprehensive review, one can consult Ref.[45]. The present predictions \( m_{B_{s0}} = (5.72 \pm 0.05) \text{GeV} \), \( m_{B_1} = (5.74 \pm 0.05) \text{GeV} \), \( m_{B_{s0}^*} = (5.70 \pm 0.06) \text{GeV} \), \( m_{B_{s1}} = (5.76 \pm 0.06) \text{GeV} \) are compatible with those values.

The thresholds of the \( DK, D^*K, BK \) and \( B^*K \) states are \( m_{DK} = 2.36 \text{GeV} \), \( m_{D^*K} = 2.50 \text{GeV} \), \( m_{BK} = 5.78 \text{GeV} \) and \( m_{B^*K} = 5.82 \text{GeV} \), respectively. The \( D_{s0}(2317) \) and \( D_{s1}(2460) \) lie below the thresholds \( m_{D^*K} \) and \( m_{D_{s0}^*} \), respectively. The Okubo-Zweig-Iizuka allowed strong decays \( D_{s0}(2317) \rightarrow DK \) and \( D_{s1}(2460) \rightarrow D^*K \) are kinematically forbidden, the widths of the \( D_{s0}(2317) \) and \( D_{s1}(2460) \) are very narrow. According to the present predictions \( m_{B_{s0}} = (5.70 \pm 0.06) \text{GeV} \) and \( m_{B_{s1}} = (5.76 \pm 0.06) \text{GeV} \), the \( B_{s0}^* \) and \( B_{s1} \) also lie below the corresponding \( BK \) and \( B^*K \) thresholds, respectively. The strong decays \( B_{s0} \rightarrow BK \) and \( B_{s1} \rightarrow B^*K \) are kinematically forbidden, the P-wave heavy mesons \( B_{s0}^* \) and \( B_{s1} \) can decay through the isospin violation processes \( B_{s0} \rightarrow B_{s} \eta \rightarrow B_s \pi^0 \) and \( B_{s1} \rightarrow B_{s}^* \eta \rightarrow B_{s}^* \pi^0 \) respectively or through the radiative decays [46]. The \( \eta \) and \( \pi^0 \) transition matrix is very small according to Dashen’s theorem [47].
Figure 6: The masses of the charmed mesons with variations of the Borel parameters $T^2$, the $A$, $B$, $C$, $D$, $E$, $F$, $G$ and $H$ denote the mesons $D$, $D_s$, $D^*$, $D_s^*$, $D_0$, $D_{s0}$, $D_1$ and $D_{s1}$, respectively.
Figure 7: The masses of the bottom mesons with variations of the Borel parameters $T^2$. The A, B, C, D, E, F, G and H denote the mesons $B, B_s, B^*, B_s^*, B_{0}^*, B_{s0}^*, B_1$ and $B_{s1}$, respectively.
Figure 8: The decay constants of the charmed mesons with variations of the Borel parameters \(T^2\), the A, B, C, D, E, F, G and H denote the mesons \(D, D_s, D_s^*, D_s^0, D_0, D_s, D_{s1}\) and \(D_{s1}\), respectively.
Figure 9: The decay constants of the bottom mesons with variations of the Borel parameters $T^2$, the $A$, $B$, $C$, $D$, $E$, $F$, $G$ and $H$ denote the mesons $B$, $B_s$, $B^*$, $B^*_s$, $B_0$, $B_{s0}$, $B_1$ and $B_{s1}$, respectively.
We take the model would modify the decay rates, see Eq.(1), therefore modify the values of the decay constants, rules. The existence of a charged Higgs boson or any other charge d object beyond the standard experimental values of the Table 1: The Borel parameters, continuum threshold parameters, pole contributions, masses and decay constants of the heavy-light mesons.

$$t_{\nu}\langle \pi^0|\mathcal{H}|\eta\rangle = -0.003 \text{ GeV}^2$$, the P-wave bottomed mesons $B_{s1}^*$ and $B_{s1}$, just like their charmed cousins $D_{s0}^*(2317)$ and $D_{s1}(2460)$, maybe very narrow [18]. The present predictions are consistent with our previous work [13], but the analysis is refined by including more terms in the operator product expansion.

The values of the decay constants of the pseudoscalar mesons are slightly different from the ones in our previous work [10]. In Table 2, we compare the present predictions to the experimental data and other theoretical calculations, such the QCD sum rules (QCDRS) [2, 3, 4, 5, 14] and lattice QCD (LQCD) [6, 7, 8]. The present predictions $f_D = (208 \pm 10) \text{ MeV}$ and $f_B = (194 \pm 15) \text{ MeV}$ are consistent with the experimental data within uncertainties, while the prediction $f_{D_s} = (240 \pm 10) \text{ MeV}$ is lies below the lower bound of the experimental value $f_{D_s} = (257.5 \pm 4.6) \text{ MeV}$ [1].

We take the $\overline{MS}$ mass $m_c(\mu)$ and truncate the perturbative corrections to the order $O(\alpha_s)$, the experimental values of the $f_D$, $f_{D_s}$ and $f_{D_s}/f_D$ cannot be reproduced consistently by the QCD sum rules. The existence of a charged Higgs boson or any other charged object beyond the standard model would modify the decay rates, see Eq.(1), therefore modify the values of the decay constants, for example, the lepton decay widths are modified in two-Higgs-doublet models [19]. If the predictions of the $f_D$, $f_{D_s}$ and $f_{D_s}/f_D$ based on the QCD sum rules are close to the true values, new physics beyond the standard model are favored so as to smear the discrepancies between the theoretical calculations and experimental data.

The analytical expression of the perturbative $O(\alpha_s)$ corrections $R_5 \left( \frac{m_\tau^2}{m_\tau^2} \right)$ is well known [17], while the semi-analytical perturbative $O(\alpha_s^2)$ corrections are presented as mathematical functions $R_2\text{FF}[v]$, $R_2\text{FA}[v]$, $R_2\text{FL}[v]$ and $R_2\text{FH}[v]$ with the variable $v = \left(1 - \frac{m_\tau^2}{s}\right)/\left(1 + \frac{m_\tau^2}{s}\right)$ at the energy-scale of the heavy quark pole mass $\mu = m_Q$ [19]. The analytical expressions of the terms which contain logarithms such as $\log \frac{m_\tau^2}{s}$, $\log \frac{m_\tau^2}{s}$ cannot be recovered, it is unreasonable to take other energy scale besides $m_Q$. Now we choose the pole masses $m_Q$ and take into account the semi-analytical perturbative $O(\alpha_s^2)$ corrections by setting $n_f = 4$ and $\mu = m_c$ for the $D$ ($D_s$) meson and $n_f = 5$ and $\mu = m_b$ for the $B$ ($B_s$) meson.

The on-shell quark propagators have no infrared divergences in perturbation theory, which
provides a perturbative definition of the quark masses. The full quark propagators have no poles because the quarks are confined, so the pole masses cannot be defined outside of perturbation theory. Furthermore, the pole masses cannot be used to arbitrarily high accuracy because non-perturbative infrared effects in QCD. We choose the pole masses just because the semi-analytical perturbative $\mathcal{O}(\alpha_s^2)$ corrections are calculated by taking the pole mass $m_Q$ and setting the energy scale to be $\mu = m_Q$ [19]. The contributions of the $u, d$ masses are tiny and can be neglected safely. In calculations, we set the pole masses $m_u = m_d = 0, m_s = 150$ MeV, and observe that the masses of the heavy pseudoscalar mesons increase monotonously with increase of the pole masses, the values of the pole masses $m_c = 1.44$ GeV and $m_b = 4.67$ GeV can lead to satisfactory values by choosing reasonable Borel parameters and threshold parameters. Those pole masses are different from the $\overline{MS}$ masses, for example, $m_c(\mu = 1$ GeV) = 1.39 GeV, $m_b(\mu = 1$ GeV) = 6.07 GeV, $m_u(\mu = 2$ GeV) = 1.13 GeV, $m_b(\mu = 2$ GeV) = 4.87 GeV from Eq.(29). The pole masses are energy scale independent, therefore the energy scale dependence of the QCD spectral densities originate only from the vacuum condensates.

The Borel parameters, continuum threshold parameters, pole contributions, and the resulting masses and decay constants of the heavy pseudoscalar mesons are shown in Table 3, the values are slightly different from the ones in our previous work [10]. From Table 1 and Table 3, we can see that the present predictions $f_D = (210 \pm 11)$ MeV, $f_D = (259 \pm 10)$ MeV and $f_B = (192 \pm 13)$ MeV are in excellent agreement with the experimental data within uncertainties [11]. The ratio $f_D/f_D = 1.23 \pm 0.07$ is also in excellent agreement with the experimental data $f_D/f_D = 1.258 \pm 0.038$ [11], which indicates that the perturbative $\mathcal{O}(\alpha_s^2)$ corrections should be taken into account. However, the pole masses $m_Q$ and energy scales $\mu = m_Q$ have been chosen, as the semi-analytical expressions are obtained at such conditions. In this case, new physics beyond the standard model are not favored, as the agreements between the experimental data and present theoretical calculations are already excellent.

In Table 4, we compare the present predictions for the decay constants of the heavy vector mesons to other theoretical calculations, such as the QCD sum rules [5 15 21], lattice QCD [22 23 24 25], the relativistic potential model (RPM) [30], the field-correlator method (FCM) [32], and the light-front quark model [34]. From the table, we can see that the predictions differ from each other in one way or the other. In Table 5, we compare the present predictions for the decay constants of the heavy scalar mesons to the ones from the QCD sum rules [16] and lattice QCD [26]. From the table, we can see that the predictions are consistent with the ones from lattice calculations but differ greatly from the ones from the QCD sum rules.

If we turn off the perturbative $\mathcal{O}(\alpha_s)$ corrections to the quark condensates and choose the same parameters, such as the $\overline{MS}$ masses, Borel parameters and continuum threshold parameters, etc, the masses and decay constants undergo reduction or increment in a definite way according to the spin and parity, see Table 6. From the table, we can see that the mass-shifts of the $D$-mesons with $J^P = 0^\pm$ are larger than 40 MeV, while the shifts of the masses and decay constants of all the $B$-mesons are small and can be neglected. We can re-choose the Borel windows to warrant the mass-shifts $\delta m_{S/P/V/A} = 0$, and account for the net effects by the shifts of the decay constants $\delta f_{S/P/V/A}$, which are shown the bracket in Table 6. From the table, we can see that the largest shift of the decay constant $\delta f_D = -11$ MeV, which exceeds the total uncertainty of the decay constant $\delta f_D = \pm 10$ MeV (see Table 1), the shifts of the decay constants of the $D$-mesons with $J^P = 0^\pm, 1^-$ are larger than 5 MeV, while for other mesons, the shifts of the decay constants $|\delta f| \leq 4$ MeV. All in all, we should take into account the perturbative $\mathcal{O}(\alpha_s)$ corrections to the quark condensates in a comprehensive study.

4 Conclusion

In this article, we calculate the contributions of the vacuum condensates up to dimension-6, in including the $\mathcal{O}(\alpha_s)$ corrections to the quark condensates, in the operator product expansion. Then
Table 2: The decay constants of the heavy pseudoscalar mesons from the experimental data, the
QCD sum rules and lattice QCD, the superscript star * denotes that the pole masses are chosen
and perturbative $O(\alpha_s^2)$ corrections are taken into account.

we study the masses and decay constants of the pseudoscalar, scalar, vector and axial-vector heavy-light mesons with the QCD sum rules in a systematic way. In calculations, we take the MS masses and take into account the perturbative $\mathcal{O}(\alpha_s^2)$ corrections by choosing the pole masses, then the experimental data can be well reproduced. The present predictions for the decay constants of the heavy-light pseudoscalar, scalar, vector and axial-vector mesons have many phenomenological applications in studying the semi-leptonic and leptonic decays of the heavy-light mesons.
