Abstract

In a series of papers, we have investigated the compatibility of the Kimber-Martin-Ryskin (KMR) and Martin-Ryskin-Watt (MRW) unintegrated parton distribution functions (UPDF) as well as the description of the experimental data on the proton structure functions. The present work is a sequel to that survey, via calculation of the transverse momentum distribution of the electro-weak gauge vector bosons in the $k_t$-factorization scheme, by the means of the KMR, the LO MRW and the NLO MRW UPDF, in the next-to leading order (NLO). To this end, we have calculated and aggregated the invariant amplitudes of the corresponding involved diagrams in the NLO, and counted the individual contributions in different frameworks. The preparation process for the UPDF utilizes the PDF of Martin et al, MSTW2008 – LO, MSTW2008 – NLO, MMHT2014 – LO and MMHT2014 – NLO as the inputs. Afterwards, the results have been analyzed against each other, as well as the existing experimental data. Our calculation show excellent agreement with the experiment data. It is however interesting to point-out that, the calculation using the KMR framework illustrates a stronger agreement with the experimental data, despite the fact that the LO MRW and the NLO MRW formalisms employ a better theoretical description of the DGLAP evolution equation. This is of course due to the use of the different implementation of the angular ordering constraint in the KMR approach, in which automatically includes the re-summation of $\ln(1/x)$, BFKL logarithms, in the LO-DGLAP evolution equation.

I. INTRODUCTION

In the recent years, new discoveries have been made at many high energy particle physics laboratories, including the LHC, concerning physics within the boundaries of the Standard Model and beyond, as the consequence of pushing the maximum energy of the experiments to the new limits. Today, many of these laboratories use parton distribution functions (PDF) to describe and analysis their extracted data from the deep inelastic QCD collisions. These scale-dependent functions are the solutions of the Dokshitzer-Gribov-Lipatov-Altarelli-Parisi (DGLAP) evolution equations, [1–4],

$$\frac{d a(x, Q^2)}{d \log(Q^2)} = \frac{\alpha_s(Q^2)}{2\pi} \sum_{b=q,g} \left[ \int_x^1 dz P_{ab}(z)b(\frac{x}{z}, Q^2) - a(x, Q^2) \int_0^1 dz z P_{ba}(z) \right], \quad (1)$$

where $a(x, Q^2)$ can be either the distribution function of the quarks, $xq(x, Q^2)$, or that of the gluons, $xg(x, Q^2)$, with $x$ being the fraction of the longitudinal momentum of the parent hadron (the Bjorken variable). The terms on the right-hand side of the equation (1), correspond to the real emission and the virtual contributions, respectively. The scale $Q^2$ is an ultra-violet cutoff, related to the virtuality of the exchanged particle during the deep inelastic scattering (DIS). $P_{ab}(z)$ are the splitting functions of the respective partons which account for the probability of emerging a parton $a(x'', Q^2)$ from a parent parton $b(x', Q^2)$ through $z = x''/x'$.

The DGLAP evolution equation however, is based on the strong ordering assumption, which systematically neglects the transverse momentum of the emitted partons along the evolution ladder. It has been repeatedly hinted that undermining the contributions coming from the transverse momentum of the partons may severely harm the precision of the calculations, especially in the high energy processes in the small-$x$ region, see for example the references [5–9]. This signaled the necessity of introducing some transverse momentum dependent parton distribution functions (TMD PDF), initially through the Ciafaloni-Catani-Fiorani-Marchesini (CCFM) equation [10–14],

$$f(x, k_t^2, Q^2) = f_0(x, k_t^2, Q^2) + \int_x^1 dz \int \frac{dq^2}{q^2} \Theta(Q - zq) \Delta_S(Q, q) \times P(z, \tilde{\alpha}_s(k_t^2)) f\left(\frac{x}{z}, |k_t + (1-z)q|^2, q^2\right). \quad (2)$$

The $\Theta(Q - q)$ implies a physical condition, enforcing the increase of the angle of the emission of the gluons in successive radiations along the evolution chain.
which is usually referred to as the angular ordering constraint (AOC), is due to the coherent radiation of the gluons. The Sudakov form factor, $\Delta_S(Q, q)$, gives the probability of evolving from a scale $q$ to a scale $Q$, without any partons emission, and can be defined as:

$$\Delta_S(Q, q) = \exp \left( -\bar{\alpha}_s \int_{q^2}^{Q^2} \frac{dk^2}{k^2} \int_0^1 dz' \frac{1}{(1-z)} \right),$$  \hspace{1cm} (3)

with $\bar{\alpha}_s = 3\alpha_s/\pi$. In the equation (2), $f(x, k_t^2, \mu^2)$ is the double-scaled CCFM TMD PDF, which in addition to the $x$ and $Q$, depends on the transverse momentum of the incoming partons, $k_t$. It has been shown (see the reference [15]) that in the proper boundaries, the CCFM equation will reduced to the conventional DGLAP and Balitski-Fadin-Kuraev-Lipatov (BFKL) equations, [16–20].

The procedure of solving the CCFM equation is mathematically involved and unrealistically time consuming, since it includes contemplating iterative integral equations with many terms. On the other hand, the main feature of the CCFM equation, i.e. the AOC, can be exclusively used for the gluon evolution and therefore, this process is incapable of producing convincing quark contribution. To overcome these obstacles, Martin et al have introduced the $k_t$-factorization framework and developed the Kimber-Martin-Ryskin (KMR) and the Martin-Ryskin-Watt (MRW) approaches [5, 6], both of which are constructed around the LO DGLAP evolution equations and modified with the different visualizations of the angular ordering constraint. The frameworks of KMR and MRW in the LO and NLO have been investigated intensely in the recent years, see the references [21–28].

Although Martin et al have developed the MRW formalism as an improvement to the KMR approach, by correcting the use of the AOC, limiting its effect only on the diagonal splitting functions and extending the range of their calculations into the NLO via introducing the NLO MRW scheme, it appears that the KMR approach, as an effective model, is more successful in producing a realistic theory in order to describe the experiment. We are therefore eager to expand our investigation regarding the merits and shortcomings of these frameworks into the calculation of the inclusive cross-sections of production of the electro-weak gauge bosons in high energy hadronic collisions.

The process of the production of the massive gauge vector bosons, $W^\pm$ and $Z^0$, have always been of extreme theoretical and experimental interest, since it can provide invaluable information about the nature of both the electro-weak and the strong interactions, setting a benchmark for testing the validity of the experiments and establishing a firm base for test-
ing new theoretical frameworks, see the references [29–39]. It is not however straightforward to describe the transverse momentum distributions of the electro-weak bosons produced in hadron-hadron collisions, since the usual collinear factorization approach in the LO, neglects the transverse momentum dependency of the incoming partons and therefore predicts a vanishing transverse momentum for the product. Consequently, initial-state $QCD$ radiation is necessary to generate the $k_\perp$ distributions. On the other hand, in this approximation, calculations for differential cross sections of the $W^\pm$ and $Z^0$ production diverge logarithmically in the $NLO$ limit for the $k_\perp \ll M_{W,Z}$ (which is the main region of interest), due to the soft gluon emission. So, one requires a re-summation to obtain a finite $k_\perp$ distribution.

In the present work we tend to calculate the $k_\perp$ distributions of the cross-section of production of the $W^\pm$ and $Z^0$ using the $NLO$ level diagrams and the $LO$ and $NLO$ $UPDF$ of the $KMR$ and the $MRW$ frameworks. The $UPDF$ will be prepared in their proper $k_\perp$-factorization schemes using the $PDF$ of $MSTW2008−LO$, $MSTW2008−NLO$, $MMHT2014−LO$ and $MMHT2014−NLO$, [40–43]. Such calculations have been previously carried out using $LO$ matrix elements of quark-antiquark annihilation cross section and doubly-unintegrated parton distribution functions ($DUPDF$) in the framework of $(k_\perp,z)$-factorization, reference [9], and in a semi-$NLO$ approach, using a mixture of $LO$ and $NLO$ matrix elements for the involved processes in addition to a variety of $TMD \ PDF$, see the reference [38]. To improve these approximations and at the same time, test the functionality of the $KMR$ and the $MRW \ UPDF$, we have calculated the $NLO$ ladder diagrams for $g+g\to W^\pm/Z^0+q+q\,'$, $q+g\to W^\pm/Z^0+q\,'+g$ and $q+q\,'\to W^\pm/Z^0+g+g$, utilizing a physical gauge for the gluons. In this way, at the price performing long and complicated calculations, we will demonstrate that with the use of the $UPDF$ in the $NLO$ calculations, one can extract an excellent description of the experimental data of the $D0$ [5,8,9] and $CDF$ [4] collaborations, as well as others works given here, regarding the transverse momentum distributions of the $W^\pm$ and $Z^0$ boson.

In what follows, first, a brief introduction to the concept of $k_\perp$-factorization will be presented and the respective formalisms for the $KMR$ and the $MRW$ frameworks will be derived, in the section 2. The section 3 contains a comprehensive description over the utilities and means for the calculation of the $k_\perp$-dependent cross-section of production of the $W^\pm$ and $Z^0$ gauge vector bosons in a hadron-hadron (or hadron-antihadron) deep inelastic collision. The necessary numerical analysis will be presented in the section 4, after which a
thoroughgoing conclusion will be followed in the section 5.

II. THE $k_t$-FACTORIZATION SCHEME

A parton entering the sub-process at the top of the evolution ladder, has non-negligible transverse momentum. However, it is customary to use the PDF of the DGLAP or the BFKL evolution equations to describe such partons, despite the fact that these density functions intrinsically carry no $k_t$-dependency. To include the contributions coming from the transverse momentum distributions of the partons, one can either use the solutions of the CCFM evolution equation or unify the BFKL and the DGLAP evolution equations to form a properly tuned $k_t$-dependent framework, \[44, 45\]. Nevertheless, given the mathematical complexity of these schemes, it is not desirable to use them in the task of computing the DIS cross-sections. Another way is to convolute the single-scaled solutions of the DGLAP evolution equation and insert the required $k_t$-dependency via the process of $k_t$-factorization (for a complete description see the reference \[8\]).

Thus, one may define the $UPDF$, $f_a(x, k_t^2, \mu^2)$, in the $k_t$-factorization scheme, through the following normalization relation,

$$a(x, \mu^2) = \int \frac{d k_t^2}{k_t^2} f_a(x, k_t^2, \mu^2),$$

where $a(x, \mu^2)$ are the solutions of the DGLAP equation and stand for either $xq(x, \mu^2)$ or $xg(x, \mu^2)$. The procedure of deriving a direct expansion for $f_a(x, k_t^2, \mu^2)$, in terms of the PDF is straight forward. Yet, exposing the resulting prescriptions to the different visualizations of the AOC will produce different $UPDF$, namely the KMR, the LO MRW and the NLO MRW frameworks. In what follows, we will describe these frameworks in detail.

A. The KMR framework

Starting from the DGLAP equation in the leading order, the equation \(1\), and using the unregulated LO DGLAP splitting kernels, $P_{ab}(z)$, the reference \[46\], Kimber et al introduced an infrared cut-off, $\Delta$, as a visualization of the AOC \[47\],

$$\Theta(\theta - \theta') \implies \mu > \frac{zk_t}{(1 - z)} \implies \Delta = \frac{k_t}{\mu + k_t}.$$
Limiting the upper boundary on \( z \) integration by \( \Delta \), excludes \( z = 1 \) from the integral equation and automatically prevents facing the soft gluon singularities arising from the \( 1/(1-z) \) terms in the splitting functions. Additionally, they factorized the virtual contributions from the DGLAP equations, by defining a virtual (loop) contributions as:

\[
T_a(k_t^2, \mu^2) = \exp \left( -\int_{k_t^2}^{\mu^2} \frac{\alpha_S(k^2)}{2\pi} \frac{dk^2}{k^2} \sum_{b=q, g} \int_0^{1-\Delta} dz' P_{ab}^{(LO)}(z') \right),
\]

with

\[
T_a(\mu^2, \mu^2) = 1,
\]
as an appropriated form of the Sudakov form factor, the equation (3). Afterwards, the double-scaled KMR UPDF are defined as follows:

\[
f_a(x, k_t^2, \mu^2) = T_a(k_t^2, \mu^2) \sum_{b=q, g} \left[ \alpha_S(k_t^2) \frac{1}{2\pi} \int_x^{1-\Delta} dz P_{ab}^{(LO)}(z) b \left( \frac{x}{z}, k_t^2 \right) \right].
\]

According to the above formulation, only at the last step of the evolution, the dependence on the second scale, \( \mu \), gets introduced into the UPDF. The required PDF is provided as input, using the libraries MSTW2008 [40–42] and MMHT2014 [43], where the calculation of the single-scaled functions have been carried out using the DIS data on the \( F_2 \) structure function of the proton. \( T_a \) are considered to be unity for \( k_t > \mu \). This constraint and its interpretation in terms of the strong ordering condition gives the KMR approach a smooth behavior over the small-\( x \) region, which is generally governed by the BFKL evolution equation.

B. The LO MRW framework

In coordination with the theory of gluonic coherent radiation, it has been pointed out that the AOC in the KMR formalism should only act on the terms including the on-shell gluon emissions, i.e. the diagonal splitting functions \( P_{qq}(z) \) and \( P_{gg}(z) \). Therefore, Martin et al defined the LO MRW UPDF as the correction to the KMR framework [6],

\[
f_{q}^{LO}(x, k_t^2, \mu^2) = T_q(k_t^2, \mu^2) \frac{\alpha_S(k_t^2)}{2\pi} \int_x^1 dz \left[ P_{qq}^{(LO)}(z) \frac{x}{z} q \left( \frac{x}{z}, k_t^2 \right) \Theta \left( \frac{\mu}{\mu + k_t} - z \right) \right. \\
\left. + P_{qq}^{(LO)}(z) \frac{x}{z} g \left( \frac{x}{z}, k_t^2 \right) \right],
\]

with

\[
T_q(k_t^2, \mu^2) = \exp \left( -\int_{k_t^2}^{\mu^2} \frac{\alpha_S(k^2)}{2\pi} \frac{dk^2}{k^2} \int_0^{z_{max}} dz' P_{qq}^{(LO)}(z') \right),
\]
for the quarks and
\[ f^{\text{LO}}_g(x, k_t^2, \mu^2) = T_g(k_t^2, \mu^2) \frac{\alpha_S(k_t^2)}{2\pi} \int_x^1 dz P^{\text{LO}}_{gq}(z) \sum_q \frac{x}{z} \delta(\frac{x}{z}, k_t^2) \]
\[ + P^{\text{LO}}_{gg}(z) \frac{x}{z} \delta(\frac{x}{z}, k_t^2) \Theta \left( \frac{\mu}{\mu + k_t} - z \right), \] (9)
with
\[ T_g(k_t^2, \mu^2) = \exp \left( - \int_{k_t^2}^{\mu^2} \frac{\alpha_S(k^2)}{2\pi} \frac{dk^2}{k^2} \left[ \int_{z_{\min}}^{z_{\max}} dz' z' P^{\text{LO}}_{qq}(z') + n_f \int_0^1 dz' P^{\text{LO}}_{gq}(z') \right] \right), \] (10)
for the gluons. In the equations (8) and (10), \( z_{\max} = 1 - z_{\min} = \mu/(\mu + k_t) \) \[46\]. The \textit{UPDF} of \textit{KMR} and \textit{MRW} to a good approximation, include the main kinematical effects involved in the \textit{DIS} processes. One should note that the particular form of the \textit{AOC} in the \textit{KMR} formalism despite being of the \textit{LO}, includes some contributions from the \textit{NLO} sector, whence in the case of \textit{MRW} framework, these contributions must be inserted separately.

C. The \textbf{NLO MRW framework}

The expansions of the \textit{LO MRW} formalism into the \textit{NLO} region can be achieved through the following definitions:
\[ f^{\text{NLO}}_a(x, k_t^2, \mu^2) = \int_x^1 dz T_a \left( k^2 = \frac{k_t^2}{1 - z}, \mu^2 \right) \frac{\alpha_S(k^2)}{2\pi} \sum_{b=q,g} \tilde{P}_{ab}^{(\text{LO}+\text{NLO})}(z) \]
\[ \times b^{\text{NLO}} \left( \frac{x}{z}, k^2 \right) \Theta \left( 1 - z - \frac{k_t^2}{\mu^2} \right), \] (11)
with the \textit{NLO} splitting functions being defined as,
\[ \tilde{P}_{ab}^{(\text{LO}+\text{NLO})}(z) = \tilde{P}_{ab}^{(\text{LO})}(z) + \frac{\alpha_S}{2\pi} \tilde{P}_{ab}^{(\text{NLO})}(z), \] (12)
and
\[ \tilde{P}_{ab}^{(i)}(z) = P_{ab}^{(i)}(z) - \Theta(z - (1 - \Delta))\delta_{ab} F_{ab}^{(i)} P_{ab}(z), \] (13)
where \( i = 0, 1 \) stand for \textit{LO} and \textit{NLO} respectively. The reader can find a comprehensive description of the \textit{NLO} splitting functions in the references \[6, 48\]. We must however emphasis that contrary to the \textit{KMR} and the \textit{LO MRW} frameworks, the \textit{AOC} is being introduced
into the NLO MRW formalism via the $\Theta(z - (1 - \Delta))$ constraint, in the "extended" splitting function. Now $\Delta$ can be defined as:

$$\Delta = \frac{k\sqrt{1 - z}}{k\sqrt{1 - z + \mu}}.$$ 

The NLO corrections introduced into this framework are the collection of the NLO PDF, the NLO splitting functions and the constraint $\Theta(1 - z - k_t^2/\mu^2)$. Nevertheless, it has been shown that using only the LO part of the extended splitting function, instead of the complete definition of equation (12), would result in reasonable accuracy in computation of the NLO MRW UPDF \[6\]. Additionally, the Sudakov form factors in this framework are defined as:

$$T_q(k^2, \mu^2) = \exp \left( -\int_{k^2}^{\mu^2} \frac{\alpha_S(q^2)}{2\pi} \frac{dq_2}{q_2} \int_0^1 dz' z' \left[ \tilde{P}^{(0+1)}_{qq}(z') + \tilde{P}^{(0+1)}_{qg}(z') \right] \right),$$

$$T_g(k^2, \mu^2) = \exp \left( -\int_{k^2}^{\mu^2} \frac{\alpha_S(q^2)}{2\pi} \frac{dq_2}{q_2} \int_0^1 dz' z' \left[ \tilde{P}^{(0+1)}_{gg}(z') + 2n_f \tilde{P}^{(0+1)}_{qg}(z') \right] \right).$$

Each of these UPDF, the KMR, LO and NLO MRW can be used to identify the probability of finding a parton of a given flavor, with the fraction $x$ of longitudinal momentum of the parent hadron, the transverse momentum $k_t$ in the scale $\mu$ at the semi-hard level of a particular DIS process. In the following section, we will describe the cross-section of the production of the $W^\pm$ and $Z^0$ bosons with the help of our UPDF.

### III. PRODUCTION OF $W^\pm$ AND $Z^0$ IN THE $k_t$-FACTORIZATION

By definition, the total cross-section for a deep hadronic collision, $\sigma_{\text{Hadron-Hadron}}$, can be written in terms of its possible partonic constituents. Utilizing the UPDF as density functions for the involved partons, one may write $\sigma_{\text{Hadron-Hadron}}$ in the following form:

$$\sigma_{\text{Hadron-Hadron}} = \sum_{a_1, a_2=q, g} \int_0^1 \frac{dx_1}{x_1} \int_0^1 \frac{dx_2}{x_2} \int_0^\infty \frac{dk_{1,t}^2}{k_{1,t}^2} \int_0^\infty \frac{dk_{2,t}^2}{k_{2,t}^2} f_{a_1}(x_1, k_{1,t}^2, \mu_1^2)f_{a_2}(x_2, k_{2,t}^2, \mu_2^2)$$

$$\times \hat{\sigma}_{a_1a_2}(x_1, k_{1,t}^2, \mu_1^2; x_2, k_{2,t}^2, \mu_2^2),$$

where $a_1$ and $a_2$ are the incoming partons into the semi-hard process from the first and the second hadrons, respectively. $\hat{\sigma}_{a_1a_2}$ are the corresponding partonic cross-sections which can be defined separately as,

$$d\hat{\sigma}_{a_1a_2} = \frac{d\phi_{a_1a_2}}{F_{a_1a_2}} |M_{a_1a_2}|^2.$$  

9
\(d\phi_{a_1a_2}\) and \(F_{a_1a_2}\) are the multi-particle phase space and the flux factor, respectively and can be defined according to the specifications of the partonic process,

\[
d\phi_{a_1a_2} = \prod_i \frac{d^3p_i}{2E_i} \delta^{(4)} \left( \sum p_{in} - \sum p_{out} \right),
\]

\(F_{a_1a_2} = x_1x_2s,\)

with the \(s\) being the center of mass energy squared.

\[s = (P_1 + P_2)^2 = 2P_1.P_2.\]

\(P_1\) and \(P_2\) are the 4-momenta of the incoming protons and since we are working in the infinite momentum frame, it is safe to neglect their masses. \(d\phi_{a_1a_2}\) can be characterized in terms of transverse momenta of the product particles, \(p_{i,t}\), their rapidities, \(y_i\), and the azimuthal angles of the emissions, \(\varphi_i\),

\[
d^3p_i = \frac{\pi}{2} dp_{i,t}^2 dy_i d\varphi_i.
\]

In the equation (17), \(\mathcal{M}_{a_1a_2}\) are the matrix elements of the partonic diagrams which are involved in the production of the final results. To calculate these quantities, one must first understand the exact kinematics that rule over the corresponding partonic processes.

The figure illustrates the ladder-type NLO diagrams that one have to consider, counting the contributions coming from \(g + g \rightarrow W^\pm / Z^0 + q + q'\), \(q + g \rightarrow W^\pm / Z^0 + q' + g\), and \(q + q' \rightarrow W^\pm / Z^0 + g + g\) as shown in the figure panels (a), (b) and (c), respectively. The kinematics and calculations of this type of invariant amplitudes have been discussed extensively in the references [9, 38, 39]. We have followed the same approach, obtaining the \(dk_{i,t}^2/k_{i,t}^2\) terms only from the ladder-type diagrams, and not from the interference (i.e. the non-ladder) diagrams, using a physical gauge for the gluons, where only the two transverse polarizations propagate,

\[d_{\mu\nu}(k) = -g_{\mu\nu} + \frac{k_{\mu}n_{\nu} + n_{\mu}k_{\nu}}{k.n}.\]
would have a numerical effect on the results. Nevertheless, employing the gauge choice \([21]\), one finds out that the contribution from the "unfactorizable" non-ladder diagrams vanishes.

In the proton-antiproton center of mass frame, we can write the following kinematics

\[
P_1 = \frac{\sqrt{s}}{2} (1, 0, 0, 1), \quad P_2 = \frac{\sqrt{s}}{2} (1, 0, 0, -1),
\]

\[
k_i = x_i P_i + k_{i,\perp}, \quad k_{i,\perp}^2 = -k_{i,t}^2, \quad i = 1, 2,
\]

where the \(k_i, i = 1, 2\) are the 4-momenta of the partons that enter the semi-hard process. Afterwards, it is possible to write the law of the transverse momentum conservation for the partonic process:

\[
k_{1,\perp} + k_{2,\perp} = p_{1,\perp} + p_{2,\perp} + p_{\perp},
\]

with \(p_{\perp}\) being the transverse momentum of the produced vector boson. Additionally, defining the transverse mass of the produced virtual partons,

\[
m_{i,t} = \sqrt{m_i^2 + p_{i,t}^2},
\]

we can write,

\[
x_1 = \left(m_{1,t} e^{y_1} + m_{2,t} e^{y_2} + m_{W/Z,t} e^{y_{W/Z}}\right)/\sqrt{s},
\]

\[
x_2 = \left(m_{1,t} e^{-y_1} + m_{2,t} e^{-y_2} + m_{W/Z,t} e^{-y_{W/Z}}\right)/\sqrt{s}.
\]

Now, using the above equations, one can derive the following equation for the total cross-section of the production of the \(W^\pm\) and \(Z^0\) bosons in the framework of \(k_t\)-factorization,

\[
\sigma(P + \bar{P} \rightarrow W^\pm/Z^0 + X) = \sum_{a_1,a_2=q,g} \int \frac{dk_{a_1,t}^2}{k_{a_1,t}^2} \frac{dk_{a_2,t}^2}{k_{a_2,t}^2} dp_{b_1,t} dp_{b_2,t} dy_1 dy_2 dy_{W/Z} \times
\]

\[
\frac{d\varphi_{a_1}}{2\pi} \frac{d\varphi_{a_2}}{2\pi} \frac{d\varphi_{b_1}}{2\pi} \frac{d\varphi_{b_2}}{2\pi} \times
\]

\[
\frac{|\mathcal{M}(a_1 + a_2 \rightarrow W^\pm/Z^0 + b_1 + b_2)|^2}{256\pi^3(x_1 x_2 s)^2} f_{a_1}(x_1, k_{a_1,t}^2, \mu^2) f_{a_2}(x_2, k_{a_2,t}^2, \mu^2).
\]

Note that the integration boundaries for \(dk_{a,t}^2/k_{a,t}^2\) are \((0, \infty)\). One may introduce an upper limit for these, say \(k_{i,\text{max}}\), several times larger than the scale \(\mu\), without any noticeable consequences. Yet, for \(k_t < \mu_0\) with \(\mu_0 = 1 \text{ GeV}\), i.e. for the non-perturbative region, it is impervious to decide how to validate our \text{UPDF}. A natural choice would be to fulfill the requirement that

\[
\lim_{k_{a,t}^2 \rightarrow 0} f_{a_i}(x_i, k_{a,t}^2, \mu^2) \sim k_{a,t}^2,
\]

and therefore, we can safely choose the following approximation for the non-perturbative region:

\[
f_{a_i}(x_i, k_{a,t}^2 < \mu_0^2, \mu^2) = \frac{k_{a,t}^2}{\mu_0^2} \hat{f}_{a_i}(x_i, \mu_0^2) T_{a_i}(\mu_0^2, \mu^2).
\]
In the next section, we will introduce some of the numerical methods that have been used for the calculation of the \( \sigma(P + \bar{P} \to W^\pm/Z^0 + X) \), the equation (25), using the \( UPDF \) of \( KMR \) and \( MRW \). It is expected that through considering \( NLO \) processes for this computation, the results will have a better agreement with the existing experimental data, in comparison with the previous calculations.

IV. NUMERICAL ANALYSIS

The main challenge one must face, in the computations of the total cross-section of a hadron-hadron collision in the \( NLO \), is the extremely complex calculations required for extracting the invariant amplitudes in a set of \( 2 \to 3 \) \( NLO \) Feynman diagrams. Each of our processes, \( g + g \to W^\pm/Z^0 + q + q', q + g \to W^\pm/Z^0 + q' + g, \) and \( q + q' \to W^\pm/Z^0 + g + g, \) include a number of different configurations, see the figure 2. This is when we filter out the non-ladder diagrams, with our choice of the gauge condition on the gluon polarization, the equation (21). Writing the analytic expressions of the \( M_{ab} \) for these diagrams is rather straightforward, see the Appendix A.

However, since the incoming and the out-going quarks are off-shell, and we do not neglect their transverse momenta, their on-shell spin density matrices has to be replaced with a more complicated expression. To do this, one can extend the original expressions, according to an approximation proposed in the references [49, 50], through converting the off-shell quark lines to the internal lines via replacing the spinorial elements of the incoming and the out-going partons. Following this idea, we replace the incoming proton with a quark with the momentum \( p \) and the mass \( m \) which radiates a photon or a gluon and turns into an off-shell quark with the momentum \( k \). Therefore, the corresponding matrix element for such quarks can be written as,

\[
|M|^2 \sim Tr \left( \Gamma_\mu \hat{k} + m \over k^2 - m^2 \gamma^\nu u(p) \bar{u}(p) \gamma_\nu \hat{k} + m \over k^2 - m^2 \Gamma_\mu \right)
\]

where \( \Gamma_\mu \) represents the rest of the original matrix element. Now, the expression presented between \( \Gamma_\mu \) and \( \Gamma^\mu \) is considered to be the off-shell quark spin density matrix. Using the on-shell identity

\[
\sum u(p)\bar{u}(p) = \hat{p} + m,
\]
and after performing some Dirac algebra at the $m \to 0$ limit, one simply arrives to the following expression:

$$|\mathcal{M}|^2 \sim \frac{2}{k^4} Tr \left( \Gamma_\mu \left[ k^2 \hat{p} - 2 (p \cdot k) \hat{k} \right] \Gamma^\mu \right).$$

Afterwards, imposing the Sudakov decomposition $k = xp + k_t$ with $k^2 = k_t^2 = -k_t^2$, one derives:

$$|\mathcal{M}|^2 \sim \frac{2}{x k_t^4} Tr \left( \Gamma_\mu \ x \hat{p} \Gamma^\mu \right). \quad (27)$$

Thus, with the above replacement, the negative light-cone momentum fractions of the incoming partons have been neglected. $x \hat{p}$ in this equation represents the properly normalized off-shell spin density matrix. Additionally, the coupling vertices of the off-shell gluons to quarks must be modified with the eikonal vertex (i.e the BFKL prescription, see the reference $[39]$). Therefore, in the case of initial off-shell gluons, we impose the so-called non-sense polarization condition, i.e.

$$\epsilon_\mu(k_i) = \frac{2k_{i,\mu}}{\sqrt{s}},$$

which results into the following normalization identity

$$\sum \epsilon_\mu(k_i) \epsilon^*_\nu(k_i) = \frac{k_{i,\mu} k_{i,\nu}}{k_{i,t}^2}.$$  

We can calculate the evolution of the traces of the matrix elements with the help of the algebraic manipulation system FORM, $[51]$. Also, the method of orthogonal amplitudes, see the reference $[39]$, can be used to further simplify the results.

The numerical computation of the equation (25) have been carried out using the VEGAS algorithm in the Monte-Carlo integration. To do this, we have selected the hard-scale of the UPDF to be equal to the transverse mass of the produced gauge vector boson:

$$\mu = \left( m_{W/Z}^2 + p_{W/Z,t}^2 \right)^{\frac{1}{2}}.$$  

Mathematically speaking, the upper bound on the transverse momentum integrations of the master equation (25) should be the infinity. However, since the UPDF of KMR and MRW tend to quickly vanish in the $k_t \gg \mu$ domain, one can safely introduce an ultraviolet cut-off for these integrations. By convention, this cut-off is considered to be at $k_{i,max} = p_{i,max} = 4\mu$. Nevertheless, given that $\mu$ depends on the transverse momentum of the produced boson ($p_{W/Z,t}$) and its mass, it would be sufficient to set $k_{i,max} = p_{i,max} = 4\mu_{max}$, with

$$\mu_{max} = \left( m_{W/Z}^2 + p_{t,max}^2 \right)^{\frac{1}{2}}.$$  

13
One can easily confirm that further domain have no contribution into our results. Also it is satisfactory to bound the rapidity integrations to $[-10, 10]$, since $0 \leq x \leq 1$ and according to the equation (24), further domain has no contribution into our results. The choice of above hard scale is reasonable for the production of W and Z bosons, as has been discussed in the reference [39].

As a final note, we should make it clear that in the reference [38], the calculation of the transverse momentum distribution for the production of the W and Z bosons has been carried out, using the aggregated contributions of the following sub-processes:

a) The NLO $g + g \rightarrow W/Z + q + \bar{q}$ partonic process, using the unintegrated gluon distributions of the CCFM and the LO MRW formalisms, accounting for the production of the bosons accompanied by (at least) two distinct jets.

b) The LO $q + g \rightarrow W/Z + \bar{q}$ partonic process, with the density function of the incoming quarks and gluons being defined in the collinear (GRV or MSTW) and the $k_t$-factorization (the CCFM and the LO MRW) formalisms, respectively. This corresponds to the $p + \bar{p} \rightarrow W/Z + jet + X$ cross-section.

c) The LO $q + \bar{q} \rightarrow W/Z$ partonic process, from the collinear approximation, assuming that the incoming particles are valance quarks (or valance anti-quarks).

The above paratonic processes (a, b and c) obviously neglect some of the NLO contributions (in the b and c cases), namely the shares of the non-valance quarks along the chain of evolution. Additionally, assuming the non-zero transverse momentum for the valance quarks in the infinite momentum frame is to some extent unacceptable, since, in the absence of any extra structure, the intrinsic transverse momenta of the valance quarks should not be enough for producing the W/Z bosons with relatively large $p_t$. In the present work, we have upgraded the partonic processes of the b and c cases with their NLO counterparts, i.e. $q^* + g^* \rightarrow W/Z + q + g$ and $q^* + \bar{q}^* \rightarrow W/Z + g + g$ sub-processes. So, we are able to use the UPDF of the $k_t$-factorization for the incoming quarks and gluons to insert the transverse momentum dependency of the produced bosons, and at the same time avoid over-counting. Furthermore, the problem of separating the $W/Z$+single-jet and the $W/Z$+double-jet cross-sections will reduce to inserting the correct physical constraints on the dynamics of these processes, e.g. via inserting some transverse momentum cuts for the produced jets, using the
V. RESULTS, DISCUSSIONS AND CONCLUSIONS

Using the theory and the notions of the previous sections, one can calculate the production rate of the $W^\pm$ and $Z^0$ gauge vector bosons for the center-of-mass energy of 1.8 TeV. The PDF of Martin et al. [40–43], MSTW2008 and MMHT2014, are used as the input functions to feed the equations (6), (7), (9) and (11). The results are the double-scale UPDF in the KMR, the LO MRW and the NLO MRW schemes. These UPDF are in turn substituted into the equation (25) to construct the $W/Z$ cross-sections in their respective frameworks. Since we intend to compare our calculations to the $W^\pm \rightarrow l^\pm + \nu$ and $Z \rightarrow l^+ + l^-$ decays, we should multiply our theoretical output by the relevant branching fractions, i.e. $f(W^\pm \rightarrow l^\pm + \nu) = 0.1075$ and $f(Z \rightarrow l^+ + l^-) = 0.03366$ [53]. Thus, the figures 3 and 4 present the reader, with a comparison between the different contributions into the differential cross-sections of the $W^\pm$ and $Z^0$, versus their transverse momentum ($k_t$) in the KMR scheme. The main contributions into the production of the $W^\pm$ are those involving $u \rightarrow W+d$ and $c \rightarrow W+s$ vertices. Other production vertices have been calculated and proven to be negligible compared to these main contributions (nevertheless, for the sake of completeness, we have included every single share, no matter how small they are in the total contributions, see the figures 5 and 6, where the individual contributions of each of the production vertices in the partonic sub-processes for the production of $W^\pm$ and $Z^0$ have been depicted clearly, in the framework of KMR for $E_{CM} = 1.8$ TeV). In the case of $Z^0$ production, the main vertices are $u \rightarrow Z+u$, $d \rightarrow Z+d$, $c \rightarrow Z+c$ and $s \rightarrow Z+s$. In both cases, one can recognize the different behavior of various partonic sub-processes. As expected, the contributions of the $g+g \rightarrow W/Z+q+\bar{q}$ in all of the diagrams are similar, and even (roughly) of the same size, since they only depend on the behavior of the gluon density. On the other hand, the contribution coming from the $q+\bar{q} \rightarrow W/Z+g+g$ differs from one production vertex to another, mimicking the differences between the quark densities of different flavors and going from the high contributions of the up and down quarks to small contributions of the charm and strange and even negligible contributions of the top anti-$k_t$ algorithm, see the reference [52]. Nevertheless, since we are interested to calculate the inclusive cross-section for the production of the $W/Z$ bosons, inserting such constraints is unnecessary.
and bottom quarks. Additionally, one notices the smallness of the \( q + g \rightarrow W/Z + q' + g \) contributions. This is also anticipated, since the incoming gluon could (with a relatively large probability) decay into a quark-antiquark pair that does not have the right flavor to form a production vertex with considerable contribution.

The figures 7 and 8 illustrate a complete comparison between the results of the calculation of the production of the electro-weak gauge vector bosons in the frameworks of \( KMR \), \( LO \ MRW \) and \( NLO \ MRW \), with each other and with the experimental data of the \( D0 \) and \( CDF \) collaborations, references \[31, 32, 34–37\]. The results in the \( KMR \) framework has an excellent agreement with the experimental data, both in the \( W^\pm \) and \( Z^0 \) productions. The \( LO \ MRW \) scheme behaves similarly compared to the \( KMR \) framework, yet has a noticeably shorter peak, specially in the case of \( Z^0 \). This is due the different visualization of the \( AOC \) between these two frameworks, see the section 3. Meanwhile, the results in the \( NLO \ MRW \) scheme are unexpectedly unable to describe the experiment data. This is related to the conditions in which the \( AOC \) has been imposed in this framework. The \( \theta(1 - z - k^2_t/\mu^2) \) constraint gives the parton distributions of the \( NLO \ MRW \), a sharp descend to zero at \( k_t \rightarrow \mu \) and returns a vanishing contribution for the better part of the transverse momentum integration in the equation (25). Consequently, the overall value of the differential cross-sections of the \( W^\pm \) and \( Z^0 \) production in this framework reduces dramatically, as it is apparent in the figures 7 and 8. In overall and as it has been stated elsewhere (see for example the references \[27, 28\]) the results in the \( KMR \) scheme seemingly have a better agreement with the experiment. This is to some extend ironic, since the \( LO \) and the \( NLO \ MRW \) formalisms are developed as extensions and improvements to the \( KMR \) approach and are more compatible with the \( DGLAP \) evolution equation.

Such comparisons can also be made for the larger values of \( k_t \), see the figures 9 and 10 where the production rates of the electro-weak gauge bosons are plotted against their transverse momentum for \( k_t < 200 \ GeV \). The diagrams include the calculations of \( d\sigma_{W/Z}/dk_t \) and \( 1/\sigma_W \ d\sigma_W/dk_t \) and the comparisons are made with the help of the data from the \( D0 \) collaboration, references \[34, 37\]. Of course, since the data points have small values and large errors, and because of the closeness of the results in different frameworks, one cannot stress over the superiority of any of the approaches. Yet, our previous conclusion about the validity of the \( KMR \) UPDF and the short-comings of the \( NLO \ MRW \) UPDF holds. Another interesting observation is that in the large \( k_t \), where because of the smallness of
the results the higher order corrections become important, the calculations in the KMR approach start to separate from the \(LO\) MRW and behave similar to the NLO MRW. The reason is that the inclusion of the non-diagonal splitting functions into the domain of the AOC introduces some corrections from the NLO region. Additionally, one notices that the contribution coming from the \(q + q' \to W^\pm + g + g\) in the NLO evaluations considerably deviates from the similar behavior of its respective counterparts. This of course roots in the evolution of the NLO quark densities in this framework, see the reference [46].

Recently, Martin et al have updated their PDF libraries, the reference [43]. The figures [11] and [12] demonstrate the differences between the cross-section of the production of the \(W/Z\) vector bosons in the KMR framework, using the (older) MSTW2008 and the (newer) MMHT2014 PDF. One notices that, using either of these PDF as input for our UPDF produces a negligible difference.

The figures [13] and [14] present an interesting comparison between the experimental data and the results of the different approximations in the calculation of the production of the electro-weak gauge vector bosons. In addition to our calculations in the KMR and the MRW UPDF in the LO and the NLO approximations, the results coming from the CCFM TMD PDF (reference [38]), the doubly unintegrated parton distributions (DUPDF, see the reference [9]) and from the collinear frameworks are included in these diagrams. The CCFM results are calculated as the sum of \(g + g \to W/Z + q + q'\), \(g + q \to W/Z + q'\) and \(q + q \to W/Z\) sub-processes. The DUPDF results are in the \((k_t - z)\)-factorization framework, utilizing a \(q + q \to W/Z\) "effective" production vertex. Furthermore, to calculate the differential cross-section of the \(W/Z\) production in the collinear approximation, one have to ignore the transverse momentum integrations in the equation (25) and replace the UPDF with the unpolarized parton distributions of MSTW2008, MMHT2014 or GRV2009 [54–56]:

\[
\sigma(P + \bar{P} \to W^\pm/Z^0 + X) = \sum_{a_1,b_1=q,g} \int dp_{b_1,t}^2 dp_{b_2,t}^2 dy_{W/Z} dy_{W/Z} \frac{d\varphi_{b_1}}{2\pi} \frac{d\varphi_{b_2}}{2\pi} \times \\
\frac{|\mathcal{M}(a_1 + a_2 \to W/Z + b_1 + b_2)|^2}{256\pi^3(x_1x_2s)^2} \ a_1(x_1,\mu^2) \ a_2(x_2,\mu^2). \tag{28}
\]

The reader should notice that the results of our computations in the NLO regime, as expected, have a better behavior towards describing the experimental data, both in the \(W^\pm\) and \(Z^0\) cases, since they descend with a shallow steep, compared to the results calculated in
other schemes. This is in part, because the \textit{NLO} evaluations are inherently more accurate. Yet, most of the credit goes to the precision of the utilized \textit{UPDF}. Again, the \textit{KMR} framework in the \textit{NLO} calculations offers the best description of the experiment.

Additionally, it is possible to compare our presumed frameworks through the calculation of the total cross-section of the $W^\pm$ and $Z^0$ production with respect to the center-of-mass energy of the hadronic collision, i.e. the figures \ref{fig:15} and \ref{fig:16}. Following our previous pattern, the results of both the \textit{KMR} and the \textit{LO MRW} frameworks show a good level of compatibility with the experimental data. On the other hand, since the \textit{NLO MRW} framework has failed to describe the data, we have excluded its contributions here, to save some computation time.

Finally, it has been brought to our attention that the \textit{ATLAS} and \textit{CMS} collaborations have recently published some data regarding the production of the $Z^0$ gauge vector boson in the \textit{LHC} for $E_{CM} = 8$ TeV, the references \cite{57,58}. In the above calculations, the rapidity of the produced boson has been separated in equally spaced rapidity sectors within $0 < |y_Z| < 2.4$ domain. In figure \ref{fig:17}, we have addressed the above observations, using our \textit{NLO} framework and utilizing the \textit{UPDF} of \textit{KMR}, since we have already established the superiority of this scheme in describing the experiment. The individual contributions from the partonic sub-processes are presented and the total values of (single and double) differential cross-sections are subjected to comparison with the data of the \textit{ATLAS} and \textit{CMS} collaborations. One easily notes that our calculations is in general agreement with the experimental data and with similar calculations in a \textit{NNLO QCD} framework from the reference \cite{59}.

Unfortunately, performing these calculations are extremely time-consuming and the existing data points are not plentiful or accurate enough to let us make a decisive statement about the superiority regarding any of our presumed frameworks. Nevertheless, considering these comparisons, it is apparent that the \textit{KMRUPDF} in the framework of $k_t$-factorization, despite their miss-alignments with the theory of the \textit{DGLAP} evolution equation and the physics of the successive gluon radiations, as an effective theory, proposes the best option to describe the deep inelastic \textit{QCD} events. However, until further phenomenological analysis, such claim remains as an educated speculation.

In summary, within the present work, we have calculated the rate of productions belonging to the electro-weak gauge vector bosons in the framework of $k_t$-factorization, utilizing the
UPDF of KMR, LO MRW and NLO MRW, by the means of NLO QCD processes. The results have been demonstrated and compared to each other and to the experimental data points from the D0 and the CDF collaborations, as well as the calculations in other frameworks. Through our analysis we have suggested that despite the theoretical advantages of the MRW formalism, the KMR approach has a better behavior toward describing the experiment.

Acknowledgments

MM would like to acknowledge the Research Council of University of Tehran and the Institute for Research and Planning in Higher Education for the grants provided for him.

MRM sincerely thanks A. Lipatov and N. Darvishi for their valuable discussions and comments. MRM extends his gratitude towards his kind hosts at the Institute of Nuclear Physics, Polish Academy of Science for their hospitality during his visit. He also acknowledges the Ministry of Science, Research and Technology of Iran that funded his visit.

Appendix A: The matrix elements of the partonic sub-processes

Given that we are interested in the calculation of the matrix element squared for each process, one immediately concludes that the $|\mathcal{M}^{gg}|^2 = |\mathcal{M}^{qq}|^2$. Therefore it is sufficient to calculate the invariant amplitudes for the Feynman diagrams of the figure 2, the panels (b) and (c), which can be written as follows:

$$\mathcal{M}^{ab} = \sum_{i=1}^{8} \mathcal{M}_{i}^{ab}, \quad a, b = q, g,$$  \hspace{1cm} \text{(A1)}

with

$$\mathcal{M}_{1}^{gg} = g_8^2 \ u(k_1) \ t^a \gamma_\mu \epsilon^\mu(p_1) \ \frac{(k_1 - p_1) + m}{(k_1 - p_1)^2 - m^2} \ G_{W,Z}^\lambda \epsilon_\lambda(p_3)$$

$$\frac{(k_2 + p_2) + m}{(k_2 + p_2)^2 - m^2} \ t^b \gamma_\nu \epsilon^\nu(k_2) \ \bar{u}(p_2),$$  \hspace{1cm} \text{(A2)}

$$\mathcal{M}_{2}^{gg} = g_8^2 \ u(k_1) \ t^b \gamma_\mu \epsilon^\nu(k_2) \ \frac{(k_1 + k_2) + m}{(k_1 + k_2)^2 - m^2} \ G_{W,Z}^\lambda \epsilon_\lambda(p_3)$$

$$\frac{(k_2 + k_2 - p_3) + m}{(k_2 + k_2 - p_3)^2 - m^2} \ t^a \gamma_\mu \epsilon^\mu(p_1) \ \bar{u}(p_2),$$  \hspace{1cm} \text{(A3)}
\[ \mathcal{M}^{gg}_3 = 2g_s^2 u(k_1) t^a \gamma_\mu \epsilon^\mu(p_1) \frac{(k_1 - p_1) + m}{(k_1 - p_1)^2 - m^2} \]
\[ t^b \gamma_\nu \epsilon^\nu(p_2) \frac{(p_2 + p_3) + m}{(p_2 + p_3)^2 - m^2} G^\lambda_{W,Z} \epsilon^\lambda(p_3) \bar{u}(p_2), \]  
(A4)
\[ \mathcal{M}^{gg}_4 = 2g_s^2 u(k_1) t^a \gamma_\mu \epsilon^\mu(k_2) \frac{(k_1 + k_2) + m}{(k_1 + k_2)^2 - m^2} \]
\[ t^b \gamma_\nu \epsilon^\nu(p_1) \frac{(k_1 + k_2 - p_1) + m}{(k_1 + k_2 - p_1)^2 - m^2} G^\lambda_{W,Z} \epsilon^\lambda(p_3) \bar{u}(p_2), \]  
(A5)
\[ \mathcal{M}^{gg}_5 = g_s^2 u(k_1) \gamma^\rho C^{\mu \nu \rho}(k_2, -p_1, p_1 - k_2) \epsilon^{\mu \nu}(p_2) \frac{f^{abc} \epsilon^c}{(k_2 - p_1)^2} \]
\[ \frac{(p_2 + p_3) + m}{(p_2 + p_3)^2 - m^2} G^\lambda_{W,Z} \epsilon^\lambda(p_3) \bar{u}(p_2), \]  
(A6)
\[ \mathcal{M}^{gg}_6 = g_s^2 u(k_1) G^{\lambda}_{W,Z} \epsilon^\lambda(p_3) \frac{(k_1 - p_3) + m}{(k_1 - p_3)^2 - m^2} \]
\[ \gamma^\rho C^{\mu \nu \rho}(k_2, -p_1, p_1 - k_2) \epsilon^{\mu \nu}(p_2) \frac{f^{abc} \epsilon^c}{(k_2 - p_1)^2} \bar{u}(p_2), \]  
(A7)
and
\[ \mathcal{M}^{gg}_1 = g_s^2 \bar{u}(p_1) t^a \gamma_\mu \epsilon^\mu(k_1) \frac{(p_1 - k_1) + m}{(p_1 - k_1)^2 - m^2} G^\lambda_{W,Z} \epsilon^\lambda(p_3) \]
\[ \frac{(p_2 + k_2) + m}{(p_2 + k_2)^2 - m^2} t^b \gamma_\nu \epsilon^\nu(k_2) u(p_2), \]  
(A8)
\[ \mathcal{M}^{gg}_2 = g_s^2 \bar{u}(p_1) t^a \gamma_\mu \epsilon^\mu(k_1) \frac{(k_2 - p_1) + m}{(k_2 - p_1)^2 - m^2} G^\lambda_{W,Z} \epsilon^\lambda(p_3) \]
\[ \frac{(k_1 + p_2) + m}{(k_1 + p_2)^2 - m^2} t^b \gamma_\nu \epsilon^\nu(k_2) u(p_2), \]  
(A9)
\[ \mathcal{M}^{gg}_3 = g_s^2 \bar{u}(p_1) \frac{(p_1 + p_3) + m}{(p_1 + p_3)^2 - m^2} t^a \gamma_\mu \epsilon^\mu(k_1) \]
\[ \frac{(p_1 + p_3 - k_1) + m}{(p_1 + p_3 - k_1)^2 - m^2} G^\lambda_{W,Z} \epsilon^\lambda(p_3) t^b \gamma_\nu \epsilon^\nu(k_2) u(p_2), \]  
(A10)
\[ \mathcal{M}^{gg}_4 = g_s^2 \bar{u}(p_1) G^\lambda_{W,Z} \epsilon^\lambda(p_3) t^a \gamma_\mu \epsilon^\mu(k_1) \frac{(p_1 - k_1) + m}{(p_1 - k_1)^2 - m^2} \]
\[ t^b \gamma_\nu \epsilon^\nu(k_2) \frac{(p_1 - k_1 - k_2) + m}{(p_1 - k_1 - k_2)^2 - m^2} u(p_2), \]  
(A11)
\[ \mathcal{M}^{gg}_5 = g_s^2 \bar{u}(p_1) G^\lambda_{W,Z} \epsilon^\lambda(p_3) \frac{(p_1 + p_3) + m}{(p_1 + p_3)^2 - m^2} t^b \gamma_\nu \epsilon^\nu(k_2) \]
\[ \frac{(p_1 + p_3 - k_2) + m}{(p_1 + p_3 - k_2)^2 - m^2} t^a \gamma_\mu \epsilon^\mu(k_1) u(p_2), \]  
(A12)
\[ \mathcal{M}^{gg}_6 = g_s^2 \bar{u}(p_1) G^\lambda_{W,Z} \epsilon^\lambda(p_3) t^b \gamma_\nu \epsilon^\nu(k_2) \frac{(p_1 - k_2) + m}{(p_1 - k_2)^2 - m^2} \]
\[
M_{7g}^{gg} = g_s^2 \bar{u}(p_1) \gamma^\rho C^{\mu \nu \rho}(k_1, k_2, -k_1 - k_2) \frac{\epsilon_{\mu \nu}}{(k_1 + k_2)^2} f^{abc} \epsilon^c \\
\frac{(p_1 - k_1 - k_2) + m}{(p_1 - k_1 - k_2)^2 - m^2} G_{W,Z}^\lambda (p_3) u(p_2),
\]
\[
M_{8g}^{gg} = g_s^2 \bar{u}(p_1) G_{W,Z}^\lambda (p_3) \frac{(p_1 - p_3) + m}{(p_1 - p_3)^2 - m^2} \\
\gamma^\mu C^{\mu \nu \rho}(k_1, k_2, -k_1 - k_2) \frac{\epsilon_{\mu \nu}}{(k_1 + k_2)^2} f^{abc} \epsilon^c u(p_2),
\]

where \( g_s \) is the running coupling constant for QCD and \( G_{W,Z}^\lambda \) represents the vertex of the electro-weak gauge vector bosons with quarks:

\[
G_W^\lambda = \frac{e_{em}}{2\sqrt{2} \sin \theta_w} \gamma^\lambda (1 - \gamma^5) V_{qq'}
\]

\[
G_Z^\lambda = \frac{e_{em}}{\sin 2\theta_w} \gamma^\lambda \left[ I_{3,q}(1 - \gamma^5) - 2e_q \sin^2 \theta_w \right].
\]

\( \theta_w \) is the Weinberg angle, \( V_{qq'} \) is the corresponding CKM matrix element and \( I_{3,q} \) is the weak isospin component of the quark \( q \). Additionally, the standard QCD three-gluon coupling can be written as follows:

\[
C^{\mu \nu \rho}(k_1, k_2, k_3) = g^{\mu \nu}(k_2 - k_1)^\rho + g^{\nu \rho}(k_3 - k_2)^\mu + g^{\rho \mu}(k_1 - k_3)^\nu.
\]

With the above information, one has enough tools to calculate the matrix elements of the equation (25).

FIG. 1: The NLO ladder-type diagrams for the production of $W^\pm$ and $Z^0$ in the $k_t$-factorization framework. The $f_g(x, k_t^2, \mu^2)$ and $f_q(x, k_t^2, \mu^2)$ represent the corresponding UPDF in the KMR, the LO-MRW or the NLO-MRW frameworks, i.e. the equations (6), (7), (9) and (11).

FIG. 2: The individual contributions into the matrix elements of the partonic scattering. The diagrams in the panel (a) correspond to the $q + \bar{q}' \rightarrow W^\pm/Z^0 + g + g$ sub-process, panel (b) to the $q + g \rightarrow W^\pm/Z^0 + q + g$ sub-process and panel (c) to the $g + g \rightarrow W^\pm/Z^0 + q + \bar{q}'$ sub-process. It should be pointed out that one may find additional non-ladder-type diagrams which contribute to these matrix elements. We have eliminated these un-desirable contributions using our choice of the gluon gauge, the equation (21).
FIG. 3: The differential cross-section of the productions of $W^\pm$ bosons in a DIS at $E_{CM} = 1.8$ TeV, against the transverse momentum distribution of the produced particle. The panels (a) and (b) illustrate the up-down and charm-strange contributions, respectively. The contribution of each partonic sub-process is singled out: the green-dash histogram is for $g + g \rightarrow W^\pm + q + \bar{q}'$, the red-dotted histogram is for $q + g \rightarrow W^\pm + q' + g$ and the blue-dash-dotted histogram is for $q + \bar{q}' \rightarrow W^\pm + g + g$. The black-full histogram is the total contribution of the give quark pairs. The histograms are produced using the $KMR\ UPDF$ with the $PDF$ of $MSTW2008$. 
FIG. 4: The differential cross-section of the productions of $Z^0$ boson in a DIS at $E_{CM} = 1.8 \, TeV$, against the transverse momentum distribution of the produced particle. The contributions of the up and the down quarks (the panels (a) and (b), respectively) and the lightest sea-quarks (the panel (c) for the charm quark and the panel (d) for the strange quark). The green-dash histogram is for $g+g \rightarrow Z^0+q+\bar{q}$, the red-dotted histogram is for $q+g \rightarrow Z^0+q+g$ and the blue-dash-dotted histogram is for $q+\bar{q} \rightarrow Z^0+g+g$. The black-full histogram is the total contribution of the given quark. The data is produced using the $KMR \, UPDF$, with the $PDF$ of $MSTW2008$. 
FIG. 5: The contributions of the individual partonic sub-processes into the differential cross-section of the productions of $W^\pm$ bosons in a DIS at $E_{CM} = 1.8$ TeV, versus the transverse momentum distribution of the produced particle. The panels (a), (b) and (c) correspond to the $g + g \rightarrow W^\pm + q + \bar{q}'$, $q + \bar{q}' \rightarrow W^\pm + g + g$ and $g + q \rightarrow W^\pm + g + q'$ sub-processes, respectively. The data have been obtained using the $UPDF$ of KMR, with the $PDF$ of MSTW2008.

FIG. 6: The contributions of the individual partonic sub-processes into the differential cross-section of the productions of $Z^0$ bosons in a DIS at $E_{CM} = 1.8$ TeV, versus the transverse momentum distribution of the produced particle. The notions of the diagrams are the same as in the figure 5.
FIG. 7: The comparison of the differential cross-section of the $W^\pm$ production in the $NLO$ in the $KMR$ (the panel (a)), $LO$ $MRW$ (the panel (b)) and $NLO$ $MRW$ (the panel (c)) frameworks. The panel (d) illustrates this comparison with the help of experimental data of $D0$ collaboration, the reference [37]. The panels (e),(f) and (g) are the same values, but this time they deviled by the total cross-sections in their respective framework and compared to an older set of data points from the $D0$ collaboration, [34]. Again, an overall comparison with the experiment is presented in the panel (h). To perform these calculations, we have utilized the $PDF$ of $MSTW2008$. 
FIG. 8: The comparison of the differential cross-section of the $Z^0$ production in the NLO in the KMR (the panel (a)), LO MRW (the panel (b)) and NLO MRW (the panel (c)) frameworks. The panel (d) illustrates this comparison with the help of the experimental data of D0 and CDF collaborations, the references [32, 34].
FIG. 9: The production rate of the $W^\pm$ boson in $E_{CM} = 1.8$ TeV. The labels (a), (b) and (c) compare the contributions of the individual sub-processes in their respective frameworks. The total values of differential cross-section in these frameworks are subjected to a comparison with the data of the $D0$ collaboration [37] separately, in the label (d). This very same notion is also presented in the labels (e) through (f), where the $1/\sigma \, d\sigma / dkt$ histograms are being compared with each other and with the data from [34].
FIG. 10: The production rate of the $Z^0$ boson in $E_{CM} = 1.8 \, TeV$. The notions of the diagrams are the same as in the Fig. 9.

FIG. 11: Comparison of the differential cross-section of the $W^\pm$ production, using the $UPDF$ of $KMR$, prepared with the $PDF$ of $MSTW2008$ (label (a)) and $MMHT2014$ (label (b)). label (c) shows their difference relative to the experimental data of the $D0$ collaboration, reference 37.
FIG. 12: Comparison of the differential cross-section of the $Z^0$ production, using the UPDF of KMR, prepared with the PDF of MSTW2008 (label (a)) and MMHT2014 (label (b)). label (c) shows their difference relative to the experimental data of the D0 and CDF collaborations, references [32, 34].

FIG. 13: The differential cross-section of the production of the $W^\pm$, calculated in different frameworks, against the transverse momentum of the produced gauge boson at $E_{CM} = 1.8 TeV$. The notions of the histograms are as follows: the continues black histogram represents the calculation in using the KMR UPDF, the dotted green histogram is prepared in LO MRW framework and the short-dotted red in the NLO MRW. To perform these calculations, we have utilized the PDF of MSTW2008. the brown dot-dot-dashed histogram in produced using the CCFM TMD PDF (reference [38]). The yellow dotted-dashed histogram is calculated, utilizing the doubly unintegrated parton distributions (DUPDF) in the framework of $(k_t-z)$-factorization, reference [9]. The purple short-dashed histogram is calculated in the collinear framework.
FIG. 14: The differential cross-section of the production of the $Z^0$, calculated in different frameworks, against the transverse momentum of the produced gauge boson at $E_{CM} = 1.8$ TeV. The notions of the histograms are the same as in Fig. 13.

FIG. 15: The cross-section of the production of the $W^\pm$ bosons as a function of the center-of-mass energy, $E_{CM}$. The experimental data are acquired from the $UA1$, $UA2$, $D0$ and $CDF$ collaborations, references [29, 37]. The calculations are performed using the $KMR$ and the $LO MRW UPDF$. We have omitted the $NLO UPDF$ results here, to save computation data.

FIG. 16: The cross-section of the production of the $Z^0$ bosons as a function of the center-of-mass energy, $E_{CM}$. The notation of the diagram is the same as in the figure 15.
FIG. 17: Production of the $Z^0$ boson in $E_{CM} = 8$ TeV, using the KMR approach. The individual contributions from the partonic sub-processes are presented and the total values of (single and double) differential cross-sections are subjected to comparison with the data of the ATLAS (black circles) and CMS (white circles) collaborations $^{57,58}$. The labels (a) through (f) illustrate the results of our calculations for single differential cross-section of the production of $Z^0$, in the given rapidity regions. The results for double differential cross-section are presented in the this figure with labels (g) through (h).
