ABSTRACT: There has been recent progress towards understanding the dynamics of world-volume fermions that arise as open-string modes from brane intersections in the probe limit ($N_f/N_c \to 0$). In this work we consider all possible BPS brane junctions in Type IIA/B supergravity theories. We study in detail the dynamics of these states by deriving their equations of motion. We show the expected degeneracy of the bosonic and fermionic fluctuations as is expected due to the preserved supersymmetry. We also give some supporting evidence and refine the notion that these states can effectively describe baryon operators in a certain regime of the field theory’s parameter space. Our piece of evidence is the demonstration of the expected scaling of the mass in the large-$N_c$ limit of the theory for these fermionic states; $M^2 \sim N_c^2$. Finally, we explain analytically the avoided level crossing that was observed in a previous work after the inclusion of higher dimension operators in the field theory.

ArXiv ePrint: 2010.00025
1 Prologue

The AdS/CFT correspondence [1–3] asserts that certain field theories are dual (equivalent) to string theory in an AdS space. The original proposal was generalized shortly after its discovery to a more general notion of gauge/gravity dual pairs in various dimensions, by considering different Dp-branes [4]. The prescription is, tersely, to consider a stack of \( N_c \) Dp-branes that coincide and take the limit in which the brane modes decouple from the bulk. We are left with a super Yang-Mills (SYM) theory with a \( U(N_c) \) gauge group on the \((p + 1)\)-dimensional worldvolume of the Dp branes. This SYM theory is dual to string
theory in the near-horizon limit of the background induced by the stack of Dp-branes. For any Dp-brane with $p \neq 3$, the holographic gauge description is a non-conformal theory, since the Yang-Mills coupling carries dimensions. The energy scale of the gauge theory is mapped to the radial coordinate in the gravity side which is orthogonal to the branes. The absence of conformal invariance manifests itself in the bulk by the non-trivial radial profile of the dilaton as well as the spacetime curvature. The supergravity approximation holds when the string coupling is weak and the curvature small. It gives a theory which is trustworthy for an intermediate regime of energies, where the dual gauge theory is always strongly coupled. For the case $p = 3$, the supergravity description is valid for all energy regimes as the dilaton is just a constant. A classic review of the AdS/CFT with a detailed exposition to the above as well as other basic ideas is [5].

In its original form, the AdS/CFT relates Type IIB string theory in $AdS_5 \times S^5$ to the four-dimensional $\mathcal{N} = 4$ SYM. All matter fields transform in the adjoint representation of the gauge group. For the supergravity descriptions of confining gauge theories [6], it is possible to calculate the spectra of glueball states by considering the corresponding spectra of supergravity modes such that the classical solutions to equations of motion are normalisable. There is extensive work on glueball spectra and we cannot do justice to the literature so we mention indicatively some of the main papers [7–10].

One of the main questions that the community tried to understand since the early days of the duality was how to add fields that transform in the fundamental representation of the gauge group, such that the duality contains matter in appropriate group representations, and thus taking the duality a step closer to the more interesting quantum field theories and thus making the correspondence more physical and appealing. An early variant of the AdS/CFT describing a field theory with matter in the fundamental representation related the conformal $Sp(2N_c)$ with $\mathcal{N} = 2$ theory to D3-branes near singularities in F-theory; string theory in $AdS_5 \times S^5/\mathbb{Z}_2$ [11–13].

In a landmark paper [14], Karch and Katz showed that adding D7 branes in the probe limit — such that the D-branes do not backreact to the background geometry — is the appropriate way to add matter fields transforming the fundamental representation of the gauge group in the original setup with the D3-branes that generate the $AdS_5 \times S^5$ background. The addition of $N_f$ D7 branes in the $AdS_5 \times S^5$ background is equivalent to coupling $N_f$ hypermultiplets in the fundamental representation of the original SYM theory. The probe (or in the field theory language the quench) limit corresponds to having $N_f/N_c \rightarrow 0$. The stretched strings between the two different branes are the fields that we consider as dynamical quarks, specifically the lightest string states that stretch between the two different types of branes. Adding the D7 branes reduces the supercharges by half compared to the original setup and the resulting four-dimensional $\mathcal{N} = 2$ theory has quark-antiquark bound states (mesons) and in the decoupling limit the exercise of studying the dynamics and the masses of these states is equivalent to computing the classical equations of motion of open strings. The seminal paper exploring these ideas is [15] where the analysis was performed for the D3-probe D7 system.

A number of directions have been undertaken in order to construct gravity dual descriptions of QCD-like theories. Chiral symmetry breaking has been described in [16–19]
and the meson spectra of brane intersections with eight supercharges have been computed in [20, 21]. For more details on flavour physics and mesons in the context of the gauge/gravity duality see the review [22]. The aforementioned works are all in the probe (in gravity terms) or the quench limit (in the field theory language) of the correspondence such that the branes do not backreact to the geometry. Considerable efforts have been made beyond this approximation. For an excellent review on unquenched flavours in the AdS/CFT see [23].

While much effort has been put and progress has been made towards the understanding of the bosonic sectors of adjoint matter fields comprised out of the fundamental quarks (meson fields), much less attention has been given to their supersymmetric partners. There are some reasons for this.

To begin with, in cases with any amount of supersymmetry the spectra of fermionic states can be derived using representation theory. This counting had been performed in [15] for the fermionic superpartners of the bosonic meson states in the D3/probe-D7 setup. It is worthwhile mentioning that while it is possible to obtain the mass spectra precisely due to the preserved amount of supersymmetry, if one follows this approach then there is no access to the dynamics of world-volume fermions as the equations of motion are missing.

In addition to that, these fermionic superpartners should be formally interpreted as fermionic meson states in the sense they are fermionic fields in the adjoint representation of the $\mathcal{N} = 2$. Such a state has no counterpart neither in the real-world QCD theory nor in any non-supersymmetric version of QCD-like theories. In other words, it can be characterized as a purely supersymmetric effect.

A final hindrance was the form of the fermionic completion to the DBI action. Before the work of [24–26] that particular part of the action was written in superspace [27, 28]. In spite of the compact form of the action and the elegance of the superspace techniques, using the superspace as the target space of the theory obscures how the background fields enter the fermionic terms of the action. Hence, with that particular formulation of the action at our disposal any explicit computations or considerations involving the world-volume fermions cannot be performed. The work of [24–26] resolved precisely that issue and presented an action for world-volume fermions written in terms of the spacetime.

Since the technology developed enough and made explicit computations involving world-volume fermions possible the first explicit results in probe-brane holography started appearing. This was initiated in [29] where the author considered the D3/probe-D7 intersection in the limit where the flavour branes have collapsed on the background ones. In field theory terms, this corresponds to massless quarks. From that effective bottom-up approach a replacement rule was invoked at the level of the equations of motion that yields the correct mass spectra even for the case of the massive embedding of the flavour brane. A follow-up to that work was presented in [30] where the authors followed the same line of reasoning but for all possible probe-brane setups in the D3 background. Another very interesting result was derived in [31], where the authors obtained the spectrum of bosonic and fermionic excitations of 1/2-BPS Wilson loops for a D3-brane in the AdS$_5 \times S^5$ background.

With a formal understanding of the massive embedding in the D3/probe-D7 intersection being a motivation as well as some phenomenological applications of holography and
the use of fermions in bottom-up models, the authors in [32] studied the top-down massive picture in all probe brane systems in the presence of the D3 background and obtained the expressions for the supergravity states dual to these fermions and the corresponding mass spectra. The work of [33] is also a top-down approach that investigates the D4-D8 setup in Type IIA supergravity and it pertains to the Sakai-Sugimoto model [18]. It is worthwhile pointing out that the authors in [32, 33] are using different approaches to finding the mass eigenvalues. In [32] the authors also considered the effect of adding multi-trace operators to these fermionic states following Witten’s prescription [34]. After a careful numerical analysis they observed an avoided level-crossing as one approaches from a higher excited state the lower one in the KK tower.

Another point made by the authors in that paper was that, after analysing the holographic dictionary, they observed that some of the aforementioned fermionic states are made of three elementary Fermi fields; two fields transforming in the fundamental representation (quarks) and one in the adjoint of the gauge group (a gaugino). Hence, the observation that the lowest lying state of that particular supermultiplet resembles qualitatively — by means of the same structure — the baryon operators in real-life QCD.

In this work we continue in a natural line of the aforementioned research and we study all possible probe-branes intersections in Type IIA/B supergravity theories that have been shown to preserve eight supercharges; \( \mathcal{N} = 2 \) SUSY in a four-dimensional language. Since the bosonic mass spectra are explicitly known in these cases [20, 21] the interest lies in the deeper understanding of the dynamics of fermionic open-string states and unveiling potential computational subtleties in the derivation that did not appear in the study of probe-branes in the presence of the D3-background. We obtain the equations of motion explicitly for each case starting from the fermionic action as was derived in [24–26].

We show the expected supersymmetric degeneracy for the mass eigenvalues. For the case of the D3-background there are analytic solutions that have been previously obtained [32] and we report these here for completeness. All the other backgrounds do not admit analytic solutions for the eigenstates of the equations of motion and the mass eigenvalues. For these cases we work in two different ways. To begin with, we perform a careful numerical analysis and obtain the mass eigenvalues directly from the fermionic equations of motion. We see that in each case they are the same as the corresponding results anticipated from the analysis of the bosonic meson states and their equations of motion.

Furthermore, we were able to derive a map such that we bring the equations of motion describing world-volume fermions in our brane intersections to the relevant equations of motion describing bosonic degrees of freedom in these setups. Here some comments are in order. Due to the two eigenvalues of the spinor spherical harmonics we have two sets of supergravity fields. We denote those associated with the positive eigenvalues by \( \mathcal{G} \). These are the superpartners of the gauge fields on the probe-brane which have a non-trivial profile only on the internal manifold. More explicitly, these gauge fields are decomposed as \( A_\mu = 0, \ A_\rho = 0, \ A_i = a(\rho) e^{i k^\mu x_\mu} Y_\ell^i \). From the negative eigenvalue of the spinor spherical harmonic we obtain modes which we generically denote by \( \mathcal{F} \) and they are the superpartners of the scalar fields obtained as fluctuations of the transverse coordinates.
For both types of the fermionic modes described above we were able to map the equations of motion associated with the positive eigenvalue of the projection \( \Gamma \)-matrix defined along the holographic radial coordinate \( (\Gamma^\rho \Psi^\pm = \pm \Psi^\pm) \) to the associated bosonic equations of motion. The map is given by

\[
\psi_{\oplus}^{\psi} (\varrho) = \frac{1}{(1 + \varrho^2)^{\frac{7-p}{4}} f_{\ell+1}(\varrho)}, \quad \psi_{\oplus}^{\phi} (\varrho) = \frac{1}{(1 + \varrho^2)^{\frac{7-p}{4}} f_{\ell}(\varrho)},
\]

where in the above we denote by \( \oplus \) superscript the supergravity modes obtained by considering the projection \( \Gamma^\rho \Psi^\oplus = \Psi^\oplus \) and we reserve the \( \ominus \) for the negative eigenvalue of the projection.

While at this point the reader might be concerned that we were able to map only the equations of motion related to one of the \( \Gamma^\rho \) eigenvalues, there is nothing out of place in doing so. We are able to deduce the eigenstates and mass eigenvalues from either of the equations of motion. The reasoning behind this is simple: we start with two coupled first-order equations of motion that describe a source and the relevant operator. Then, we derive the second-order equations of motion starting from the first-order ones. In doing so we act with an appropriately chosen differential operator and we create a double-copy of the operator and the source [32, 35]. Hence, the equations of each eigenvalue of the \( \Gamma^\rho \) matrix contains a copy of the source and a copy of the operator. By requiring normalizable open-string modes in the UV in either of the equations we are setting the source to zero and hence each second-order differential equation yields the correct answer individually. This procedure is made more precise and explained thoroughly in section 3. We also, further support and refine the argument that these states describe effectively baryons as we show that in large-\( N_c \) limit their mass scales as

\[
M^2 \sim N_c^2,
\]

when we fix the quantum number \( n \) which counts the nodes of the state and the angular quantum number \( \ell \). This scaling in large-\( N_c \) limit of the theory is a purely field theory expectation [36]. The results described by eqs. (1.1) and (1.2) constitute the two main points of this work. The third main result is the explanation of the avoided level crossing, which is explained in section 7.3.

Furthermore, the authors of [32] observed an avoided level crossing when examining the inclusion of multi-trace interactions without giving an analytic explanation for the effect. We revisit that computation and give an analytic justification to the observed avoided level crossing by bringing the equations of motion in a Schrödinger form and examining the solutions of the supergravity modes. Interestingly, such a crossing has been shown to occur when considering instanton configurations in the probe-brane setup [37].

At this point, we would like to clarify that we do not claim that we have solved the true string baryonic vertex. In the large-\( N_c \) limit a baryon is made of \( N_c \) fundamental fields (quarks) and has to be appropriately described in the gravity side. The description is well known [38]. Witten has shown that in the base \( \mathcal{N} = 4 \) SYM theory a baryonic vertex is obtained by a wrapped D5-brane over the \( S^5 \). Since we have not considered the addition of the five-branes in our basic D3/probe-D7 model, we do not approach baryons directly.
in this work. However, we believe that the spectrum we obtain in section 7.2 should be obtained from the full string construction in the limit where the boundary gauge theory is in the conformal window. This result was obtained in an effective, bottom-up way in [29], however a 10-dimensional derivation was lacking, which we provide here.

This is a long and technical paper which we organized in such a way to help the reader navigate more easily through the different sections. The structure of the paper is as follows: in section 2 we present the geometries that are related to our studies and compute some necessary quantities for our computations. We devote a separate section for each supergravity background. The D0-background is analysed very thoroughly in section 3 and it serves as a specific example which we use to demonstrate the general steps of our analysis. After this, we recap the steps necessary and explain the general procedure we are following in section 4. Then, section 5 is devoted to the D1 solution of IIB. The case of the D2-background branes is considered in section 6. Probe flavour branes in the D3 solution are considered in section 7 and the D4-background is presented in section 8. We conclude and discuss future directions in section 9. We include some appendices that supplement the material of the main body of the work. In appendix A we explain our notation and our conventions. In appendix B we present some explicit geometrical results related to the unit N-sphere. Finally, in appendix C we present very briefly the equations of motion for the scalar mesons in the probe-brane setups under consideration and state the tuned parameters that are necessary to obtain the mass eigenvalues in the cases that do not admit analytic solutions.

2 Background spacetime, probe-brane geometries, and the general approach

In this section we wish to establish notation and conventions, as well as set the stage for the analysis of the forthcoming sections. The analysis presented below in section 2.1 and section 2.2 has been performed a number of times in the past [20, 21, 39], however we do find it convenient and useful to quote once more the basic results here.

2.1 The background geometry

We will be considering the brane junctions of a Dp-brane and a Dk-brane (under the assumption that $p \leq k$) along a number $d$ of common spatial dimensions such that the system is 1/2-BPS. We will denote this intersection by $\{d, p, k\}$. The lower dimensional brane is treated as the background one, while we treat the other one as the probe. Taking into consideration the above physical constraints, one can verify that there are three possibilities for consistent intersections: $\{p, p, p + 4\}$, $\{p - 1, p, p + 2\}$, and $\{p - 2, p, p\}$.

The supergravity background geometry that describes a stack of $N_c$ coincident Dp-branes is given by

$$ds^2 = \frac{1}{\sqrt{H_p}} dx^\mu dx_\mu + \sqrt{H_p} d\vec{Z} \cdot d\vec{Z},$$

written in the string frame. The $\mu$ is taking values over a $(p + 1)$-dimensional Minkowski spacetime parallel to the branes, while the $Z$-coordinates parametrize the $(9-p)$-dimensional
transverse space. In the above, \( p \leq 4 \), while the expression of the harmonic function \( H_p \) is of the following form

\[
H_p = 1 + \left( \frac{R}{r} \right)^{7-p},
\]

with \( R \) being given by

\[
R^{7-p} = 2^{5-p} \pi^{(5-p)/2} g_s N_c \frac{(7-p)}{2} \left( \alpha' \right)^{(7-p)/2},
\]

where in the above \( N_c \) is the number of the background \( Dp \)-branes, \( g_s \) is the string coupling constant, and \( \alpha' \) is the inverse string tension. We will be working in the decoupling limit where the open string modes decouple from the closed string modes, thus, \( \alpha' \to 0 \) and

\[
\lim_{\alpha' \to 0} g_{YM} = \lim_{\alpha' \to 0} (2\pi)^{p-2} g_s \frac{\alpha' (p-3)/2}{2} = \text{fixed}.
\]

Taking the near-horizon limit, the geometry of eq. (2.1) takes the form

\[
ds^2 = \left( \frac{r}{R} \right)^{\frac{2-p}{2}} dx^\mu dx_\mu + \left( \frac{R}{r} \right)^{\frac{2-p}{2}} d\vec{Z} \cdot d\vec{Z},
\]

while the dilaton and the Ramond-Ramond (R-R) potential can be expressed in terms of the \( r \)-coordinate as follows

\[
e^\phi = \left( \frac{R}{r} \right)^{(7-p)(3-p)/4}, \quad C_{(p+1)} = \left( \frac{R}{r} \right)^{7-p} dz^0 \wedge \ldots \wedge dz^p.
\]

For probe embeddings a particular useful re-parametrization of the near-horizon geometry is to choose spherical coordinates and re-express the spacetime. This can be achieved as follows: consider the introduction of the probe \( Dk \)-brane in this background which extends along the directions

\[
X^A = \{ t, x^1, x^2, \ldots, x^d, Y^1, Y^2, \ldots, Y^{k-d} \}.
\]

The hatted capital Latin indices denote the coordinates of the probe \( Dk \)-brane. It is worthwhile stressing that the set of \( Y \)-coordinates describes directions that are transverse to the background \( Dp \)-brane, which means that they coincide with some of the \( Z \)-coordinates. The rest of the \( Z \)-coordinates which are transverse to both background and probe branes will be denoted with \( \vec{w} \), namely

\[
\vec{w} = \{ w^1, w^2, \ldots, w^{9-p-k+d} \},
\]

with \( w^m = Z^{k-d+m} \), and \( m = 1, 2, \ldots, 9 - p - k + d \). In order to introduce spherical coordinates on the world-volume of the \( Dk \)-brane that is transverse to the \( Dp \)-brane, we define

\[
Y^1 = \rho \cos \theta_1, \\
Y^2 = \rho \sin \theta_1 \cos \theta_2, \\
\vdots \\
Y^{k-d-1} = \rho \sin \theta_1 \sin \theta_2 \cdots \sin \theta_{k-d-2} \cos \theta_{k-d-1}, \\
Y^{k-d} = \rho \sin \theta_1 \sin \theta_2 \cdots \sin \theta_{k-d-2} \sin \theta_{k-d-1},
\]

- 7 -
which results to
\[(Y^1)^2 + (Y^2)^2 + \cdots + (Y^{k-d})^2 = \rho^2, \quad (2.10)\]
and
\[(dY^1)^2 + (dY^2)^2 + \cdots + (dY^{k-d})^2 = d\rho^2 + \rho^2 d\Omega^2_{k-d-1}. \quad (2.11)\]
In the above relation
\[d\Omega^2_{k-d-1} = d\theta^2_1 + \sum_{i=2}^{k-d-1} \left( \frac{1}{i-1} \prod_{j=1}^{i-1} \sin^2 \theta_j \right) d\theta^2_i, \quad (2.12)\]
is the line element of the unit \((k - d - 1)\)-dimensional sphere.

Consequently, decomposing the \(Z\)-coordinates in the \(Y\) and \(w\)-coordinates, which are parallel and transverse to the \(Dk\)-brane, respectively, we are led to
\[ds^2 = \left( \frac{r}{R} \right)^{\frac{7-p}{2}} \sum_{\mu,\nu=0}^{p} \eta_{\mu\nu} \, dx^{\mu} \, dx^{\nu} + \left( \frac{R}{r} \right)^{\frac{7-p}{2}} \left( d\rho^2 + \rho^2 \, d\Omega^2_{k-d-1} + \sum_{m,n=1}^{9-p-k+d} \delta_{mn} \, dw^{m} \, dw^{n} \right), \quad (2.13)\]
where \(r^2 = \rho^2 + \sum_{m=1}^{9-p-k+d} (w^m)^2\).

2.2 The geometries on the probe branes

Let us start by considering the embedding of \(D(p + 4)\) branes, with \(0 \leq p \leq 4\). We embed the flavour probe-brane in the \(x^{p+5}, x^{p+6} \cdots x^9\)-plane at a constant position \(|\vec{w}| = L \neq 0\).

The induced geometry on the probe can be written as
\[ds^2 = \left( \frac{r}{R} \right)^{\frac{7-p}{2}} ds^2(\mathbb{M}^{1,p}) + \left( \frac{R}{r} \right)^{\frac{7-p}{2}} \, d\rho^2 + \left( \frac{R}{r} \right)^{\frac{7-p}{2}} \rho^2 \, d\Omega^2_3. \quad (2.14)\]
where \(\mathbb{M}^{(1,p)}\) denotes the \((1 + p)\)-dimensional Minkowski spacetime. The boundary gauge theory is a \((p + 1)\)-dimensional SYM theory coupled to a matter hypermultiplet in the fundamental representation of the gauge group and the quark mass is proportional to the distance \(L\) that separates the two different branes. In case of \(p = 3\) the induced geometry in the UV limit \((r = \rho \rightarrow \infty)\) spans an \(AdS_5 \times S^3\) spacetime.

Now, we want to consider the supersymmetric embedding of \(D(p + 2)\) branes, with \(1 \leq p \leq 4\). In this case the dual gauge theory is \((p + 1)\)-dimensional with the fundamental hypermultiplet confined on a \(p\)-dimensional surface. The induced geometry is equal to
\[ds^2 = \left( \frac{r}{R} \right)^{\frac{7-p}{2}} ds^2(\mathbb{M}^{(1,p-1)}) + \left( \frac{R}{r} \right)^{\frac{7-p}{2}} \, d\rho^2 + \left( \frac{R}{r} \right)^{\frac{7-p}{2}} \rho^2 \, d\Omega^2_3. \quad (2.15)\]
In case of \(p = 3\) the induced geometry in the UV limit spans an \(AdS_4 \times S^2\) geometry.

Finally, we want to consider embedding probe \(Dp\)-branes in the background of geometry of \(Dp\)-branes with \(2 \leq p \leq 4\). The matter field of fundamental hypermultiplet propagate in a co-dimension two defect; the hypermultiplet is confined on a \((p - 1)\)-dimensional surface. The geometry on the probe brane can be written as
\[ds^2 = \left( \frac{r}{R} \right)^{\frac{7-p}{2}} ds^2(\mathbb{M}^{(1,p-2)}) + \left( \frac{R}{r} \right)^{\frac{7-p}{2}} \, d\rho^2 + \left( \frac{R}{r} \right)^{\frac{7-p}{2}} \rho^2 \, d\Omega^2_2. \quad (2.16)\]
In case of \(p = 3\) the induced geometry in the UV limit spans an \(AdS_3 \times S^1\) spacetime.
2.3 Vielbeins & spin-connection components

An appropriate choice of basis will be proven very helpful for the forthcoming calculations, thus, using the vielbein formalism — for which it holds that $g_{MN} = e^{(A)}_{M} e^{(B)}_{N} \eta_{(A)(B)}$ — in the geometry of eq. (2.13), it is straightforward to evaluate the following quantities:

\[ e^{(A)}_{\mu} = \left( \frac{r}{R} \right) \frac{7-p}{4} \delta^{A}_{\mu}, \quad e^{(A)}_{\rho} = \left( \frac{R}{r} \right) \frac{7-p}{4} \delta^{A}_{\rho}, \]  
\[ e^{(A)}_{i} = \rho \left( \frac{R}{r} \right) \frac{7-p}{4} \theta^{(A)}_{i}, \quad i = 1, \ldots, k - d - 1, \]  
\[ e^{(A)}_{m} = \left( \frac{R}{r} \right) \frac{7-p}{4} \delta^{A}_{m}, \quad m = 1, \ldots, 9 - p - k + d, \]  

where the indices with bar correspond to the spherical coordinates $\{\theta_1, \ldots, \theta_{k-d-1}\}$, while the indices with tilde correspond to the coordinates $\{w^1, \ldots, w^{9-p-k+d}\}$. In addition, the quantity $\tilde{e}^{(A)}_{i}$ represents the vielbein of $S^{k-d-1}$; its explicit expression is given in appendix B. The vielbein basis $\{e^{(A)}_M = e^{(A)}_M dx^M\}$, satisfy the following relation

\[ ds^2 = g_{MN} dx^M dx^N = \eta_{(A)(B)} e^{(A)} e^{(B)}. \]  

We also present below the non-zero components of the spin-connection. We remind the readers that for torsion-free theories the definition is

\[ \omega^{(A)(B)}_{M} = e^{(A)}_{N} \Gamma^{N}_{ML} e^{(B)L} + e^{(A)}_{N} \partial_{M} e^{(B)N}, \]  

where $e^{(A)M} = e^{(A)N} g^{NM} = \eta^{(A)(B)} e^{(B)M}$. Using eq. (2.22) we obtain the following spin-connection components:

\[ \omega^{(A)(B)}_{\mu} = \frac{7-p}{4} \frac{1-p}{r^2} \left[ \rho \left( \delta_{\mu}^{A} \delta_{\rho}^{B} - \delta_{\rho}^{A} \delta_{\mu}^{B} \right) + w^{m} (\delta_{m}^{A} \delta_{\mu}^{B} - \delta_{\mu}^{A} \delta_{m}^{B}) \right], \]  
\[ \omega^{(A)(B)}_{\rho} = \frac{7-p}{4} \frac{1-p}{r^2} \left( \delta_{\rho}^{A} \delta_{\mu}^{B} - \delta_{\mu}^{A} \delta_{\rho}^{B} \right), \]  
\[ \omega^{(A)(B)}_{k} = \omega^{(A)(B)}_{k} + \left[ \frac{(7-p)B^2}{4r^2} - 1 \right] \left( \delta_{\rho}^{A} \tilde{e}^{(B)}_{k} - \delta_{k}^{A} \tilde{e}^{(B)}_{\rho} \right) + \frac{(7-p)\rho w^{m}}{4r^2} \left( \delta_{m}^{A} \tilde{e}^{(B)}_{k} - \delta_{k}^{A} \tilde{e}^{(B)}_{m} \right), \]  
\[ \omega^{(A)(B)}_{m} = \frac{(7-p)B^2}{4r^2} \left[ \rho \left( \delta_{\mu}^{A} \delta_{\rho}^{B} - \delta_{\rho}^{A} \delta_{\mu}^{B} \right) + w^{n} (\delta_{n}^{A} \delta_{\mu}^{B} - \delta_{\mu}^{A} \delta_{n}^{B}) \right], \]  

where the quantity $\tilde{\omega}^{(A)(B)}_{k}$ constitutes the spin-connection of $S^{k-d-1}$; its explicit expression is given in appendix B as well.

---

\[ \text{Indices between brackets will be used solely to denote vielbein indices.} \]

\[ \text{The dual basis} \left\{ e^{(A)}_{M} = e^{(A)M} \partial_{M} \right\} \text{is defined through the relation} \]

\[ e^{(A)}_{(e^{(B)})} = e^{(A)}_{M} dx^{M} (e^{(B)N} \partial_{N}) = e^{(A)}_{M} e^{(B)N} \delta^{M}^{N} = \delta^{(A)}_{(B)}. \]  

---
2.4 The Dirac operator

The Dirac operator for fermionic fields on a generic curved manifold is defined by

$$\slashed{D} = \Gamma^N e_{(N)}^M \left( \partial_M + \frac{1}{8} \omega^{(K)(L)}_M [\Gamma_K, \Gamma_L] \right) = \Gamma^N e_{(N)}^M \left( \partial_M + \frac{1}{4} \omega^{(K)}_M \Gamma_{KL} \right). \quad (2.27)$$

In what follows, we compute the Dirac operator for the general case that we consider here; the embedding of a probe D$k$-brane in the background generated by D$p$-branes. Note that for a probe D$k$ the index $M$ in eq. (2.27) should be replaced by $\hat{M}$, which runs over the probe brane coordinates. After a straightforward computation we are led to

$$\slashed{D}_{Dk} = \frac{R^{\frac{7-p}{2}}}{r^{\frac{7-p}{2}}} \Gamma^\mu \partial_\mu + \frac{r^{\frac{7-p}{2}}}{R^{\frac{7-p}{2}}} \Gamma^\rho \partial_\rho + \frac{1}{\rho} \frac{r^{\frac{7-p}{2}}}{R^{\frac{7-p}{2}}} \slashed{D}_{Sk-d-1}$$

$$+ \frac{1}{R^{\frac{7-p}{2}}} \left[ \frac{(7-p)(p-2)}{8} \frac{\rho}{r^{\frac{7-p}{2}}} + \frac{1}{2} \frac{r^{\frac{7-p}{2}}}{\rho} (k-d-1) \right] \Gamma^\rho$$

$$+ \frac{7-p}{8} \frac{1}{R^{\frac{7-p}{2}}} \frac{1}{r^{\frac{7-p}{2}}} (2d+1-k) \sum_{m=1}^{9-p-k+d} w^m \Gamma^\rho_{\hat{m}}, \quad (2.28)$$

with

$$\slashed{D}_{Sk-d-1} = \Gamma^N e_{(N)}^k \left( \partial_k + \frac{1}{4} \omega^{(K)(L)}_k \Gamma_{KL} \right). \quad (2.29)$$

We have already mentioned that the consistent intersections — characterized by the set of numbers $\{d, p, k\}$ — between the background D$p$- and probe D$k$-branes, are: $\{p, p, p + 4\}$, $\{p - 1, p, p + 2\}$, and $\{p - 2, p, p\}$. One can easily verify that in all cases $2d + 1 - k = p - 3$, thus, eq. (2.28) can be written as

$$\slashed{D}_{Dk} = \frac{R^{\frac{7-p}{2}}}{r^{\frac{7-p}{2}}} \Gamma^\mu \partial_\mu + \frac{r^{\frac{7-p}{2}}}{R^{\frac{7-p}{2}}} \Gamma^\rho \partial_\rho + \frac{1}{\rho} \frac{r^{\frac{7-p}{2}}}{R^{\frac{7-p}{2}}} \slashed{D}_{Sk-d-1}$$

$$+ \frac{1}{R^{\frac{7-p}{2}}} \left[ \frac{(7-p)(p-2)}{8} \frac{\rho}{r^{\frac{7-p}{2}}} + \frac{1}{2} \frac{r^{\frac{7-p}{2}}}{\rho} (k-d-1) \right] \Gamma^\rho$$

$$- \frac{(7-p)(3-p)}{8} \frac{1}{R^{\frac{7-p}{2}}} \frac{1}{r^{\frac{7-p}{2}}} \sum_{m=1}^{9-p-k+d} w^m \Gamma^\rho_{\hat{m}}. \quad (2.30)$$

3 D0 branes: supersymmetric matrix quantum mechanics

In the background generated by a stack of D0-branes there is a unique way to arrange the flavour branes which we demonstrate in Table 1. The fermionic action [24–26] is given by

$$S_{D4} = \frac{T_{D4}}{2} \int d^5 \xi \sqrt{-g} \Psi_+ \left[ \slashed{D}_{D4} - \frac{e^\phi}{8 \cdot 2!} F_{AB} \left( \hat{\Gamma}^{\hat{M}} \Gamma^{AB} \Gamma^{(10)} \hat{\Gamma}^{\hat{M}} + 3 \Gamma^{AB} \Gamma^{(10)} \right) - \frac{1}{2} \Gamma^M \partial_M \phi \right] \Psi_+$$

In the above, $(T_{Dk})^{-1} = (2\pi)^k (a')^{\frac{k+1}{2}} g_s$ is the brane tension, $\Psi_-$ is a $\kappa$-symmetry projector ensuring $\kappa$-symmetry invariance of the action, and $F_{AB}$ represents the components of the
Table 1. The brane intersection. In the above notation — denotes that a brane extends along that particular direction, while • means that the coordinate is transverse to the brane.

2-form R-R field strength. With the use of eq. (2.6) and setting $p = 0$ it is straightforward to determine both the dilaton field

$$e^\phi = \left(\frac{R}{r}\right)^\frac{21}{4},$$

(3.2)

and the 2-form R-R field strength

$$F_{(2)} = dC_{(1)} = -\frac{7r^5}{R^7} e^{(0)} \wedge \left(\rho e^{(\rho)} + \sum_{i=1}^{5} w^i e^{(w^i)}\right).$$

(3.3)

In addition, $\Gamma^{(10)} = \Gamma^{01-\rho\rho_1-\theta_1-\cdots-\theta_{k-\rho_{k-1}}-\cdots-\rho_{k-1+4\rho}}$ is the ten-dimensional chiral operator, $\hat{g}_{\hat{M}\hat{N}} = P[\hat{g}]_{\hat{M}\hat{N}}$ is the pullback of the background metric $g_{MN}$ on the worldvolume, while $\hat{g}$ constitutes the determinant of the aforementioned metric.

Varying eq. (3.1) with respect to the conjugate spinor $\bar{\Psi}$, we readily obtain the equation of motion of the spinor $\Psi$ ($\Psi$ is a ten-dimensional spinor of positive chirality $\Gamma^{(10)}\Psi = \Psi$), namely

$$\hat{D}_{D4}\Psi - \frac{e^\phi}{8 \cdot 2!} F_{AB} \left(\Gamma^M \Gamma^{AB} \Gamma^{(10)} \Gamma_M + 3 \Gamma^{AB} \Gamma^{(10)}\right) \Psi - \frac{1}{2} (\Gamma^M \partial_M \phi) \Psi = 0.$$  

(3.4)

Using eqs. (3.2) and (3.3) together with the properties of $\Gamma^M$ matrices, we can evaluate

$$\frac{e^\phi}{8 \cdot 2!} F_{AB} \left(\Gamma^M \Gamma^{AB} \Gamma^{(10)} \Gamma_M + 3 \Gamma^{AB} \Gamma^{(10)}\right) \Psi = -\frac{7}{4R^{7/4}r^{17/4}} \Gamma^{00\rho} \Psi = -\frac{7}{4R^{7/4}r^{17/4}} \Gamma^{00\rho} \Psi,$$

(3.5)

while by setting $p = d = 0$ and $k = 4$ in eq. (2.28) we are led to

$$\hat{D}_{D4}\Psi = \left\{ \left(\frac{R}{r}\right)^\frac{7}{4} \Gamma^\mu \partial_\mu + \left(\frac{r}{R}\right)^\frac{7}{4} \Gamma^\rho \partial_\rho + \frac{1}{\rho} \left(\frac{r}{R}\right)^\frac{7}{4} \hat{D}_{S^3} + \frac{1}{R^{\frac{17}{4}}} \left(\frac{7}{4} \rho^\frac{7}{4} + \frac{3r^\frac{7}{4}}{2\rho}\right) \Gamma^\rho \right.\right.$$ 

$$\left. - \frac{21}{8} \frac{1}{R^7 r^{\frac{17}{4}}} \sum_{i=1}^{5} w^i \Gamma_{w^i}\right\} \Psi.$$  

(3.6)

For the spherical piece we can utilize the spinor spherical harmonics [40]

$$\hat{D}_{S^3}\Psi^{\ell\pm} = \pm \left(\ell + \frac{3}{2}\right) \Psi^{\ell\pm}.$$  

(3.7)

It is also important to notice that the above calculations have been performed in the vielbein basis $\{e^{(M)}\}$ (see for example the expression of the R-R field strength) instead of
the usual \( \{ dx^M \} \). Thus, we should recognise that \( \Gamma^M \partial_M \phi \) is in fact \( \Gamma^N e_{(N)}^M \partial_M \phi \). From eq. (2.6) and after a straightforward calculation, we get
\[
\Gamma^M \partial_M \phi \rightarrow \Gamma^N e_{(N)}^M \partial_M \phi = -\frac{21}{4} \frac{\rho}{R^3} \frac{1}{\rho^2} \left( \rho \Gamma^\rho + \sum_{i=1}^{5} w^i \Gamma_w \right). \quad (3.8)
\]

Consequently, substituting eqs. (3.5)–(3.8) in eq. (3.4) and imposing the projection \( \partial_\rho \Psi = -\Psi \), we are led to the following first-order equation of motion
\[
\left\{ \left( \frac{R}{r} \right)^{\frac{7}{2}} \Gamma^\rho \partial_\rho + \left( \frac{r}{R} \right)^{\frac{7}{2}} \Gamma^\rho \partial_\rho + \frac{1}{R^3} \left[ \frac{7}{4} \frac{\rho}{\rho^2} \pm \left( \ell + \frac{3}{2} \right) \frac{r^2}{\rho} \right] + \frac{1}{R^3} \left( \frac{7}{8} \frac{\rho^2}{\rho^4} + \frac{3}{2} \frac{r^2}{\rho} \right) \Gamma^\rho \right\} \Psi^{\ell \pm} = 0. \quad (3.9)
\]

In what follows we consider that \( \sum_{i=1}^{5} (w^i)^2 = L^2 \), which by its turn leads to \( r^2 = \rho^2 + L^2 \). \( L \) constitutes the distance between the D0- and the D4-branes in the \( x^5 x^6 x^7 x^8 x^9 \)-hyperplane of the 10-dimensional spacetime. Acting with the operator \( \left( \frac{r}{R} \right)^{7/4} \Gamma^\rho \partial_\rho + \left( \frac{R}{r} \right)^{7/4} \Gamma^\rho \partial_\rho \) on the l.h.s. of eq. (3.9), and then using the Clifford algebra and the first-order equation of motion eq. (3.9), it is possible to re-express some of the terms appropriately such that we derive an ordinary, second-order differential equation of the following form
\[
\left( \mathcal{A}_1^{\pm} \partial_\rho^2 + \mathcal{A}_2^{\pm} \partial_\rho + \mathcal{A}_3^{\pm} \right) M^2 + \mathcal{A}_4^{\pm} \Gamma^\rho + \mathcal{A}_5^{\pm} \right) \psi^{\ell \pm} (\rho) = 0, \quad (3.10)
\]
where we have used the decomposition \( \Psi^{\ell \pm} (x^\lambda, \rho) = e^{i \kappa_k x^k} \psi^{\ell \pm} (\rho) \) and the relation \( M^2 = -\eta^{\mu \nu} k_\mu k_\nu \).\(^{3}\) In addition, we have also used the dimensionless quantities \( \rho = \rho/L \), \( M^2 = M^2 R^7 / L^5 \). The \( \mathcal{A} \) factors which appropriately describe the second-order equation are shown below:
\[
\mathcal{A}_1^{\pm} = 1, \quad \mathcal{A}_2^{\pm} = \frac{3}{\rho} + \frac{21}{4} \frac{\rho}{\rho^2 + 1}, \quad \mathcal{A}_3^{\pm} = \frac{1}{(\rho^2+1)^{7/2}}, \quad \mathcal{A}_4^{\pm} = \frac{7}{4} \frac{1 \pm 2 \ell \pm 3}{\rho^2 + 1} + \frac{1}{\rho^2} \left( \ell + \frac{3}{2} \right) + \frac{21}{8} \frac{\rho^2}{(\rho^2 + 1)^2}, \quad (3.12)
\]
\[
\mathcal{A}_5^{\pm} = \frac{7}{4} \frac{1 \pm 2 \ell \pm 3}{\rho^2 + 1} \left( 5 \pm 3 + 2 \ell \right) - \frac{63}{64} \frac{\rho^2}{(\rho^2 + 1)^2} - \frac{1}{\rho^2} \left( \ell^2 + 3 \ell + \frac{3}{2} \right). \quad (3.12)
\]

In the above equations, the plus sign in the \( \mathcal{A} \) factors denotes the positive eigenvalue of the spinorial harmonics (\( \mathcal{G} \) operators) and the negative sign superscript is related to the negative eigenvalue (\( \mathcal{F} \) operators). Moreover, the projection \( \Gamma^\rho \Psi = \pm \Psi \) (or \( \Gamma^\rho \psi = \pm \psi \)) generates two additional second-order differential equations when it is applied to eq. (3.10). The spinor which under the aforementioned projection remains invariant will be denoted by \( \Psi^{\nabla} \) (or \( \psi^{\nabla} \)), while \( \Psi^{\nabla} \) (or \( \psi^{\nabla} \)) will represent the spinor which under the same projection goes to minus itself. Therefore, we can distinguish the following cases:

\[^{3}\)This particular decomposition results to
\[
\Gamma^\rho \partial_\rho \psi^{\ell \pm} = -(\partial_\rho \psi^{\ell \pm} - k_\mu k_\nu \Gamma^\rho \psi^{\ell \pm} = -k_\mu k_\nu (2 \eta^{\mu \nu} \delta_{32} - \Gamma^\rho \Gamma^\nu) \psi^{\ell \pm} = 2 M^2 \psi^{\ell \pm} + k_\mu k_\nu \Gamma^\rho \Gamma^\nu \psi^{\ell \pm} \quad \mu, \nu \in \{0, 1, 2, 3, 4\} \Rightarrow -k_\mu k_\nu \Gamma^\rho \Gamma^\nu \psi^{\ell \pm} = M^2 \psi^{\ell \pm} \Rightarrow
\]
\[
\Gamma^\rho \partial_\rho \psi^{\ell \pm} = M^2 \psi^{\ell \pm}. \quad (3.11)
\]
(i) Positive spinorial harmonics eigenvalues:

• Positive $\Gamma^e$-projection:

\[
\left( A_1^+ \partial^2_\varrho + A_2^+ \partial_\varrho + A_3^+ \tilde{M}^2 + A_4^+ + A_5^+ \right) \psi^\varrho_\ell^p (\varrho) = 0 \Rightarrow \\
\left[ \partial^2_\varrho + \left( \frac{3}{\varrho} + \frac{21}{4} \frac{\varrho}{\varrho^2 + 1} \right) \partial_\varrho + \frac{\tilde{M}^2}{(\varrho^2 + 1)^{7/2}} - \frac{1}{\varrho^2} (\ell^2 + 4\ell + 3) + \frac{21}{2} \frac{1}{\varrho^2 + 1} + \frac{105}{64} \frac{\varrho^2}{(\varrho^2 + 1)^2} \right] \psi^\varrho_\ell^p (\varrho) = 0. \\
(3.13)
\]

• Negative $\Gamma^e$-projection:

\[
\left( A_1^+ \partial^2_\varrho + A_2^+ \partial_\varrho + A_3^+ \tilde{M}^2 - A_4^+ + A_5^+ \right) \psi^\varrho_\ell^p (\varrho) = 0 \Rightarrow \\
\left[ \partial^2_\varrho + \left( \frac{3}{\varrho} + \frac{21}{4} \frac{\varrho}{\varrho^2 + 1} \right) \partial_\varrho + \frac{\tilde{M}^2}{(\varrho^2 + 1)^{7/2}} - \frac{1}{\varrho^2} (\ell^2 + 2\ell) - \frac{7}{2} \frac{1 + 2\ell}{\varrho^2 + 1} - \frac{231}{64} \frac{\varrho^2}{(\varrho^2 + 1)^2} \right] \psi^\varrho_\ell^p (\varrho) = 0. \\
(3.14)
\]

(ii) Negative spinorial harmonics eigenvalues:

• Positive $\Gamma^e$-projection:

\[
\left( A_1^- \partial^2_\varrho + A_2^- \partial_\varrho + A_3^- \tilde{M}^2 + A_4^- + A_5^- \right) \psi^\varrho_\ell^p (\varrho) = 0 \Rightarrow \\
\left[ \partial^2_\varrho + \left( \frac{3}{\varrho} + \frac{21}{4} \frac{\varrho}{\varrho^2 + 1} \right) \partial_\varrho + \frac{\tilde{M}^2}{(\varrho^2 + 1)^{7/2}} - \frac{1}{\varrho^2} (\ell^2 + 2\ell) + \frac{21}{2} \frac{1}{\varrho^2 + 1} + \frac{105}{64} \frac{\varrho^2}{(\varrho^2 + 1)^2} \right] \psi^\varrho_\ell^p (\varrho) = 0. \\
(3.15)
\]

• Negative $\Gamma^e$-projection:

\[
\left( A_1^- \partial^2_\varrho + A_2^- \partial_\varrho + A_3^- \tilde{M}^2 - A_4^- + A_5^- \right) \psi^\varrho_\ell^p (\varrho) = 0 \Rightarrow \\
\left[ \partial^2_\varrho + \left( \frac{3}{\varrho} + \frac{21}{4} \frac{\varrho}{\varrho^2 + 1} \right) \partial_\varrho + \frac{\tilde{M}^2}{(\varrho^2 + 1)^{7/2}} - \frac{1}{\varrho^2} (\ell^2 + 4\ell + 3) + \frac{7}{2} \frac{5 + 2\ell}{\varrho^2 + 1} - \frac{231}{64} \frac{\varrho^2}{(\varrho^2 + 1)^2} \right] \psi^\varrho_\ell^p (\varrho) = 0. \\
(3.16)
\]
Figure 1. (a) The solution obtained from the positive eigenvalue of the $\Gamma^\rho$ projector, while (b) refers to the negative eigenvalue of the $\Gamma^\rho$ projector. Both of them are dual to the field theory $F$ modes for quantum numbers $n = 0, \ell = 3$.

It is straightforward to see that applying $p = 0$ in eq. (C.2) yields the corresponding bosonic equation of motion for the D0/D4-brane system, namely, it is

$$\partial^2 \varphi f(\varphi) + \frac{3}{\varphi} \partial_\varphi f(\varphi) + \left[ \frac{M^2}{(1 + \varphi^2)^{7/2}} - \frac{\ell(\ell + 2)}{\varphi^2} \right] f(\varphi) = 0. \quad (3.17)$$

One can easily verify that the transformation

$$\psi_{G_\ell}^{\otimes}(\varphi) = \frac{1}{(1 + \varphi^2)^{21/16}} f_{\ell+1}(\varphi), \quad (3.18)$$

maps eq. (3.13) to eq. (3.17) for $\ell \to \ell + 1$, while the transformation

$$\psi_{F_\ell}^{\otimes}(\varphi) = \frac{1}{(1 + \varphi^2)^{21/16}} f_{\ell}(\varphi), \quad (3.19)$$

maps eq. (3.15) to eq. (3.17). Notice that the above transformations can be obtained from (1.1) by setting $p = 0$. In contrast, eqs. (3.14) and (3.16) cannot be mapped to eq. (3.17). This particular behaviour is anticipated due to the structural difference of the two separate equations of motion obtained by the application of the two different projection eigenvalues of the $\Gamma^\rho$ matrix. In order to demonstrate their difference, we simply plot the mode-solutions from which we obtain the correct mass squared eigenvalues, see figures 1 and 2. At this point, it is important to mention that the quantum number $n$ counts the nodes of the functions $\psi_{G_\ell}^{\otimes}$ and $\psi_{F_\ell}^{\otimes}$; it is clear that in both figures 1 and 2 the quantum number $n$ is zero. From these plots it is also very clear how we must shift appropriately the quantum number $\ell$ such that all the states are part of the same massive supermultiplet as dictated in [15]. We have employed this shift in the $\ell$ quantum number in all the tables with our numerical results such that we keep our presentation short. While we have provided appropriate transformations such that we analytically map the fermionic degrees of freedom to the bosonic ones, eqs. (3.18) and (3.19), here we demonstrate the numerical approach that we used to determine the mass eigenvalues directly from the second order equations of motion for the D0/D4 brane junction. The same numerical approach was of course used to compute the solutions in figures 1 and 2.
We are shooting from the $\Lambda_{\text{IR}}$ to the $\Lambda_{\text{UV}}$ by fine-tuning $\bar{M}^2$ such that the mode solutions are normalizable in the UV and small in amplitude [15].

- We use $\Lambda_{\text{IR}} = 10^{-7}$ and $\Lambda_{\text{UV}} = 10$.

- For the initial conditions we use

  \begin{align*}
  \psi_{\bar{G},+}(\varrho) |_{\varrho \to 0} = \varrho^{\ell+1}, \quad &\partial_\varrho \psi_{\bar{G},+}(\varrho) |_{\varrho \to 0} = (\ell + 1)\varrho^\ell, \\ 
  \psi_{\bar{G},-}(\varrho) |_{\varrho \to 0} = \varrho^\ell, \quad &\partial_\varrho \psi_{\bar{G},-}(\varrho) |_{\varrho \to 0} = \ell\varrho^{\ell-1}, \\ 
  \psi_{\mathcal{F},+}(\varrho) |_{\varrho \to 0} = \varrho^\ell, \quad &\partial_\varrho \psi_{\mathcal{F},+}(\varrho) |_{\varrho \to 0} = \ell\varrho^{\ell-1}, \\ 
  \psi_{\mathcal{F},-}(\varrho) |_{\varrho \to 0} = \varrho^{\ell+1}, \quad &\partial_\varrho \psi_{\mathcal{F},-}(\varrho) |_{\varrho \to 0} = (\ell + 1)\varrho^\ell.
  \end{align*}

We show explicitly the first few numerical values of the masses in Table 2. The numerical values for $n$ and $\ell$ describe the $\mathcal{F}$ operators and one needs to shift appropriately the $\ell$ to read off the value of the $\mathcal{G}$ states. We have also explicitly checked that we obtain the same spectrum from eq. (3.17). In order to perform the numerical analysis for the bosonic degrees of freedom we used as initial conditions $f(\varrho) |_{\varrho \to 0} = \varrho^\ell$ and $\partial_\varrho f(\varrho) |_{\varrho \to 0} = \ell\varrho^{\ell-1}$ [20, 21] and the other parameters are the same as previously.

As a final project within the D0/D4 brane setup, we are demonstrating explicitly that the $\bar{M}^2$ value can be obtained from either the positive or the negative eigenvalues of the $\Gamma^e$ projector.
Figure 3. For both (a) and (b), the masses are $\bar{M}^2 = 169$ (blue), 169.0736 (red), 169.1 (green) (from top to bottom). The parameters $n$ and $\ell$ are the same as in figure 1, namely $n = 0$, $\ell = 3$. We have zoomed in to the plots in order to show the behaviour near the UV cut-off. Clearly the red line, which is the correct solution, can be uniquely determined from either positive or negative $\Gamma^\rho$-projections.

Figure 4. For both (a) and (b), the masses are $\bar{M}^2 = 169$ (blue), 169.0736 (red), 169.1 (green) (from top to bottom). The parameters $n$ and $\ell$ are the same as in figure 2, namely $n = 0$, $\ell = 2$. We have zoomed in to the plots in order to show the behaviour near the UV cut-off. Clearly the red line, which is the correct solution, can be uniquely determined from either positive or negative $\Gamma^\rho$-projections.

matrix. This statement holds true of course for both the string modes dual to the $\mathcal{F}$ and $\mathcal{G}$ modes. In order to do so, we predict the mass of the $n = 0$, $\ell = 2$ for the supergravity modes dual to the $\mathcal{G}$ operators (the ones associated with the positive eigenvalue of the spinor spherical harmonics) and the $n = 0$, $\ell = 3$ state of the fluctuation dual to the $\mathcal{F}$ operators (related to the negative eigenvalue of the spinor harmonics). Note that these particular $\mathcal{F}$ and $\mathcal{G}$ states should have the same mass, since we are shifting $\ell$ by one. We present our results for the $\mathcal{F}$ modes in Figure 3 and we proceed to the results related to the $\mathcal{G}$ modes, which are shown in Figure 4.
4 The general procedure

In this section, we present the necessary mathematical machinery for computing the equation of motion and solve for the mass eigenvalues of the world-volume fermions in all possible probe-brane setups. The main task at hand, in order to determine the equations of motion and solve for the mass eigenvalues, is to derive a second-order ordinary differential equation of a scalar function depending on the holographic radial coordinate. To do so, we:

- Compute the vielbein and the spin-connection components of the background geometry from eqs. (2.17)–(2.19) and (2.23)–(2.26).
- Compute the dilaton field and the R-R field strength from eq. (2.6). In addition, we re-express the R-R field strength components in the vielbein basis.
- Write the curved $\Gamma$-matrices in terms of flat ones. It is also worthwhile commenting that we do not need an explicit representation of these matrices as we will be dealing only with projectors. These can be computed by means of the Clifford algebra and general properties that the generators of the algebra satisfy.
- Obtain the equation of motion for the ten-dimensional spinor $\Psi$ by varying the fermionic DBI action with respect to the conjugate spinor $\bar{\Psi}$.
- Determine the first-order differential equation of the spinor using the explicit expression of the Dirac operator given by eq. (2.28) or (2.30). For the spherical piece we can utilize the spinor spherical harmonics [40]

\[
\mathcal{D}_{Sk_{d-1}} \Psi^{\ell \pm} = \pm \left( \ell + \frac{k - d - 1}{2} \right) \Psi^{\ell \pm}, \tag{4.1}
\]

while, for the bulk piece, we use separation of variables for the Minkowski coordinates and the radial coordinate by making a plane-wave ansatz, with the wave-vector satisfying $k^\mu k_\mu = -M^2$ and $M$ being the mass of the fluctuation.

It is also important to stress here that performing the calculations in the vielbein basis $\{e^{(M)}\}$, instead of the usual $\{dx^M\}$, will affect all spacetime derivatives in the spinor equation of motion. Thus, in the $Dp/Dk$-brane systems in which the dilaton field $\phi$ does not vanish, we should keep in mind that $\Gamma^M \partial_M \phi$ in the $\{dx^M\}$ basis will become $\Gamma^N e_{(N)}^M \partial_M \phi$ in the $\{e^{(M)}\}$ basis. From eq. (2.6) and after a straightforward calculation, we find that

\[
\Gamma^N e_{(N)}^M \partial_M \phi = -\frac{(7-p)(3-p)}{4} \frac{1}{R^{\frac{1-p}{2}}} \frac{1}{r^{\frac{p+1}{2}}} \left( \rho \Gamma^p + \sum_{m=1}^{9-p-k+d} w^m \Gamma^m \right). \tag{4.2}
\]
Table 3. The supersymmetric brane intersections. In the above notation — denotes that a brane extends along that particular direction, while • means that the coordinate is transverse to the brane.

|                | $x^0$ | $x^1$ | $x^2$ | $x^3$ | $x^4$ | $x^5$ | $x^6$ | $x^7$ | $x^8$ | $x^9$ |
|----------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| Background D1-brane | —     | —     | •     | •     | •     | •     | •     | •     | •     | •     |
| Probe D3-brane       | •     | —     | —     | —     | —     | —     | —     | —     | —     | —     |
| Probe D5-brane       | —     | —     | —     | —     | —     | —     | —     | —     | —     | —     |

Subtracting now eq. (4.2) from (2.30) we get

$$\mathcal{D}_{Dk}\Psi^{\pm} - \frac{\Gamma N e(N)^2 M \partial M \phi}{2} \Psi^{\pm} = \left\{ \frac{R^{7-p}}{r^{7-p}} \Gamma^\mu \partial_\mu + \frac{r^{7-p}}{R^{7-p}} \Gamma^\rho \partial_\rho \pm \frac{1}{\rho \, r^{7-p}} \left( \ell + \frac{m}{2} \right) \right\} \Psi^{\pm},$$

(4.3)

where we have defined $m \equiv k - d - 1$.

- Once we obtain the first-order equation of motion that the spinor satisfies we act with the differential operator

$$\frac{R^{7-p}}{r^{7-p}} \Gamma^\mu \partial_\mu + \frac{r^{7-p}}{R^{7-p}} \Gamma^\rho \partial_\rho,$$

(4.4)

on this first-order equation of motion. Then, by using some basic identities of the Clifford algebra and after some tedious algebra we derive a second-order ordinary differential equation of the following schematic form

$$\left( A_1 \partial_\varrho^2 + A_2 \partial_\varrho + A_3 \bar{M}^2 + A_4 \Gamma^\varrho + A_5 \right) \psi(\varrho) = 0,$$

(4.5)

where we have also used the dimensionless quantities

$$\varrho = \frac{\rho}{\bar{L}}, \quad \bar{M}^2 = \frac{M^2 R^{7-p}}{L^{5-p}}.$$

(4.6)

In the above, $L^2 = \sum_{m=1}^{9-p-k+d} (w^m)^2$ constitutes the distance between the Dp- and the Dk-branes. $A$'s are the coefficients of interest that we compute explicitly for each case we consider.

5 Fermions in the D1-background

The branes in the D1-background are arranged in the following way, see Table 3.

The fermionic action is given by\(^4\)

$$S_{Dk} = \frac{T_{Dk}}{2} \int d^{k+1} \xi \sqrt{-\bar{g}} \bar{\Psi} \mathcal{D}_{Dk} + \frac{e^\phi}{8 \cdot 3!} F_{ABC} \left( \Gamma^{[\bar{M}} \Gamma^{ABC} \Gamma_{\bar{M}]} + 2 \Gamma^{ABC} \right) - \frac{1}{2} \Gamma^M \partial_M \phi \right\} \Psi.$$

(5.1)

\(^4\)We have written the action using single spinor notation rather than the two-component one. In order to do so we have manipulated appropriately some Pauli matrices as explained in appendix of paper [26].
Varying eq. (5.1) with respect to the conjugate spinor \( \bar{\Psi} \), we readily obtain the equation of motion of the spinor \( \Psi \), namely it is

\[
\mathcal{D}_{\bar{D}k}\Psi + \frac{e^\phi}{8 \cdot 3!}F_{ABC}\left(\Gamma^M\Gamma^{ABC}\Gamma_M + 2\Gamma^{ABC}\right)\Psi - \frac{1}{2}(\Gamma^M\partial_M\phi)\Psi = 0 ,
\]

where the dilaton field is determined from eq. (2.6) with \( p = 1 \), thus

\[
e^\phi = \left(\frac{R}{r}\right)^3 .
\]

As it is depicted in Table 3, there are two possibilities for the probe \( Dk \)-branes. We can either have \( k = 3 \) or \( k = 5 \), with \( d = 0 \) and \( d = 1 \), respectively. The R-R field strength field strength in the D1/Dk-brane setup is a 3-form and it is given by

\[
F_{(3)} = dC_{(2)} = \frac{6r^{5/2}}{R^{9/2}} e^{(0)} \wedge e^{(1)} \wedge \left(\rho e^{(\rho)} + \sum_{i=1}^{8-k+d} w^i e^{(w^i)}\right) .
\]

Having in our disposal the components of the R-R field strength as well as the expression of the dilaton field it is straightforward to calculate that

\[
\frac{e^\phi}{8 \cdot 3!}F_{ABC}\left(\Gamma^M\Gamma^{ABC}\Gamma_M + 2\Gamma^{ABC}\right)\Psi = \frac{3}{2R^{3/2}} \frac{\rho}{\sqrt{r}} \Gamma_0^1\rho\Psi = - \frac{3}{2R^{3/2}} \frac{\rho}{\sqrt{r}} \Gamma_0^1\rho\Psi ,
\]

while by setting \( p = 1 \) in eq. (4.3) we get

\[
\mathcal{D}_{\bar{D}k}\Psi^{\ell\pm} - \frac{\Gamma^M\partial_M\phi}{2} \Psi^{\ell\pm} = \left(\frac{R}{r}\right)^3 \Gamma^\mu\partial_\mu \Psi^{\ell\pm} + \left(\frac{r}{R}\right)^3 \Gamma^\rho\partial_\rho \Psi^{\ell\pm} \pm \frac{1}{\rho} \left(\frac{r}{R}\right)^3 \left(\ell + \frac{m}{2}\right) \Psi^{\ell\pm}
\]

\[
+ \frac{1}{R^2} \left(\frac{3}{4} \frac{\rho}{\sqrt{r}} + \frac{m r^2}{2 \rho}\right) \Gamma^\rho \Psi^{\ell\pm} ,
\]

where \( m = k - d - 1 \). Substituting eqs. (5.5), (5.6) in (5.2) and imposing the projection \( \Gamma_0^1\rho\Psi = -\Psi \), we are led to the following first-order equation of motion

\[
\left\{ \left(\frac{R}{r}\right)^3 \Gamma^\mu\partial_\mu + \left(\frac{r}{R}\right)^3 \Gamma^\rho\partial_\rho \pm \frac{1}{R^2} \left(\frac{3}{4} \frac{\rho}{\sqrt{r}} + \frac{m r^2}{2 \rho}\right) \right\} \Psi^{\ell\pm} = 0 .
\]

(5.7)

In what follows we consider that \( \sum_i (w^i)^2 = L^2 \), which by its turn leads to \( r^2 = \rho^2 + L^2 \). In both cases, \( L \) constitutes the distance between the D1- and the Dk-branes. Applying the procedure which was described in section 4 to eq. (5.7), we construct the following second-order differential equation

\[
\left(\mathcal{A}_1^\pm \partial_\rho^2 + \mathcal{A}_2^\pm \partial_\rho + \mathcal{A}_3^\pm \bar{M}^2 + \mathcal{A}_4^\pm \Gamma^0 + \mathcal{A}_5^\pm \right) \psi^{\ell\pm} (\varrho) = 0 ,
\]

where

\[
\mathcal{A}_1^\pm = 1 , \quad \mathcal{A}_2^\pm = \frac{m}{\varrho} + \frac{9}{2} \frac{\varrho}{\varrho^2 + 1} , \quad \mathcal{A}_3^\pm = \frac{1}{(\varrho^2 + 1)^2} ,
\]

\[
\mathcal{A}_4^\pm = \frac{3}{2} \frac{\lambda + \sqrt{\lambda^2 + m^2}}{\varrho^2 + 1} + \frac{1}{\varrho^2} \left(\lambda + \frac{m}{2}\right) + \frac{3}{2} \frac{\varrho^2}{(\varrho^2 + 1)^2} ,
\]

\[
\mathcal{A}_5^\pm = \frac{3}{4} \frac{1}{\varrho^2 + 1} (3m^2 + 2m + 1 + 4\lambda) - \frac{15}{16} \frac{\varrho^2}{(\varrho^2 + 1)^2} - \frac{1}{\varrho^2} \left(\lambda^2 + m\lambda + \frac{m}{2}\right) .
\]
Employing the projection $\Gamma^\rho \psi^{\ell \pm} = \psi^{\ell \pm}$ and adopting the same notation as in section 3 we are led to

$$\left[ \partial_e^2 + \left( \frac{m}{\varrho} + \frac{9}{2} \frac{\varrho}{\varrho^2 + 1} \right) \partial_{\varrho} + \frac{\bar{M}^2}{(\varrho^2 + 1)^3} - \frac{1}{\varrho^2} \left( \ell^2 + (m + 1)\ell + m \right) \right. $$
$$\left. + \frac{9}{4} \frac{1 + m}{\varrho^2 + 1} + \frac{9}{16} \frac{\varrho^2}{(\varrho^2 + 1)^2} \right] \psi^G_{\ell}(\varrho) = 0, \quad (5.10)$$

for positive and negative spinorial harmonics, respectively. As we already mentioned, $m = k - d - 1$, which by its turn implies that for $k = 5$ we have $m = 3$, while for $k = 3$ we have $m = 2$. The corresponding bosonic equations of motion for the D1/D5 and D1/D3-brane systems can be determined from eqs. (C.2) and (C.3), respectively. Hence, setting $p = 1$ in the aforementioned relations, we get

$$\left[ \partial_e^2 + \left( \frac{m}{\varrho} + \frac{9}{2} \frac{\varrho}{\varrho^2 + 1} \right) \partial_{\varrho} + \frac{\bar{M}^2}{(\varrho^2 + 1)^3} - \frac{1}{\varrho^2} \left( \ell^2 + (m - 1)\ell \right) \right. $$
$$\left. + \frac{9}{4} \frac{1 + m}{\varrho^2 + 1} + \frac{9}{16} \frac{\varrho^2}{(\varrho^2 + 1)^2} \right] \psi^F_{\ell}(\varrho) = 0, \quad (5.11)$$

respectively. One can easily verify that the transformation

$$\psi^G_{\ell}(\varrho) = \frac{1}{(1 + \varrho^2)^{9/8}} f_{\ell + 1}(\varrho), \quad (5.14)$$

maps eq. (5.10) either to eq. (5.12), when we have the D1/D5 setup, or to eq. (5.13), when we have the D1/D3 setup. In exactly the same sense, the transformation

$$\psi^F_{\ell}(\varrho) = \frac{1}{(1 + \varrho^2)^{9/8}} f_{\ell}(\varrho), \quad (5.15)$$

maps eq. (5.11) either to eq. (5.12) (D1/D5 setup), or to eq. (5.13) (D1/D3 setup). The differential equations which result from (5.8) with the projection $\Gamma^\rho \psi^{\ell \pm} = -\psi^{\ell \pm}$, namely the differential equations for the $\psi^\ominus$ spinor, cannot be mapped to the corresponding bosonic equations of motion, although they provide us with the same mass eigenvalues $\bar{M}$. The reason behind this is the degeneracy which results from the projection matrix $\Gamma^\rho$. Notice as well that the above transformations can be obtained from (1.1) by setting $p = 1$.

The above equations of motion cannot be solved analytically (as in the case of bosonic mesons) and we have to resort to numerical analysis. We show explicitly the first few numerical values of the masses in Table 4. The numerical values for $n$ and $\ell$ describe the $F$ operators and one needs to shift appropriately the $\ell$ to read off the value of the $G$ states.
Table 4. Numerical results of the parameter $\bar{M}^2$ for the D1/D$k$ brane intersections. The left table pertains to the D1/D5 and the right one depicts results for the D1/D3 brane intersection.

| $\ell$ |  $n$ | 0 | 1 | 2 | 3 |
|-------|------|---|---|---|---|

6 Open-string fluctuations in the D2-background

The D2-background has been extensively studied in the past in the probe-limit [20] as well as beyond the quenched approximation [41]. The relevant orientation of the branes in order for the boundary theory to preserve eight supercharges is shown in Table 5.

The fermionic action is given by [24–26]

$$S_{Dk} = \frac{T_{Dk}}{2} \int d^{k+1}\xi \sqrt{-\tilde{g}} \tilde{\Psi} \left( \bar{\Psi}_{Dk} + \frac{e^\phi}{8 \cdot 4!} F_{ABCD} \left( \Gamma^{ABC} - \Gamma^M \Gamma^{ABC} \Gamma_M \right) - \frac{1}{2} \partial^M \phi \right) \Psi. \tag{6.1}$$

Varying eq. (6.1) with respect to the conjugate spinor $\bar{\Psi}$, we readily obtain the equation of motion of the spinor $\Psi$, namely it is

$$\bar{D}_{Dk} \Psi + \frac{e^\phi}{8 \cdot 4!} F_{ABCD} \left( \Gamma^{ABC} - \Gamma^M \Gamma^{ABC} \Gamma_M \right) \Psi - \frac{1}{2} \partial^M \phi \Psi = 0, \tag{6.2}$$

where the dilaton field and the R-R field strength, which in this case constitutes a 4-form, can be determined from eq. (2.6) with $p = 2$, thus we have

$$e^\phi = \left( \frac{R}{r} \right)^{\frac{k}{2}}, \tag{6.3}$$

$$F_{(4)} = dC_{(3)} = -\frac{5 \sqrt{r}}{R^{5/2}} e^{(0)} \wedge e^{(1)} \wedge e^{(2)} \wedge \left( \rho e^{(\rho)} + \sum_{i=1}^{7-k+d} w_i e^{(w_i)} \right), \tag{6.4}$$

respectively. As it is depicted in Table 5, there are three possibilities for the probe D$k$-branes, $k = \{2, 4, 6\}$ with $d = \{0, 1, 2\}$ respectively. Having in our disposal the components
of the R-R field strength as well as the expression of the dilaton field it is straightforward to calculate that
\[
\frac{e^\phi}{8 \cdot 4!} F_{ABCD} \left( \Gamma^{ABCD} - \Gamma^M \Gamma^{ABCD} \Gamma_M \right) \Psi = \frac{5}{4} \frac{\rho}{R^{5/4} r^{3/4}} \Gamma_{012\rho} \Psi ,
\]
while by setting \( p = 2 \) in eqs. (4.3) we get
\[
\Phi_{Dk} \Psi^{\ell \pm} - \frac{\Gamma^M \partial_M \Phi}{2} \Psi^{\ell \pm} = \left( \frac{R}{r} \right)^{\frac{\ell}{2}} \Gamma^\mu \partial_\mu \Psi^{\ell \pm} + \left( \frac{r}{R} \right)^{\frac{\ell}{2}} \Gamma^\rho \partial_\rho \Psi^{\ell \pm} \pm \frac{1}{\rho} \left( \frac{r}{R} \right)^{\frac{\ell}{2}} \left( \ell + \frac{m}{2} \right) \Psi^{\ell \pm} 
+ \frac{1}{R^2} \left( \frac{5 \rho}{8 r^{\frac{3}{2}}} + \frac{m r^{\frac{5}{2}}}{2 \rho} \right) \Gamma^\rho \Psi^{\ell \pm}.
\]

Substituting eqs. (6.5), (6.6) in (6.2) and imposing the projection \( \Gamma_{012\rho} \Psi = \Psi \), we are led to the following first-order equation of motion
\[
\left\{ \left( \frac{R}{r} \right)^{\frac{\ell}{2}} \Gamma^\mu \partial_\mu + \left( \frac{r}{R} \right)^{\frac{\ell}{2}} \Gamma^\rho \partial_\rho + \frac{1}{R^2} \left[ \frac{5 \rho}{4 r^{\frac{3}{2}}} \pm \left( \ell + \frac{m}{2} \right) \frac{r^{\frac{5}{2}}}{\rho} \right] + \frac{1}{R^2} \left( \frac{5 \rho}{8 r^{\frac{3}{2}}} + \frac{m r^{\frac{5}{2}}}{2 \rho} \right) \Gamma^\rho \right\} \Psi^{\ell \pm} = 0.
\]

Applying the procedure which was described in section 4 to eq. (6.7), we construct the following second-order differential equation
\[
\left( A_1^\pm \partial_\rho^2 + A_2^\pm \partial_\rho + A_3^\pm M^2 + A_4^\pm \Gamma^\rho + A_5^\pm \right) \psi^{\ell \pm}_i (\rho) = 0,
\]
where
\[
A_1^\pm = 1, \quad A_2^\pm = \frac{m}{\varrho} + \frac{15}{4} \frac{\varrho}{\varrho^2 + 1}, \quad A_3^\pm = \frac{1}{(\varrho^2 + 1)^{5/2}},
\]
\[
A_4^\pm = \frac{5}{4} \frac{1 + 2 \ell \pm m}{\varrho^2 + 1} \mp \frac{1}{\varrho^2} \left( \ell + \frac{m}{2} \right) + \frac{5}{8} \left( \varrho^2 + 1 \right)^{5/2},
\]
\[
A_5^\pm = \frac{5}{8} \frac{1}{\varrho^2 + 1} \left( 3m \mp 2m + 1 \mp 4\ell \pm \frac{55}{64} \frac{\varrho^2}{(\varrho^2 + 1)^2} \right) - \frac{1}{\varrho^2} \left( \ell^2 + m\ell + \frac{m}{2} \right).
\]

Employing the projection \( \Gamma^\rho \psi^{\ell \pm} = \psi^{\ell \pm} \) and using eqs. (6.8) and (6.9) one can readily obtain the fermionic second-order ordinary differential equation for \( \psi^{\ell \pm}_i (\rho) \). In case of positive spinorial harmonics (\( \ell^+ \)), we get the differential equation of \( \psi^{\ell \pm}_i (\rho) \), while for negative spinorial harmonics (\( \ell^- \)), the differential equation of \( \psi^{\ell \pm}_i (\rho) \) is obtained. The corresponding bosonic equations of motion for the D2/Dk-brane setups (\( k = \{2, 4, 6\} \)), can be determined from eqs. (C.2)–(C.4) by setting \( p = 2 \). For all possible D2/Dk-brane systems the transformation
\[
\psi^{\ell \pm}_i (\rho) = \frac{1}{(1 + \varrho^2)^{15/16}} f_{\ell + 1}(\rho),
\]
maps the fermionic function \( \psi^{\ell \pm}_i (\rho) \) to the bosonic function \( f_{\ell + 1}(\rho) \), while the transformation
\[
\psi^{\ell \pm}_i (\rho) = \frac{1}{(1 + \varrho^2)^{15/16}} f_{\ell}(\rho),
\]
maps the fermionic function $\psi_{\mathcal{F}_\ell}(\varrho)$ to the bosonic function $f_{\ell}(\varrho)$. Notice as well that the above transformations can be obtained from (1.1) by setting $p = 2$.

The above equations of motion cannot be solved analytically (as in the case of bosonic mesons). We show explicitly the first few numerical values of the masses in Table 6. The numerical values for $n$ and $\ell$ describe the $\mathcal{F}$ operators and one needs to shift appropriately the $\ell$ to read off the value of the $\mathcal{G}$ states. It is important to stress at this point that, in cases where the dimensionality of the background and the probe brane is the same, the quantum number $\ell$ — contrary to the rest of the cases — should be greater than zero as dictated by the normalizability of the mode solution in the UV; observe for example the bottom table in Table 6.

### Table 6. Numerical results of the parameter $\tilde{M}^2$ for the D2/D$k$ brane intersections. The top left table pertains to the D2/D6 and the top right one depicts results for the D2/D4 brane intersection. The bottom table is related to the D2/D2 setup.

| $n$ | 0  | 1  | 2  | 3  |
|-----|----|----|----|----|
| $\ell$ | 0  | 11.509 | 37.185 | 76.982 | 130.93 |
| 1   | 33.403 | 70.149 | 121.15 | 185.66 |
| 2   | 66.197 | 114.96 | 177.34 | 253.38 |
| 3   | 109.75 | 170.30 | 244.10 | 332.17 |

| $n$ | 0  | 1  | 2  | 3  |
|-----|----|----|----|----|
| $\ell$ | 0  | 4.9024 | 25.519 | 60.595 | 110.03 |
| 1   | 21.065 | 52.295 | 97.385 | 156.40 |
| 2   | 48.453 | 91.334 | 147.86 | 218.09 |
| 3   | 86.630 | 141.29 | 209.54 | 291.40 |

| $n$ | 0  | 1  | 2  | 3  |
|-----|----|----|----|----|
| $\ell$ | 1  | 11.509 | 37.185 | 76.982 | 130.93 |
| 2   | 33.403 | 70.149 | 121.15 | 185.66 |
| 3   | 66.197 | 114.96 | 177.34 | 253.38 |

7 Probing the D3-background

Before we start the analysis of the fermionic modes for the background generated by a stack of $N_c$ branes we would like to illustrate the brane intersections that we examine in this work. This is shown in Table 7.

The fermionic action in the D3-brane background is \[ \mathcal{S}_{D3} = \frac{T_{D3}}{2} \int d^{k+1}x \sqrt{-g} \bar{\Psi} \Gamma^M F_{ABCDE} \Gamma^M \Gamma_M \Psi. \] (7.1)

Varying eq. (7.1) with respect to the conjugate spinor $\bar{\Psi}$, we readily obtain the equation of motion of the spinor $\Psi$, namely it is

\[ D_{D3} \Psi + \frac{i}{2 \cdot 8 \cdot 5!} \Gamma^M F_{ABCDE} \Gamma^M \Gamma_M \Psi = 0. \] (7.2)
In case of the D7-brane setup, it is straightforward to calculate that

\[ F_{(5)} = dC(4) + *(dC(4)). \]  

(7.3)

As it is depicted in Table 7, there are three possibilities for the probe Dk-branes, \( k = \{3, 5, 7\} \) with \( d = \{1, 2, 3\} \) respectively. In case of the D3/D3-brane setup, the above relation leads to

\[ F_{(5)} = \frac{4}{rR} \left[ e^{(0)} e^{(1)} e^{(2)} e^{(3)} \left( \rho e^{(\rho)} + \sum_{m=1}^{4} w^m e^{(w^m)} \right) - \rho e^{(\theta)} e^{(w^1)} e^{(w^2)} e^{(w^3)} e^{(w^4)} - e^{(\theta)} e^{(w^1)} e^{(w^2)} e^{(w^3)} e^{(w^4)} - w^4 e^{(w^1)} e^{(w^2)} e^{(w^3)} \right] . \]  

(7.4)

In case of the D3/D5-brane setup, it is

\[ F_{(5)} = \frac{4}{rR} \left[ e^{(0)} e^{(1)} e^{(2)} e^{(3)} \left( \rho e^{(\rho)} + \sum_{m=1}^{3} w^m e^{(w^m)} \right) - \rho e^{(S^2)} e^{(w^1)} e^{(w^2)} e^{(w^3)} + e^{(\rho)} e^{(S^2)} e^{(w^1)} e^{(w^2)} - w^1 e^{(w^2)} e^{(w^3)} - w^2 e^{(w^1)} e^{(w^3)} + w^3 e^{(w^1)} e^{(w^2)} \right] , \]  

(7.5)

where \( e^{(S^2)} = e^{(\theta_1)} e^{(\theta_2)} \). Finally, in case of the D3/D7-brane setup, we have

\[ F_{(5)} = \frac{4}{rR} \left[ e^{(0)} e^{(1)} e^{(2)} e^{(3)} \left( \rho e^{(\rho)} + \sum_{m=1}^{2} w^m e^{(w^m)} \right) - \rho e^{(S^3)} e^{(w^1)} e^{(w^2)} - e^{(\rho)} e^{(S^3)} \left( w^1 e^{(w^2)} - w^2 e^{(w^1)} \right) \right] , \]  

(7.6)

where \( e^{(S^3)} = e^{(\theta_1)} e^{(\theta_2)} e^{(\theta_3)} \). Having in our disposal the components of the R-R field strength as well as the expression of the dilaton field it is straightforward to calculate that

\footnotetext{For more details about the Hodge star operator see appendix A.}
regardless the D3/Dk-brane system it is

\[
\frac{i}{2 \cdot 8 \cdot 5!} \Gamma^M F_{ABCDEFG} \Gamma^{ABCDEFG} \Gamma_M \Psi = 2 \Gamma_0 1234 \Psi, 
\]  

(7.7)

while by setting \(p = 3\) in (4.3) we get

\[
\mathcal{D}_{DK} \Psi^{\pm} \Gamma^M \frac{\partial M \Phi}{2} \Psi^{\pm} = \left\{ \frac{R}{r} \Gamma^\mu \partial_\mu + r \Gamma^\rho \partial_\rho \pm \frac{1}{\rho} \frac{r}{2} \left( \ell + m \frac{r}{2} \right) \Gamma^\rho \right\} \Psi^{\pm}. 
\]

(7.8)

Substituting eqs. (7.7), (7.8) in (7.2) and imposing the projection \(\Gamma_0 \Psi = -i \Psi\), we are led to the following first-order equation of motion

\[
\left\{ \frac{R}{r} \Gamma^\mu \partial_\mu + r \Gamma^\rho \partial_\rho + \frac{1}{2 \rho} \left( \ell + m \frac{r}{2} \right) \Gamma^\rho \right\} \Psi^{\pm} = 0. 
\]

(7.9)

Applying the procedure which was described in section 4 to eq. (7.9), we construct the following second-order differential equation

\[
\left( A^1_+ \partial_\phi^2 + A^2_+ \partial_\phi + A^3_+ \tilde{M}^2 + A^4_+ \Gamma^\rho + A^5_+ \right) \psi^{\pm}(\phi) = 0, 
\]

(7.10)

where

\[
A^1_+ = 1, \quad A^2_+ = \frac{m}{\rho} + \frac{3}{\rho^2 + 1}, \quad A^3_+ = \frac{1}{(\rho^2 + 1)^2}, 
\]

\[
A^4_+ = \frac{1}{\rho^2 + 1} - \frac{1}{\rho^2} \left( \ell + m \frac{r}{2} \right), 
\]

\[
A^5_+ = \frac{1}{\rho^2 + 1} \left( \frac{3m + 1 + 2m}{2} \pm 2\ell \right) - \frac{3}{4 (\rho^2 + 1)^2} - \frac{1}{\rho^2} \left( \ell^2 + m \ell + \frac{m^2}{2} \right). 
\]

(7.11)

Employing the projection \(\Gamma^\rho \psi^{\pm} = \psi^{\pm}\) and using eqs. (7.10) and (7.11) one can readily obtain the fermionic second-order ordinary differential equation for \(\psi^{\pm}(\phi)\). In case of positive spinorial harmonics (\(\ell^+\)), we get the differential equation of \(\psi^G_{\ell^+}(\phi)\), while for negative spinorial harmonics (\(\ell^-\)), the differential equation of \(\psi^F_{\ell^-}(\phi)\) is obtained. The corresponding bosonic equations of motion for the D3/Dk-brane setups \((k = \{3, 5, 7\})\), can be determined from eqs. (C.2)–(C.4) by setting \(p = 3\). For all possible D3/Dk-brane systems the transformation

\[
\psi^{G}_{\ell+}(\phi) = \frac{1}{(1 + \rho^2)^{3/4}} f_{\ell+1}(\phi), 
\]

(7.12)

maps the fermionic function \(\psi^{G}_{\ell+}(\phi)\) to the bosonic function \(f_{\ell+1}(\phi)\), while the transformation

\[
\psi^{G}_{\ell-}(\phi) = \frac{1}{(1 + \rho^2)^{3/4}} f_{\ell}(\phi), 
\]

(7.13)

maps the fermionic function \(\psi^{G}_{\ell-}(\phi)\) to the bosonic function \(f_{\ell}(\phi)\). Notice as well that the above transformations can be obtained from (1.1) by setting \(p = 3\).
7.1 Analytic solutions

The equation of motion which result from (7.11) admit analytic solutions. Although they have been previously derived in [29, 32] for massless and massive flavours respectively, we present them here as well for completeness. The solution of the differential equation related to the positive spinor spherical harmonics is of the following form

\[
\psi_G = \frac{\varrho^{\ell+1}}{(1 + \varrho^2)^{(n + \ell + \frac{m}{2} + \frac{1}{2})}} \, 2F1\left(-n, -n - \ell - \frac{1}{2}(m + 1); \ell + \frac{m + 3}{2}; -\varrho^2\right) \chi^+ \\
+ \frac{\varrho^{\ell}}{(1 + \varrho^2)^{(n + \ell + \frac{m}{2} + \frac{1}{2})}} \, 2F1\left(-n, -n - \ell - \frac{1}{2}(m + 3); \ell + \frac{m + 1}{2}; -\varrho^2\right) \chi^-.
\]  

(7.14)

In the above, the number \(n\) is directly related to the mass spectrum via the relation

\[
\bar{M}^2_G = 4 \left(n + \ell + \frac{m + 1}{2}\right) \left(n + \ell + \frac{m + 3}{2}\right),
\]  

(7.15)

where \(n, \ell \geq 0\). The spinors \(\chi^\pm\) are eigenstates of the \(\Gamma^{\varrho}\)-matrix and they obey the relation

\[
\Gamma^{\varrho} \chi^\pm = \pm \chi^\pm.
\]

(7.16)

We can perform the same analysis and derive the solutions describing the \(\mathcal{F}\), the ones obtained by considering the negative eigenvalues on the internal manifold. They are

\[
\psi_F = \frac{\varrho^{\ell}}{(1 + \varrho^2)^{(n + \ell + \frac{m}{2} + \frac{1}{2})}} \, 2F1\left(-n, -n - \ell - \frac{1}{2}(m - 1); \ell + \frac{m + 1}{2}; -\varrho^2\right) \chi^+ \\
+ \frac{\varrho^{\ell+1}}{(1 + \varrho^2)^{(n + \ell + \frac{m}{2} + \frac{1}{2})}} \, 2F1\left(-n, -n - \ell - \frac{1}{2}(m + 1); \ell + \frac{m + 3}{2}; -\varrho^2\right) \chi^-.
\]  

(7.18)

leading to the discrete mass spectrum

\[
\bar{M}^2_F = 4 \left(n + \ell + \frac{m - 1}{2}\right) \left(n + \ell + \frac{m + 1}{2}\right),
\]  

(7.19)

\(n, \ell \geq 0\). The asymptotic behaviour of the above solution in the UV (\(\varrho \to \infty\)) and the IR (\(\varrho \to 0\)) are given below

\[
\psi_G|_{\varrho \to \infty} \sim \varrho^{-\ell-m-3/2} \chi^+ + \varrho^{-\ell-m-5/2} \chi^-,
\]

\[
\psi_G|_{\varrho \to 0} \sim \varrho^{\ell+1} \chi^+ + \varrho^{\ell} \chi^-.
\]

(7.17)
7.2 Baryons and the large-$N_c$ limit

In this section we would like to specify our discussion to the case of a four-dimensional strongly coupled gauge theory without defects and hence we will be focused on the D3/probe-D7 intersection. The extension of the analysis to lower dimensional gauge theories based on the D3-background geometry is straightforward and similar arguments can be given for theories with quarks confined on one and two-dimensional defects.

We have studied, thus far, the dynamics and solved for the spectra of the fermionic superpartners of mesons — dubbed mesinos — which have no counterpart in ordinary non-supersymmetric field theories. For phenomenological applications of holography, however, it is interesting to study fermionic degrees of freedom in the bulk. As it was pointed out in [32] a certain class of these mesino states, namely the $\mathcal{G}$ string modes, resemble structurally the baryons of ordinary QCD. This observation was made at the level of the analysis of the fluctuation to operator matching. It was observed that these states are comprised out of three elementary fermionic fields, two quarks and a gaugino.

On the formal side of the analysis, the true dynamical baryonic vertex in the string theory setup has been described in [38] and it consists of our base system with the D7-probe in addition to which we add D5-branes wrapping a spherical subspace inside the initial $AdS_5 \times S^5$ background geometry and having $N_c$ strings ending on it. One can immediately see the complications. Since in the dynamical baryonic vertex $N_c$ strings are ending on the baryonic (D5-)brane it is unclear whether or not the probe-approximation can be made and what its regime of validity is if any. Also, since the brane intersection consists of several different branes, the topology of the system of interest is inherently complicated. Finally, baryons are half-integer fields and their dynamics are governed by the Dirac or the Rarita-Schwinger actions which have to be studied on highly curved manifolds.

Now, we would like to give additional evidence and support the notion that the $\mathcal{G}$-states (which we remind the reader are $\mathcal{G} \sim \bar{\psi} \lambda \psi$, where $\bar{\psi}, \psi$ are fundamental Fermi fields — quark like states — and $\lambda$ is an adjoint fermion — a gaugino field) can be thought of as effectively describing baryonic operators. In order to amplify and re-express the argument of [32] regarding the possible baryonic interpretation of these supergravity states, we will show that their mass eigenvalues obey the correct large-$N_c$ scaling, dictated by field theory considerations [36]. This has already been done in an effective, bottom-up approach in [29]. More precisely the case of massless quarks/overlapping branes was considered in that work.

We start the analysis of this section by recalling that the scaling dimension and the $AdS_5$ mass for a spin-1/2 field is given by [42]

$$\Delta_\ell = |m_\ell| + 2,$$

and for the states considered so far we have $m_\ell^\mathcal{G} = \ell_2 + \ell$ and $m_\ell^\mathcal{F} = -\left(\frac{1}{2} + \ell\right)$ for the $\mathcal{G}$ and $\mathcal{F}$ states respectively.

Now, let us turn our attention to baryonic operators in a supersymmetric Yang-Mills theory with an $SU(N_c)$ gauge group and a certain number of flavours. We will be assuming that the theory is such that it is conformal, or perhaps more generally it possesses a regime in its phase space with walking dynamics (conformal window). There are many examples
of such four-dimensional field theories that are asymptotically free, for a discussion on the phase diagram of supersymmetric $SU(N_c)$ Yang-Mills theories see [43], but here we just mention the four-dimensional $SU(3)$ super-QCD with $9/2 \leq N_f \leq 9$ flavours as an example of the theories we mentioned. The existence of the conformal phase of the theory makes sure that the holographic gravity description has an $AdS_5$ structure. In the aforementioned class of theories a baryon is the colour singlet composite bound state comprised out of $N_c$ quarks, and a baryonic operator is the totally anti-symmetrized object given by

$$B \sim \epsilon^{ijk \cdots yz} \underbrace{q_i q_j q_k \cdots q_y q_z}_{N_c-fields}, \quad (7.22)$$

where we have written the lowest entry of the super(conformal) multiplet up to an irrelevant numerical coefficient which is a function of $N_c$. We can construct higher baryonic excitations in the multiplet by applying an $\ell$ number of times the derivative operator to the above. The associated conformal dimension is given by

$$\Delta = \frac{3}{2} N_c + \ell. \quad (7.23)$$

It is straightforward to use (7.21) and obtain

$$m_{B}^{\ell} = \frac{3}{2} N_c + \ell - 2. \quad (7.24)$$

We have already seen that the positive spinor spherical harmonics give rise to states that resemble baryons of non-supersymmetric QCD. We re-write the eigenvalues of the spinor spherical harmonic in a different but equivalent form for the $G$-modes

$$D_{S^3} \Psi^{\ell+} = \left( m_{Q}^{\ell} - 1 \right) \Psi^{\ell+}. \quad (7.25)$$

At this point we replace in the above relation eq. (7.25) the bulk-AdS mass for a baryonic operator given by eq. (7.24) and hence we obtain

$$D_{S^3} \Psi = \left( m_{B}^{\ell} - 1 \right) \Psi. \quad (7.26)$$

It is a matter of simple algebra to derive the differential equation by using eq. (7.26) and the mathematical procedure explained in the previous section. Thus, we get

$$\left\{ \partial_{\varphi}^{2} + \left[ \frac{3 \varphi}{1 + \varphi^2} + \frac{2(m_{B}^{\ell} - \ell - 1)}{\varphi} \right] \partial_{\varphi} + \frac{\hat{M}_B^2}{(1+\varphi^2)^2} - \frac{3}{4} \varphi^2 \left[ \frac{1}{\varphi^2} \left[ m_{B}^{\ell}(2\ell+1) - (\ell+1)^2 - \ell \right] + (m_{Q}^{\ell} - 1) \Gamma^\varphi \right] + \frac{1}{1 + \varphi^2} \left[ m_{B}^{\ell} - 3\ell - \frac{1}{2} + (2m_{B}^{\ell} - 1) \Gamma^\varphi \right] \right\} \Psi = 0. \quad (7.27)$$

In order to obtain the solution to the above equation of motion representing the supergravity states we require the solution to be normalizable in the UV and regular in the IR,
hence, we have

\[
\psi_B = \frac{\varrho^{\ell+1}}{(1+\varrho^2)^{n+\ell+\frac{3N_c}{2}-\frac{5}{2}}} \, _2F_1\left(-n,-n-\ell-\frac{3N_c-5}{2};\ell+\frac{3(N_c-1)}{2};-\varrho^2\right) \chi_+ + \frac{\varrho^{\frac{9}{2}+\ell+\frac{3N_c}{2}}}{(1+\varrho^2)^{-\frac{1}{2}+n+\ell+\frac{3N_c}{2}}} \, _2F_1\left(-n,-n-\ell-\frac{3(N_c-1)}{2};\ell+\frac{3N_c-5}{2};-\varrho^2\right) \chi_-, \tag{7.28}
\]

while the discrete mass spectrum is shown below

\[
\bar{M}_B = 2 \sqrt{\left(n + \ell + \frac{3N_c}{2} - \frac{5}{2}\right) \left(n + \ell + \frac{3}{2}(N_c-1)\right)}. \tag{7.29}
\]

It is obvious that in the \(N_c \to \infty\) limit the mass scales with \(N_c\) as desired [36]. It is quite obvious as well, that for \(N_c = 3\) eqs. (7.28) and (7.29) reduce to the ones derived in section 7.1 above for the D3/probe-D7 setup.

Let us conclude the discussion of this section by stating the basic points. The large-\(N_c\) limit scaling of the mass was derived in [29] for the case of overlapping branes in a bottom-up way effectively. Here, we provide a derivation from the top-down construction in a set-up that describes massive dynamical quarks by construction. We should stress — though obvious — that our result is derived by assuming that the identification of the \(G\) modes as describing baryonic operators at least in some regime of the parameter space of the gauge theory is correct. The precise statement we wish to make here is the same as the one made in [29]. If one realizes and manages to solve the brane configuration that yields a dynamical baryon in the string theory side with an AdS geometric part, then the result derived in eq. (7.29) should be re-obtained from the full brane intersection; it should at least hold in a certain regime of the parameter space of the full setup.

### 7.3 Double-trace boundary interactions and avoided level crossings

The models that we have considered thus far cannot give rise to abnormally light fermionic states compared to the scale set by the vector meson mass of the brane intersection. The reason behind this, lies to the residual amount of supersymmetry — after the introduction of flavour branes — which ties these masses to the spectra of the bosonic meson states. It is, however, useful for applications of holographic models to understand if and how one is able to make certain states lighter. A neat example is the study of holographic composite Higgs models [44] where the double-trace interactions are necessary to ensure the correct mass for the top. Double-trace deformations are also used in other bottom-up applications in holography. They have been used, for example, to describe the colour superconductivity [45] where the double-trace interactions are used to generate the Cooper pair condensate.

With holographic applications in mind, the authors in [32] considered double-trace deformations of the boundary Lagrangian of “mesino” squared type. The way that this was achieved was to use the prescription for higher dimensional operators described by Witten [34]. The addition of such operators is naively a reduction to the fermionic mass
in the low-energy hadronic description. It is worthwhile mentioning that the method with
the double-trace interactions has been used in the past in the context of the D3/probe-D7
brane intersection to describe the Nambu-Jona-Lasinio model [46]. This model utilizes
four-fermi interactions.

The precept of the exercise with double-trace operators of “mesino” squared type is
that any state can be driven much lighter compared to the undeformed $\mathcal{N} = 2$ theory,
however it can never be made lighter than the previous one in the supermultiplet. Hence,
the authors in [32] found an avoided level-crossing. This was observed only numerically
and an analytic explanation is still lacking. Here we provide an analytic explanation.

The effects of adding these higher dimension operators should manifest themselves as
new phenomena at some scale in the UV which we call $\Lambda_{UV}$. These operators deform
the original Lagrangian in the following schematic way:

$$\mathcal{L} + \frac{g^2}{\Lambda_{UV}^q} \bar{O} O,$$

(7.30)

where the power $q$ is chosen with relevance to the conformal dimension of the operator.
Witten argued that if the operator obtains a non-trivial vacuum expectation value, it
generates a source at the UV boundary, which is given by

$$\mathcal{J} = \frac{g^2}{\Lambda_{UV}^q} \langle O \rangle.$$

(7.31)

All the spectra presented so far, and the spectra that we present in section 8 for the D4
background, are solutions with a vanishing source; $\mathcal{J} = 0$. In order to include the double-
trace deformation of the Lagrangian, we allow for solutions to have $\mathcal{J} \neq 0$, and from the
asymptotic expansions of these modes in the UV we can read off the precise values of $O$ and
$\mathcal{J}$. The asymptotic expansions have been obtained in the past and the precise explanation
of the sources and operators in terms of these expansions are given in [32, 35] and we do
not repeat the analysis here. Then, by using eq. (7.31) we are able to obtain the coupling
$g^2$. These new solutions that have $\mathcal{J} \neq 0$ are interpreted as being part of the sourceless
theory in the presence of the higher dimensional operators.

Having explained the way that these higher dimensional operators can be included in
our base system, let us focus, without loss of generality, on the D3/D7 brane junction and
the modes associated to the $\mathcal{G}$ operators. For a certain value of the angular momentum
$\ell = 0$ we ask the question whether or not the first radially excited state of the KK tower,
$n = 1$, can be driven lighter than the ground state, $n = 0$. There is numerical evidence
that this does not happen.

Since we have already argued that the same arguments can be obtained from either
of the $\Gamma^\varphi$ projections we will be using the $\oplus$ states for convenience. Under the change of
variables:

$$\varphi = e^{-y}, \quad \psi(\varphi) = \frac{e^{-2y}}{(1 + e^{2y})^{3/4}} \varphi(y),$$

(7.32)

the equations of motion can be brought in a Schrödinger form, namely

$$(\partial_y^2 - V(y)) \varphi(y) = 0,$$

(7.33)
with the potential being given by:
\[ V(y) = (\ell + 2)^2 - \frac{1}{4} \sech^2 y \tilde{M}^2. \]  
(7.34)

We drop the explicit \( y \)-dependence for notational convenience and we denote the ground state \((n = 0, \ell = 0)\) by \( \varphi_0 \) and the corresponding mass eigenvalue by \( M_0^2 \). Likewise we use the subscript \( 1 \) for the \( n = 1, \ell = 0 \) state or any state that lies above the ground state \((n > 0, \ell = 0)\) of the system and has a higher mass with a non-vanishing source in the UV. Hence, we obtain
\[
\frac{\partial^2 y}{\partial y^2} \varphi_0 - V_0 \varphi_0 = 0, \\
\frac{\partial^2 y}{\partial y^2} \varphi_1 - V_1 \varphi_1 = 0.
\]
(7.35)

If a level-crossing is to occur it would mean that \( \tilde{M}_0^2 = \tilde{M}_1^2 \) (and \( V_0 = V_1 \)) for some value of a specified source term. We multiply the first equation by \( \varphi_1 \) and the second by \( \varphi_0 \) and we subtract one from the other to obtain
\[
\varphi_1 \frac{\partial^2 y}{\partial y^2} \varphi_0 - \varphi_0 \frac{\partial^2 y}{\partial y^2} \varphi_1 = 0 \Rightarrow \\
\frac{\partial y}{\partial y} (\varphi_1 \frac{\partial y}{\partial y} \varphi_0 - \varphi_0 \frac{\partial y}{\partial y} \varphi_1) = 0 \Rightarrow \\
\varphi_1 \frac{\partial y}{\partial y} \varphi_0 - \varphi_0 \frac{\partial y}{\partial y} \varphi_1 = c,
\]
(7.36)

where \( c \) is just a finite constant. Note that if we are dealing with the normalizable modes only, then we can use the boundary conditions at infinity to set \( c = 0 \) and we solve the differential equation above to obtain \( \varphi_0 = \tilde{c} \varphi_1 \), where now \( \tilde{c} \) is a new constant. However, this would only mean that there is no deformation of the boundary Lagrangian and we have only the states of the undeformed \( N = 2 \) theory. If we wish to allow for a non-negligible double-trace deformation we should formally write
\[
\varphi_1 \frac{\partial y}{\partial y} \varphi_0 - \varphi_0 \frac{\partial y}{\partial y} \varphi_1 = c,
\]
(7.37)

for some finite value of the constant \( c \). Note that while we know that \( \varphi_0 \) is the ground state and hence it falls off to 0 in the UV we cannot set the constant to \( c = 0 \) as the term with the non-vanishing source might be going to some finite value faster.

eq. (7.37) is a necessary condition for a level-crossing to occur, thus we can re-express it in terms of the \( \varrho \) coordinate and the spinorial wave-functions \( \psi_{(0,1)} \) in the following way:
\[
\varrho(1 + \varrho^2)^{3/2} \partial_\varrho \left[ \ln \left( \frac{\psi_0}{\psi_1} \right) \right] = \frac{c}{\psi_0 \psi_1}.
\]
(7.38)

We can readily obtain the form of \( \psi_0 \) by using eq. (7.14) for the special values \( n = \ell = 0, m = 3 \) and taking into account the positive \( \Gamma^e \)-projection, thus we get
\[
\psi_0 = \frac{\varrho}{(1 + \varrho^2)^{11/4}}.
\]
(7.39)

However, in order to obtain the form of \( \psi_1 \) we need to reconsider the solutions of the second-order equations of motion. The difference now is that we will allow as solutions the
more general form and not just the piece that falls off asymptotically to zero as $\varrho \to \infty$.

For our convenience we re-state the second-order differential equation of the $G$-modes for the positive $\Gamma^\rho$-projection:

$$\left[ \partial_\varrho^2 + \left( \frac{3}{\varrho} + \frac{3\varrho}{1+\varrho^2} \right) \partial_\varrho + \frac{M^2}{(1+\varrho^2)^2} - \left( \frac{3}{4} \frac{\varrho^2}{(1+\varrho^2)^2} + \frac{1}{\varrho^2}(\ell+1)(\ell+3) - \frac{6}{1+\varrho^2} \right) \right] \psi_G^{\rho_0}(\varrho) = 0.$$  \hfill (7.40)

The above admits analytic solutions -without any requirements as we did previously- which are given by:

$$\psi_G^{\rho_0}(\varrho) = (-)^{2\ell}(1+\varrho^2)^{-\frac{1}{4}+\frac{\sqrt{1+M^2}}{2}} \cdot 2F_1 \left( \frac{1}{2} + \frac{\sqrt{1+M^2}}{2}, -\frac{3}{2} - \ell + \frac{\sqrt{1+M^2}}{2}; -1+1; -\varrho^2 \right) + \varrho^{\ell+1}(1+\varrho^2)^{-\frac{1}{4}+\frac{\sqrt{1+M^2}}{2}} \cdot 2F_1 \left( \frac{1}{2} + \frac{\sqrt{1+M^2}}{2}, \frac{5}{2} + \ell + \frac{\sqrt{1+M^2}}{2}; \ell+3; -\varrho^2 \right).$$  \hfill (7.41)

Substituting $\psi_0$ from (7.39) and $\psi_1$ from (7.41) in the condition (7.38), and solving for $c$ we obtain an answer in terms of hypergeometric functions. When we fix $\ell = 0$ the solution for $c$ simplifies to complex infinity.

Similarly, one can ask the question of whether or not the ground state ($n = \ell = 0$) of the setup can be driven to be massless or even tachyonic. Again, numerical analysis in [32] has shown that this does not happen as it requires a double-trace deformation with infinitely strong coupling. The same conclusion that we reached previously can also be drawn for this example. The only change in the computation is that now the $n = \ell = 0$ state plays the role of $\psi_1$ in eq. (7.38) and the non-normalizable solution given by eq. (7.41) plays the role of the state with a zero mass.

Consequently, we argue that we found an analytic way to see why a level crossing does not occur in these systems and furthermore why the discontinuity in the double-trace plots appeared to be going to infinite values of the coupling.

8 The D4 background and five dimensional SYM theories

For illustrative purposes we show explicitly the relevant brane intersections in the case of the D4 background, see Table 8.

The fermionic action is given by [24–26]

$$S_{Dk} = \frac{T_{Dk}}{2} \int d^{k+1}x \sqrt{-g} \bar{\Psi} \mathcal{D}_k \left[ D_k \psi + \frac{e^\phi}{8 \cdot 4!} F_{ABCD} \left( \Gamma_{ABCD} - \Gamma_M^{\hat{M}} \Gamma_{ABCD} \Gamma_M^{\hat{M}} \right) - \frac{1}{2} \Gamma^M \partial_M \phi \right] \Psi. $$  \hfill (8.1)

Varying eq. (8.1) with respect to the conjugate spinor $\bar{\Psi}$, we readily obtain the equation of motion of the spinor $\Psi$, namely it is

$$\mathcal{D}_k \psi + \frac{e^\phi}{8 \cdot 4!} F_{ABCD} \left( \Gamma_{ABCD} - \Gamma_M^{\hat{M}} \Gamma_{ABCD} \Gamma_M^{\hat{M}} \right) \Psi - \frac{1}{2} \Gamma^M \partial_M \phi \Psi = 0,$$  \hfill (8.2)
where the dilaton field and the R-R field strength, which in this case constitutes a 4-form, can be determined from eq. (2.6) with \( p = 4 \), thus we have
\[
e^\phi = \left( \frac{r}{R} \right)^2, \quad F_4 = \ast (dC_3),
\] (8.3)
respectively. As it is depicted in Table 8, there are three possibilities for the probe Dk-branes, \( k = \{4, 6, 8\} \) with \( d = \{2, 4, 6\} \) respectively. In case of the D4/D4-brane setup, the above relation leads to
\[
F_4 = \frac{3}{r^2} \left[ \rho e^{(\theta)} \wedge e^{(w^1)} \wedge e^{(w^2)} + e^{(\rho)} \wedge (w^1 e^{(w^2)} + e^{(w^3)} - w^2 e^{(w^1)}) \right].
\] (8.4)
In case of the D4/D6-brane setup, it is
\[
F_4 = \frac{3}{r^2} \left[ \rho e^{(\theta)} \wedge e^{(w^1)} - e^{(\rho)} \wedge e^{(\theta)} + (w^1 e^{(w^2)} - w^2 e^{(w^1)}) \right],
\] (8.5)
where \( e^{(\theta)} = e^{(\theta_1)} \wedge e^{(\theta_2)} \). Finally, in case of the D4/D8-brane setup, we have
\[
F_4 = \frac{3}{r^2} \left[ \rho e^{(\theta)} \wedge e^{(w^1)} + w^1 e^{(\rho)} \wedge e^{(\theta)} \right],
\] (8.6)
where \( e^{(\theta)} = e^{(\theta_1)} \wedge e^{(\theta_2)} \wedge e^{(\theta_3)} \). Having in our disposal the components of the R-R field strength as well as the expression of the dilaton field it is straightforward to calculate that for the D4/Dk-brane system it is
\[
\frac{e^\phi}{8 \cdot 4!} F_{ABCD} \left( \Gamma^{ABCD} - \Gamma^M \Gamma^{ABCD} \Gamma_M \right) \Psi = -\frac{3}{4} \frac{\rho}{R^{3/4} r^{5/4}} \Gamma_{S^{k-d-1}\rho\rho\ldots\rho}^{\rho\rho\ldots\rho} \Psi,
\] (8.7)
while by setting \( p = 4 \) in eqs. (4.3) we get
\[
\mathcal{D}_k \Psi_{\ell^\pm} - \frac{\Gamma^M \partial_M \Phi}{2} \Psi_{\ell^\pm} = \left( \frac{R}{r} \right)^{\frac{3}{2}} \Gamma^\rho \partial_\rho \Psi_{\ell^\pm} + \left( \frac{R}{r} \right)^{\frac{3}{2}} \Gamma^\rho \partial_\rho \Psi_{\ell^\pm} \pm \frac{1}{\rho} \left( \frac{r}{R} \right)^{\frac{3}{2}} \left( \ell + \frac{m}{2} \right) \Psi_{\ell^\pm}
\]
\[
+ \frac{1}{R^2} \left( \frac{3 \rho}{8} \frac{m r^2}{2} \right) \Gamma^\rho \Psi_{\ell^\pm}.
\] (8.8)
Substituting eqs. (8.7), (8.8) in (8.2) and imposing the projection $\Gamma^\rho\psi = -\psi$, we are led to the following first-order equation of motion

$$\left\{ \left( \frac{R}{r} \right)^{\frac{3}{2}} \Gamma^\rho \partial_\rho + \left( \frac{r}{R} \right)^{\frac{3}{2}} \Gamma^\rho \partial_\rho + \frac{1}{R^2} \left[ \frac{3}{4} \rho + \left( \ell + \frac{m}{2} \right) \frac{r^2}{\rho^2} + 1 \right] \right. + \frac{1}{4} \left( \ell + \frac{m}{2} \right) \frac{r^2}{\rho^2} \right\} \psi^{\ell \pm} = 0. \tag{8.9}$$

Applying the procedure which was described in section 4 to eq. (8.9), we construct the following second-order differential equation

$$\left( A_1^{\pm} \partial_\rho^2 + A_2^{\pm} \partial_\rho + A_3^{\pm} M^2 + A_4^{\pm} \Gamma^\rho + A_5^{\pm} \right) \psi^{\ell \pm}(\rho) = 0, \tag{8.10}$$

where

$$A_1^{\pm} = 1, \quad A_2^{\pm} = \frac{m}{\rho} + \frac{9}{4} \rho^2 + 1, \quad A_3^{\pm} = \frac{1}{(\rho^2 + 1)^{3/2}},$$

$$A_4^{\pm} = \frac{31 + 2\ell + m}{4} \frac{1}{\rho^2 + 1} \pm \frac{1}{\rho^2} \left( \ell + \frac{m}{2} \right) - \frac{3}{8} \frac{\rho^2}{(\rho^2 + 1)^2},$$

$$A_5^{\pm} = \frac{3}{8} \frac{1}{\rho^2 + 1} (3m - 2m + 1 \mp 4\ell) - \frac{39}{64} \frac{\rho^2}{(\rho^2 + 1)^2} - \frac{1}{\rho^2} \left( \ell^2 + m\ell + \frac{m}{2} \right). \tag{8.11}$$

Employing the projection $\Gamma^\rho \psi^{\ell \pm} = \psi^{\ell \pm}$ and using eqs. (8.10) and (8.11) one can readily obtain the fermionic second-order ordinary differential equation for $\psi^{\ell \pm}(\rho)$. In case of positive spinorial harmonics ($\ell^+$), we get the differential equation of $\psi^{\ell \pm}_{G\ell}(\rho)$, while for negative spinorial harmonics ($\ell^-$), the differential equation of $\psi^{\ell \pm}_{F\ell}(\rho)$ is obtained. The corresponding bosonic equations of motion for the D4/Dk-brane setups ($k = \{4, 6, 8\}$), can be determined from eqs. (C.2)–(C.4) by setting $p = 4$. For all possible D4/Dk-brane systems the transformation

$$\psi^{\ell \pm}_{G\ell}(\rho) = \frac{1}{(1 + \rho^2)^{9/16}} f_{\ell + 1}(\rho), \tag{8.12}$$

maps the fermionic function $\psi^{\ell \pm}_{G\ell}(\rho)$ to the bosonic function $f_{\ell + 1}(\rho)$, while the transformation

$$\psi^{\ell \pm}_{F\ell}(\rho) = \frac{1}{(1 + \rho^2)^{9/16}} f_{\ell}(\rho), \tag{8.13}$$

maps the fermionic function $\psi^{\ell \pm}_{F\ell}(\rho)$ to the bosonic function $f_{\ell}(\rho)$. Notice as well that the above transformations can be obtained from (1.1) by setting $p = 4$.

The above equations of motion cannot be solved analytically (as in the case of bosonic mesons) and we have to resort to numerical analysis. We show explicitly the first few numerical values of the masses in Table 9. The numerical values for $n$ and $\ell$ describe the $F$ operators and one needs to shift appropriately the $\ell$ to read off the value of the $G$ states.

9 Epilogue

In this work we have considered BPS brane intersections in Type IIA/B theories in static equilibrium that include fields in the fundamental representation of the gauge group. We
have studied and derived systematically the equations of motion from the fermionic completion of the DBI action. We have showed the degeneration between the bosonic and fermionic states by providing the necessary transformations to map the equations of motion from the latter to the former ones. We state the transformation rules once more. The map is given by:

$$\psi^{\oplus}_{\ell}(\varrho) = \frac{1}{(1 + \varrho^2)^{n(7-p)}} f_{\ell+1}(\varrho), \quad \psi^{\ominus}_{\ell}(\varrho) = \frac{1}{(1 + \varrho^2)^{n(7-p)}} f_{\ell}(\varrho),$$

where in the above we denote by $\oplus$ superscript the supergravity modes obtained by considering the projection $\Gamma^\rho \Psi^\oplus = \Psi^\oplus$ and we reserve the $\ominus$ for the negative eigenvalue of the projection.

In addition to that, we have checked the supersymmetric degeneracy of the bosonic and fermionic masses numerically in each probe-brane system. We have explicitly computed the value of $\bar{M}^2$ by solving the bosonic as well as the fermionic equations of motion and derived the same masses as expected. We remind at this stage and for the final time, that we have already performed the appropriate shifts in the $\ell$ quantum number as described in [15] in order to keep the presentation of our tables brief. We have included our numerical estimations for the masses in the various sections of the main body of the paper, see Tables 2 to 9. Hence, we have derived the necessary equations to study the dynamics of world-volume fermions in holographic top-down systems and performed crucial checks regarding their validity.

As a by-product of our studies we managed to show that these states obey the field theory mass scaling relation that baryons have in the large-$N_c$ limit when we fix the other

| $\ell$ | $n$ | 0   | 1   | 2   | 3   |
|-------|-----|-----|-----|-----|-----|
| 0    |     | 5.0604 | 14.068 | 27.856 | 46.573 |

**Table 9.** Numerical results of the parameter $\bar{M}^2$ for the D4/D$k$ brane intersections. The top left table pertains to the D4/D8 and the top right one depicts results for the D4/D6 brane intersection. The bottom table is related to the D4/D4 setup.
quantum numbers \((n\) which counts the nodes of the wavefunction and \(\ell\) which is the angular momentum of the fields\)

\[ M^2 \sim N_c^2. \]

We also discussed what we consider to be the precise interpretation of this result. Namely we concluded that this result should be valid if one manages to solve the true dynamic string baryon vertex in the limit where the field theory is at the conformal window (exhibits walking dynamics).

We would like to comment on further new possible directions below: The most straightforward generalisation of our considerations can be performed in the context of eleven-dimensional supergravity. The supersymmetric M-brane junctions are M2/probe-M5, M5/probe-M5 and M2/probe-M2. The bosonic cases have been performed already in [21] where it was found that the equations of motion coincide with the D1/probe-D5, D4/probe-D4 and the F1/probe-D2 systems respectively. In this notation by F1 we denote the fundamental string. We believe that the approach we developed here is directly applicable in these systems.

One of the approaches that has been followed in order to construct gravity duals of more realistic gauge theories with a reduced amount of symmetry is to replace the five-dimensional sphere of the \(AdS_5 \times S^5\) background with a five-dimensional Sasaki-Einstein space. We denote the latter generically by \(\mathcal{M}^5\). Doing so we obtain a duality between string theory in \(AdS_5 \times \mathcal{M}^5\) and a super-conformal quiver theory. By now we know many such models explicitly. The first example that was studied in the literature is the so-called Klebanov-Witten model where we have \(\mathcal{M}^5 = T^{1,1}\) [47]. We also have at our disposal infinite five (and also higher) dimensional spaces of cohomogeneity 1 and 2. These manifolds are called \(Y^{p,q}\) [48] and \(L^{p,q,r}\) [49, 50] respectively, with already existing work on supersymmetric brane embeddings in these backgrounds [51, 52]. It would be an interesting project to derive the corresponding mass spectra of mesonic states in these cases.

It would also be interesting to derive the fermionic spectra of gravity duals that describe chiral symmetry breaking (\(\chi_{SB}\)). The most straightforward example of \(\chi_{SB}\) in the context of holography is provided by the D3/probe-D7 with a non-trivial NS flux (Kalb-Ramond field) on the probe-brane [53]. The main conceptual difference between this system of \(\chi_{SB}\) and the systems that we have considered here, is the non-trivial dependence of the embedding function on the holographic radial coordinate. In the magnetic field example instead of having the separation of the background and the probe branes to be a constant, it is a non-trivial function \(L(\rho)\) that depends on the holographic radial coordinate. Geometrically this means that the probe-brane is curved. The practical issue in cases with such embeddings is the manipulation of the \(\Gamma\)-matrix projections in order to construct an ordinary second-order differential equation to apply the general steps we developed here.

Finally, it would be interesting to understand the dynamics of world-volume fermions in anisotropic RG flows in type IIB supergravity. These RG flows are solutions from the isotropic fixed points to the anisotropic ones. There are solutions in the literature [54] that describe the D3/D7 brane setup which extend from the familiar \(AdS_5\) solution in the UV to the anisotropic solution in the IR. This generalisation of the AdS/CFT duality to
include the description of Lifshitz-like fixed points was initiated in \cite{55} and is interesting in the context of condensed matter theory and applications thereof. We believe that the general approach we developed here is applicable in these systems as well, and might also make computations more feasible.

Acknowledgments

We would like to thank Nick J. Evans and Johanna Erdmenger for collaboration on related topics and discussions, as well as Daniel Aréan and Alfonso V. Ramallo for sharing their private notes at the initial stages of this project. We are thankful to Nick J. Evans and Panagiota Kanti for a crucial read and comments on the final draft of this paper. The research of T.N. was co-financed by Greece and the European Union (European Social Fund-ESF) through the Operational Programme “Human Resources Development, Education and Lifelong Learning” in the context of the project “Strengthening Human Resources Research Potential via Doctorate Research — 2nd Cycle” (MIS-5000432), implemented by the State Scholarships Foundation (IKY). Both authors would like to dedicate this work to the memory of Pavlos Fyssas.

\appendix

\section{Conventions and notation}

We find it necessary to collect and clarify our conventions and notation for the various manipulations of the main body of our work in this appendix. We begin by discussing the different letters that have appeared throughout the various sections.

Capital letters $A,B,C,...$ denote type IIA/B coordinates and they take values in the range $(0,...,9)$. The space described by the $Z$-coordinates corresponds to spatial coordinates which are transverse to the background $Dp$-branes. Its dimensionality is equal to $(9-p)$. Lower-case Greek letters $\mu,\nu,...$ are the Minkowski indices which correspond to the spacetime coordinates of the D$p$-brane. The letters $\rho$ and $\varrho$ denote the radial and the rescaled dimensionless radial coordinate, respectively. Hatted indices $\hat{A},\hat{B},...$ parametrize the spacetime spanned by the probe $Dk$-brane. $Y$-coordinates denote the $(k-d)$-dimensional internal space to the probe brane. Finally, we use the set \{\(w^1,w^2,...,w^{9-p-k+d}\)\} of coordinates to specify the subspace of the original ten-dimensional geometry that is transverse to both the background and the probe branes. Indices enclosed within brackets, i.e \((A),(\mu)\), take values according the aforementioned rules and denote the passing to the vielbein basis.

For the components of a $p$-form we use the convention

\[
X_{(p)} \equiv \frac{1}{p!} X_{\mu_1\mu_2...\mu_p} dx^{\mu_1} \wedge dx^{\mu_2} \wedge ... \wedge dx^{\mu_p} = X_{[\mu_1\mu_2...\mu_p]} | dx^{\mu_1} \wedge dx^{\mu_2} \wedge ... \wedge dx^{\mu_p}. \quad (A.1)
\]

In the above relation, the vertical bars denote that only components with increasing indices are included in the summation.
Definition of the Hodge star operator: let us consider an $n$-dimensional spacetime and the usual $\{dx^M\}$ basis which satisfies the relation $ds^2 = g_{\mu\nu}dx^\mu dx^\nu$, then the dual of the $q$-form (with $q < n$) $dx^{\mu_1} \wedge \ldots \wedge dx^{\mu_q}$ is defined as

$$
\star (dx^{\mu_1} \wedge dx^{\mu_2} \wedge \ldots \wedge dx^{\mu_q}) = \left( \frac{-g^{(n)}}{(n-q)!} \right) g^{\mu_1 \nu_1} g^{\mu_2 \nu_2} \ldots g^{\mu_q \nu_q} \epsilon_{\nu_1 \nu_2 \ldots \nu_q \nu_{q+1} \ldots \nu_n} dx^{\nu_{q+1}} \wedge \ldots \wedge dx^{\nu_n},
$$

(A.2)

where $g^{(n)} = \det(g_{\mu\nu})$, $\epsilon_{012\ldots n} = 1$. The star $\star$ is called Hodge star operator. Using the above equation, we can determine the dual of a $p$-form $X(p)$, namely it is

$$
\star X(p) = \sqrt{-g^{(n)}} \sqrt{\epsilon} g^{\mu_1 \nu_1} g^{\mu_2 \nu_2} \ldots g^{\mu_p \nu_p} \epsilon_{\nu_1 \nu_2 \ldots \nu_p \nu_{p+1} \ldots \nu_n} dx^{\nu_{p+1}} \wedge \ldots \wedge dx^{\nu_n},
$$

(A.3)

with $p < n$.

Let us now consider the vielbein basis $\{e^{(\mu)}\}$, which satisfies the relation $ds^2 = \eta(\mu,\nu)e^{(\mu)}e^{(\nu)}$. In this case, we would have

$$
\star \left( e^{(\mu_1)} \wedge \ldots \wedge e^{(\mu_q)} \right) = \epsilon^{(\mu_1)(\nu_1) \ldots \epsilon^{(\mu_q)(\nu_q)} \epsilon(\nu_1) \ldots (\nu_q) (\nu_{q+1}) \ldots (\nu_n) e^{(\nu_{q+1})} \wedge \ldots \wedge e^{(\nu_n)}.
$$

(A.4)

\section{Vielbeins and spin-connection components of a unit $N$-sphere}

The line-element which defines the geometry of a unit $N$-sphere is of the following form

$$
ds^2 = d\Omega_N^2 = d\theta_1^2 + \sum_{i=2}^{N} \prod_{j=1}^{i-1} \sin^2 \theta_j d\theta_i^2.
$$

(B.1)

It is straightforward to deduce that the vielbeins for the geometry above are given by

$$
e^{(\bar{m})}_1 = \delta_{\bar{m}}^1, \quad e^{(\bar{m})}_n = \prod_{j=1}^{n-1} \sin \theta_j \delta_{\bar{m}}^n, \quad 1 < n \leq N,
$$

(B.2)

while the spin-connection components can be expressed in a compact form as

$$
\omega^{(\bar{m})}_{(\bar{n})} = \sum_{k=2}^{N} \delta_{k}^{i_1} \sum_{j=1}^{k-1} \delta_{\bar{m}}^j \delta_{\bar{n}}^j \cot \theta_j \prod_{\ell=j}^{k-1} \sin \theta_{\ell} - \sum_{k=2}^{N} \delta_{k}^{i_1} \delta_{\bar{m}}^n \delta_{\bar{n}}^k \cos \theta_{k-1}
$$

$$
- \sum_{k=3}^{N} \delta_{k}^{i_1} \sum_{j=1}^{k-2} \delta_{\bar{m}}^j \delta_{\bar{n}}^j \cos \theta_j \prod_{\ell=j+1}^{k-1} \sin \theta_{\ell}.
$$

(B.3)

In the above expressions we kept the same bar notation to be consistent with section 2.3.
C Scalar mesons, probe branes and numerical spectra

There has been extensive work in the literature studying the bosonic spectra and states of probe-brane setups. Here we will limit ourselves to a minimal discussion and quoting the basic relations. This we do for convenience with our numerical approach. Original and detailed work on this can be found in [20, 21].

Firstly, it is more useful to re-organize the probe brane junction in the following way: we have $D^p/D^{p+4}$, $D^p/D^{p+2}$, and $D^p/D^p$ systems. In the first class of probe-brane embeddings, $p$ is allowed to have values $0 \leq p \leq 4$. For co-dimension one defect $p$ can be $1 \leq p \leq 4$. Finally, for $D^p/D^p$ systems we have $2 \leq p \leq 4$.

In all of the above systems, when considering an appropriate shift in the $\ell$ quantum number, the dynamics of the bosonic degrees of freedom can be mapped to those of scalar orthogonal fluctuations from the DBI action of the form

$$Y^A = \delta_0^A L + 2\pi\alpha'\varphi^A$$

with $A$ ranging from 5, $\cdots$, $9-p$, 4, $\cdots$, 9-p and 3, $\cdots$, 9-p for the $D^p/D^p+4$, $D^p/D^p+2$, and $D^p/D^p$ systems respectively. Therefore, the most basic equations of motion that needs to be solve in the one pertaining to the above modes and we have:

$$\partial_\varrho^2 f_\ell(\varrho) + \frac{3}{\varrho} \partial_\varrho f_\ell(\varrho) + \left( \frac{\bar{M}^2}{(1 + \varrho^2)^{(7-p)/2}} - \frac{\ell(\ell+2)}{\varrho^2} \right) f_\ell(\varrho) = 0, \quad \text{for the } D^p/D^p+4,$$

$$\partial_\varrho^2 f_\ell(\varrho) + \frac{2}{\varrho} \partial_\varrho f_\ell(\varrho) + \left( \frac{\bar{M}^2}{(1 + \varrho^2)^{(7-p)/2}} - \frac{\ell(\ell+1)}{\varrho^2} \right) f_\ell(\varrho) = 0, \quad \text{for the } D^p/D^p+2,$$

$$\partial_\varrho^2 f_\ell(\varrho) + \frac{1}{\varrho} \partial_\varrho f_\ell(\varrho) + \left( \frac{\bar{M}^2}{(1 + \varrho^2)^{(7-p)/2}} - \frac{\ell^2}{\varrho^2} \right) f_\ell(\varrho) = 0, \quad \text{for the } D^p/D^p,$$

where in the above we have considered an appropriate decomposition of the $\varphi^A$ and thus $f$ is a scalar function of the radial coordinate. The final equation does not have normalizable solutions for zero angular momentum excitation and therefore the states with $\ell = 0$ are considered non-physical.

In [20, 21] the authors have given explicitly tables for some cases. For direct comparison, convenience and completeness, here we generate the numerical results and present them in tables that are complementary to those ones.

Our numerical approach for the bosonic spectra is the following:

- We are shooting from the $\Lambda_{\text{IR}}$ to the $\Lambda_{\text{UV}}$ by fine-tuning $\bar{M}^2$ such that the mode solutions are normalizable in the UV and small in amplitude [15].
- We choose as initial conditions $f(\varrho)|_{\varrho \to 0} = \varrho^\ell$ and $\partial_\varrho f(\varrho)|_{\varrho \to 0} = \ell \varrho^{\ell-1}$ [20, 21].
- We use $\Lambda_{\text{IR}} = 10^{-7}$ and $\Lambda_{\text{UV}} = 10$.
