The Protective Role of Alpha Lipoic Acid Against pesticides Induced Testicular Toxicity- Histopathological and Histochemical Studies

Azza M. Gawish
Department of Zoology, Faculty of Science, Cairo University, Giza, Egypt

Abstract

The present study aimed to investigate the efficiency of alpha-lipoic acid (ALA) as a natural antioxidant in ameliorating some of the changes induced by intoxication with a mixture of well-known pesticides used in our agricultural media. Four groups of male rats were treated as follows: untreated control animals, (P-mix), consists of 1/60LD50 chlorpyrifos (2mg/Kg b.wt) 1/200 LD50 of fenitrothion (2.5 mg/km b.wt) as used in agricultural environment and ALA 200mg/animal of alpha lipoic acid, (P-mix+ALA). Histological observation of the intoxicated rats revealed significant alterations in the testis tissue of P-mix treated group including focal mild testicular damage, blood hemorrhage and hypopospermato genesis, necrosis and atrophy. The degree of fibrosis was encountered using masson-trichrome stain technique which revealed various fibrosis grades between the control and treated testes tissues upon the exposure to the insecticides. TUNEL technique showed an increase in the incidence of positive apoptotic cells between the spermatogonial and germ cells. Also complete depletion of the level of acid phosphatase enzyme which involved in the testosterone biosynthesis. The treatment with alpha lipoic acid showed many degrees of improvements in the seminiferous tubules, spermatogenic germ cells and the interstitial cells. Also decrease in the grades of fibrosis between testis tissues. Conclusion: The biochemical, histopathological, reports supported that the pesticides have many implicated toxic changes on the testes tissues and the antioxidants like alpha lipoic acid obtained many trials to get ameliorative effects on the toxicity of pesticides.

Keywords: Pesticides; Reproduction; Apoptosis; Fibrosis; Antioxidants

Introduction

Chlorpyrifos, first introduced into the marketplace in 1965, has been widely used globally as an insecticide to control crop pests in agriculture, reduce household pests such as termites, reduce insect damage, and for mosquito control. Fenitrothion is approved as a broad-spectrum organophosphorus pesticide. Its toxicity was first evaluated by 1969. Problems associated with pesticides hazards to man and environment are not confined to the developing countries, but extended to developed nations and still facing some problems in certain locations [1]. It has many structural actions of insecticides as the inhibition of the release of the acetylcholonesterase at the synaptic junction [2]. Several studies showed that organophosphorous as malathion and chlorpyrifos induced various physiological, biochemical, immunological and histological changes in experimental animals [3]. The widespread usage of organophosphates has stimulated research to the existence of effects related with their reproductive toxic activity [4].

Hileman [5] reported that fenitrothione have the potential to cause reproductive toxicity in animals, affect human reproduction. Okamura and Presibella [6-7] showed some pathological effects of pesticides on the reproductive system of experimental animals. Chlorpyrifos had been obtained testicular damage, damage to sperm production, and reduction in testosterone levels when fed to adult male rats [8]. There is growing concern that pesticide as chlorpyrifos have estrogenic property, may be causing a variety of reproductive disorders in wildlife and human population [9].

Gangadharan [10] reported that organophosphorous have been shown to produce reactive oxygen species (ROS) in both intra and extra cellular spaces, resulting in decline of sperm count and infertility in wildlife and human. Chlorpyrifos was showed severe testicular damage and results in reduction in sperm count affecting fertility [11]. Chlorpyrifos (CP) and Fenitrothion, are organophosphorous insecticides, have postulated a possible role for the generation of free radicals and induction of oxidative stress [12]. Suskind [13] reported a significant correlation between increased fibrosis and both reduced tubular diameter and fewer germ cells.

Apoptosis or programmed cell death is an active process controls cell numbers in a variety of tissues and at various phases of germ cell development [14]. Many studies reported that many organophosphorous like chlorpyrifos caused withdrawal of gonadotropins and/or testosterone which enhances the germ cell degeneration and apoptosis of germ cells in the testis [14-17].

Lipoic acid is an organ sulfur compound, which is an essential cofactor for many enzyme complexes and the the amount of lipoic acid present is very low. Naturally occurring lipoic acid is always covalently bound and not immediately available from dietary sources. Studies are generally dealing with the biological consequences of lipoic acid administration and its derivatives in cases associated with oxidative stress [18-20]. An attempt was made to elucidate the possible protective effect of lipoic acid treatment on pesticides-induced physiological and histopathological alterations in rats with testicular toxicity. Chlorpyrifos exposed rats showed abnormal levels of antioxidants enzymes In contrast, rats pretreated with lipoic acid is an organ sulfur compound, which is an essential cofactor for many enzyme complexes and the the amount of lipoic acid present is very low. Naturally occurring lipoic acid is always covalently bound and not immediately available from dietary sources. Studies are generally dealing with the biological consequences of lipoic acid administration and its derivatives in cases associated with oxidative stress [18-20]. An attempt was made to elucidate the possible protective effect of lipoic acid treatment on pesticides-induced physiological and histopathological alterations in rats with testicular toxicity. Chlorpyrifos exposed rats showed abnormal levels of antioxidants enzymes In contrast, rats pretreated with lipoic acid obtained many trials to get ameliorative effects on the toxicity of pesticides.
acid showed normal lipid peroxidation and antioxidant defenses. These findings indicate a cytoprotective role of lipoic acid in this experimental model of testicular toxicity [21]. Present study was taken to assess the effects of chlorpyrifos and fenitrothion on testes, the main organ of male reproduction and the possible ameliorative effect of naturally occurring antioxidants like alpha lipoic acid.

Materials and Methods

Animals and experimental design

Animals: Male albino rats Rattus norvegicus (3–4) month’s age, weighing between 150–180 g were used. Animals were supplied by the breeding unit of the Egyptian Organization for the Biology and Vaccine Production, Egypt. The animals were housed in plastic cages, fed ad libitum and allowed to adjust to the new environment for two weeks before starting the experiment. The rats were housed at 23 ± 2°C dark/light cycle.

Chemicals

Chlorpyrifos: Pyrihan(chlorpyrifos48%EC)(O,O-Diethyl-O(3,5,6-trichloro-2-pyridyl phosphorothioato) was supplied by El Help company for pesticide industry- Egypt.

Fenitrothion: Sumition (Fenitrothion 50% EC)(O,O-dimethyl O-4-nitro-m-tolyl phosphorothioato) was purchased from Kaffer Elzayat Co. for Insecticide Ind. Kaffi Elzayat, Egypt.

Antioxidant used: Alpha lipoic acid.

Experimental Design

All animals were treated according to the standard procedures laid down by OECD guidelines 407 (1992) repeated dose 28 days oral toxicity study in rodents. Animals were randomly divided into six experimental groups, five animals each as follows:

Group 1 (control): Each animal in this group was given distilled water (1ml/animal) by gastric incubation every day for 28 days.

Group 2 (P-mix): rats were orally treated via gastric intubation with mixture of pesticides mixture contain (1/60 LD₅₀ chlorpyrifos (2mg/Kg b.wt, 1/200 LD₅₀ of fenitrothion= 2.5 mg/k gm b.wt every day for 28 consecutive days.

Group 3 (ALA): rats were orally supplemented with 60mg /Kg for 28 days and served as an control. 4-Group (P-mix + ALA): rats were orally supplemented with (60 mg /Kg) ALA 1 hour after intoxication with pesticides mixture.

Sampling

Blood samples collected from the retro-orbital plexus vein according to Schermer (1967). On heparinized tubes at 28 days of treatment periods, plasma samples were separated by centrifugation of the blood samples at 3600 rpm for 15 min. Plasma samples were kept at -20 °C for subsequent use. At the end of the experiment, animals were dissected and samples of the testes were subjected to the histopathological and histochemical studies.

Biochemical assay: Malondaldehyde (MDA) enzyme was measured according to Ohkawa et al., [22], in the plasma after incubation at 95°C with thiobarbituric acid in aerobic conditions (pH 3.4). Testosterone hormone level was measured in the plasma according to Tremblay et al., [23].

Histological studies: Animals were sacrificed after 24 hour of treatment. The testis was dissected and fixed immediately in neutral buffered formalin (10%) and paraffin sections were prepared and stained with hematoxylin and eosin, and Masson-trichrome stain was used showing collagen and elastic fibers changes according to Bancroft and Gamble [24].

2- Assessment of apoptosis

Evaluation of apoptosis in testis tissue homogenate was achieved by quantification of cytoplasmic histone-associated DNA fragments using cell death Detection ELISA plus kit (Roche). One ml of testis tissue was transferred into 1 volume incubation buffer (7% paraformaldehyde) and homogenized. According to the kit manufacturer’s guidelines (Roche), homogenized samples were centrifuged at 13000 rpm for 10 min at 4°C, the supernatant was removed carefully, and the pellet was resuspended in 200 µl incubation lysis buffer, and incubated for 30 min at room temperature. It should be noticed that several dilutions of testis tissue were assayed to determine the appropriate concentration required for ELISA as a preliminary test. Then the lysate was centrifuged at 200x g for 10 min, the supernatant (cytoplasmic fraction) 20µl/well was transferred carefully into the streptavidin-coated micro-titer plate (MTP) for analysis; samples were added in duplicates. Positive, blank and background controls were treated similarly as the samples. The immunoreagent was prepared by mixing 1/20 volume antihistone-biotin with 1/20 volume anti-histone with 18/20 volume incubation buffer (v:v:v), then 80µl/well of the prepared reagent were added to MTP. The plate was incubated (covered with adhesive foil) on MTP shaker under gentle shaking for 2 hrs at room temperature. Then, the solution was well rinsed in 250 µl incubation buffer. The reaction was visualized by adding 100 µl/well of the freshly prepared substrate ABTS, incubated for 15 min on a plate shaker at 250 rpm until the colour development is sufficient for photometric analysis. The absorbance was recorded at 405 nm against ABST as a blank (reference wave length approx. 490 nm). Unless otherwise stated, all reagents and supplements were supplied with the kit. The concentration of nucleosomes in the sample reflects the amount of cell death. Increases in DNA fragmentations over control values (blank and background) were measured and expressed as OD Δ450–490

TUNEL staining

To detect cells undergoing apoptosis, the tissue sections were stained according to the TUNEL procedure [25], with some modifications. Briefly, the testes tissues was immediately fixed in 4% paraformaldehyde at 4°C for 20 – 22 h and embedded in paraffin. The tissue was sectioned at 4μm, dewaxed, rehydrated, and digested with 20µg/ml of proteinase K (Sigma), Endogenous peroxidase was blocked by treatment in 0.3 % hydrogen peroxide. The sections were then rinsed in water and incubated with 50µl of terminal deoxynucleotidyl transferase buffer in a moist chamber at 37°C for 60 min. The sections were then rinsed and 50µl converter-POD was added on each tissue sample, covered, and incubated for 30 min at 37°C. For colour development the slides were rinsed in PBS, then 50µl DAB-substrate (Roche) solution were added, incubated in dark for 10 min at room temperature, washed, counterstained with haematoxylin, dehydrated and finally coverslips were mounted.

Histochemical study: The specimens were subjected to the fixation with frornl – calcium and acid phosphatase was detected due to Gomori-lead method in which acid phosphatase activity acquire black colour and the nuclei acquired green colours according to Bancroft and Stevens.

Result

Biochemical studies

The expressed data in (Table 1) declared that in addition to the
classical mechanism of pesticides there is an enhancement for the free radicals that expressed by significant elevation in oxidative stress biomarker malondialdehyde (MDA) versus control at p< 0.05. On the other hand, consecutive supplementation with ALA for 28 days alone or in combination with pesticides induced observable significant reduction in plasma MDA level, this significant was versus control and P-mix treated groups at p< 0.05. As regards to plasma testosterone level repeated intoxication with p mix induced remarkable significant reduction versus control in plasma testosterone level at p<0.05.). However, supplementation with ALA improves the toxic effect of p mix that was significant versus control and P-mix groups.

| Parameter | Groups | Con. | P-Mix | ALA (+ve C) | ALA+ P-mix |
|-----------|--------|------|-------|-------------|------------|
| MDA (μmol/dl) | 17.22 ± 1.77 | 31.71 ± 1.66a | 19.97 ± 3.57 | 21.96 ± 2.99 |
| Testosterone (ng/dl) | 211.699 ± 20.11 | 143.043 ± 11.16a | 207.699 ± 16.22 | 192.779 ± 19.27ab |

All data were expressed as mean ± SE.
*significant difference versus control at P<0.05.
*significant difference versus control at P<0.05.
*significant difference versus control at P<0.05.
MDA: malondialdehyde.

**Table 1:** Effect of Alpha Lipoic Acid supplementation on Different biochemical parameters in plasma of male albino rats intoxicated with mixture of pesticides(cp+fn).

**Histopathological observations**

**A)** Examination of sections of the testes with haematoxylin and eosin stain revealed normal architecture of seminiferous tubules, normal arrangement of spermatogenic cells germ cells and well arranged and distributed interstitial cells in the peritubular areas (Figure 1). The second group of rats was treated with (60mg/kg b.wt.) of alpha-lipoic acid served as positive control showed nearly normal appearance of the seminiferous tubules and Leydig cells (Figure 2). Upon the toxicity with (P-mix, consists of, 1/60LD50 chloropyrifos and 1/200 LD50 of fenitrothion) showed infoldings of the membranes of seminiferous tubules, degeneration of the spermatogenesis process and hemorrhage between the seminiferous tubules (arrows). When the rats treated with alpha-lipoic acid after the toxicity with the pesticides mixtures, the testis tissues revealed some degeneration between the germ cells of the tubules and well arranged interstitial cells (Figure 6 and Figure 7) and well organized.

**Figure 4:** Photomicrographs of testes sections of rats treated with insecticide mixture of (1/60 of LD50 of chlorpyrifos and 1/200 LD50 of fenitrothion) showed infoldings of the membranes of seminiferous tubules, degeneration of the spermatogenesis process and hemorrhage between the seminiferous tubules (arrows).

**Figure 5:** Photomicrograph of testes sections of rats also treated with pesticide mixture obtained more proliferation within the interstitial cells (arrows).

**Figure 6:** Photomicrograph of testes sections of rats intoxicated with the pesticide mixture and treated with ALA revealed some amelioration of the hypospermatogonia in the seminiferous tubules (S6) and giant cells between the Leydig cells (arrows).
fibrosis around the testis section (Figure 9). The pesticides mixture treatment obtained higher grades of fibrosis surrounding the testis section (Tunica albuginea) and in the peritubular areas (Figure 10 and Figure 11). Supplementation of alpha lipoic acid after the toxicity of pesticides mixture showed testis tissues with minimal fibrosis (Figure 12).

**Immunohistochemical results**

Testes sections of all groups were subjected to terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling of tissue sections TUNEL for the detection of apoptosis. The testis tissue of the untreated control rats showed normal significant positive cells (Figure 13). Upon supplementation with alpha lipoic acid alone the testis tissue revealed mild increase in the positive cells between their germ cells (Figure 14). The testis section of the animals intoxicated with pesticides mixture obtained significant highly positive cells between all the stages of spermatogenesis cells (Figure 15). Mild improvement of the apoptotic positive cells was recorded within the testis tissue of the rats treated with alpha lipoic acid after the intoxication with pesticides mixture (Figure 16).

**Histochemical observations**

Acid phosphatase enzyme was detected in all testes sections of the animals using Gomori lead method. Untreated animals recorded the distribution of acid phosphatase in the primary and secondary spermatocytes as brown granules (Figure 17). The animals treated with alpha-lipoic acid (served as + control group) showed nearly normal level of the brown granules of acid phosphatase enzyme (Figure 18). Animals treated with the pesticides mixture obtained complete fibrosis around the testis section (Figure 9). The pesticides mixture treatment obtained higher grades of fibrosis surrounding the testis section (Tunica albuginea) and in the peritubular areas (Figure 10 and Figure 11). Supplementation of alpha lipoic acid after the toxicity of pesticides mixture showed testis tissues with minimal fibrosis (Figure 12).

**Immunohistochemical results**

Testes sections of all groups were subjected to terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling of tissue sections TUNEL for the detection of apoptosis. The testis tissue of the untreated control rats showed normal significant positive cells (Figure 13). Upon supplementation with alpha lipoic acid alone the testis tissue revealed mild increase in the positive cells between their germ cells (Figure 14). The testis section of the animals intoxicated with pesticides mixture obtained significant highly positive cells between all the stages of spermatogenesis cells (Figure 15). Mild improvement of the apoptotic positive cells was recorded within the testis tissue of the rats treated with alpha lipoic acid after the intoxication with pesticides mixture (Figure 16).
depletion in the brown granules of acid phosphatase enzyme. (Figure 19) compared to the untreated animals. Alpha – lipoic acid treatment with the pesticides mixture showed mild ameliorative effect on the concentration of the enzyme granules (Figure 20) compared to the pesticides treated group.

**Discussion**

The testicular toxicity of insecticides was proven and alternative harmless control strategies should be applied. Insecticides were proven to be induced sever testicular toxicity as shown in the histopathological results which coupled with marked changes of biochemical results. Our results obtained spermatogonial depletion and atrophy due to pesticides toxicities in the seminiferous tubules. We detected desquamated cells in the lumen of seminiferous tubules and vacuolization within germ cells and some tubules contain apoptotic bodies, at the end of treatment, Leydig cells are strongly regressed and spermatozoa are less present in the luminal aspect of the seminiferous tubules. Also thickened basement membrane accompanied by disappearance of interstitial cells and Leydig cells were proven.

There are several possible mechanisms for the antagonald actions of organophosphorous in which they may exert a direct inhibitory action on the testis; they may affect the pituitary causing changes in gonadotropin concentration, and may change the concentration of the neurotransmitter acetylcholine [26-27]. The hazardous effect of these pesticides on semen quality continued during the post treatment period, and was dose-dependent[28]. Therefore Roy et al., [2] showed that quinalphos may exert a suppressive effect on the functional activity of accessory sex glands by decreasing testicular testosterone production following inhibition of pituitary gonadotrophins release[29]. Exposure to low level organophosphorous is known to produce a variety of biochemical changes, some of which may be responsible for the adverse biological effects reported in humans and experimental animals [30].

As it was shown that, fibrosis correlates with these histological finding, and implicated with the pathological changes. Fibrosis is probably the end result of an inflammatory process. Cell death also occurs spontaneously at various phases of germ cell development and morphological studies have implicated apoptosis in spermatogonial death appears to play a major role during spermatogenesis [14]. The spermatogenesis in mammals depends on testosterone production.
by Leydig cells in response to stimulation by FSH and LH. FSH increases Sertoli cell synthesis of an androgen binding protein needed to maintain high concentrations of testosterone. LH stimulates testosterone production by the interstitial cells of the testis [31].

Sugar [32] obtained that acid phosphatase enzyme plays an important role in the process of cell metabolism, autolysis, differentiation and many related processes and the dilatation of blood capillaries in between seminiferous tubules obtained upon the result of acid phosphatase enzyme activity. The increase in acid phosphatase enzyme activity could be explained on the bases of enhancement of cell membrane permeability with disturbance in the transphosphorylation process as a result of cellular degeneration [33-34].

The depletion of the enzymatic antioxidative system strengthens the oxidative damage of membranes plays a significant role in cellular damage into the testes [35-36]. Pesticides may induce oxidative stress, leading to generation of free radicals and alteration in antioxidants, oxygen free radicals, the scavenging enzyme system, and lipid peroxidation [37-38].

Lipoic acid was first postulated to be an effective antioxidant [39-42]. It is able to scavenge reactive species in vitro, though there is little or no evidence that this actually occurs in vivo. Alpha Lipoic Acid works both inside the cell and at the membrane level, thereby giving dual protection. [43] obtained the ability of ALA to create a robust shield on the cell membrane of sperm, along with the liquid that surrounds the sperm indirectly enhance the ability of the sperm to tolerate higher volumes of free radical attack. ALA has also been reported to assist the mitochondria’s citric cycle; this in turn will increase the level of reduced glutathione, ATP, TCA cycle enzyme and electron transport chain complex activities [44, 20]. ALA regulation of metabolism, increased availability of mitochondrial co-enzymes and improvement of protection of free radicals are thought to eventually lead to a reduced incidence of mitochondria dysfunction, thus ensuring sufficient ATP for sperm movement [11]. In conclusion, the toxicity of the pesticides mixture was shown atrophy, fibrosis and increase the incidence of the apoptosis on the testes tissues then, on the fertility and spermatogenesis process. Also, alpha lipoic acid treatment revealed mild ameliorative effect on the pathology of testes [45-70].
