1. Introduction

Limited fossil fuels and global warming are increasingly threatening human survival and have been serious global issues for decades. New power plants using fuel sources such as solid oxide fuel cells (SOFCs) have attracted much attention around the world, and the technology is expected to reduce obstacles in the supply of electricity in the future. The advantage of SOFCs compared with other types of fuel cells is that they are a more efficient and flexible fuel source. The main obstacle to solid oxide fuel cells (SOFCs) implementation is the high operating temperature in the range of 800–1,000 °C so that it has an impact on high costs. SOFCs work at high temperatures causing rapid breakdown between layers (anode, electrolyte, and cathode) because they have different thermal expansion. The study focused on reducing the operating temperature in the medium temperature range. $\text{SmBa}_{0.5}\text{Sr}_{0.5}\text{Co}_2\text{O}_{5+\delta}$ (SBSC) oxide was studied as a cathode material for IT-SOFCs based on $\text{Ce}_{0.8}\text{Sm}_{0.2}\text{O}_{1.9}$ (SDC) electrolyte. The SBSC powder was prepared using the solid-state reaction method with repeated ball-milling and calcining. Alumina grinding balls are used because they have a high hardness to crush and smooth the powder of SOFC material. The specimens were then tested as cathode material for SOFC at intermediate temperature (600–800 °C) using X-ray powder diffraction (XRD), thermogravimetric analysis (TGA), electrochemical, and scanning electron microscopy (SEM) tests. The X-ray powder diffraction (XRD) pattern of SBSC powder can be indexed to a tetragonal space group (P4/mmm). The overall change in mass of the SBSC powder is 8% at a temperature range of 125–800 °C. A sample of SBSC powder showed a high oxygen content (5+δ) that reached 5.92 and 5.41 at temperatures of 200 °C and 800 °C, respectively. High diffusion levels and increased surface activity of oxygen reduction reactions (ORR) can be affected by high oxygen content (5+δ). The polarization resistance (Rp) of samples sintered at 1000 °C is 4.02 $\Omega$cm$^2$ at 600 °C, 1.04 $\Omega$cm$^2$ at 700 °C, and 0.42 $\Omega$cm$^2$ at 800 °C. The power density of the SBSC cathode is 336.4, 387.3, and 357.4 W/cm$^2$ at temperatures of 625 °C, 650 °C, and 675 °C, respectively. The SBSC demonstrates as a prospective cathode material for IT-SOFC.

SOFCs also offer low pollutant emissions because the final stage of their usage only produces vapor or hot water [1–3]. The schematic diagram exhibiting the basic operation of SOFC is shown in Fig. 1, a. At the cathode side, the oxygen reduction reaction occurs by accepting electrons from the external circuit. The reactions can be written below:

$$O_2 + 4e^- \rightarrow 2O^2-$$  \hspace{1cm} (1)

The produced oxide ions ($O^{2-}$) pass through the electrolyte to the anode side and combine with the protons produced by the oxidation of hydrogen or other fuels to produce water. The reactions can be written as follows:

$$2H_2 + 2O^{2-} \rightarrow 2H_2O + 4e^-$$  \hspace{1cm} (2)

Overall reaction,

$$2H_2 + O_2 \rightarrow 2H_2O$$  \hspace{1cm} (3)

This reaction occurs at the three-phase boundary (TPB) [4]. The TPB is the interfacial area among electrode, electrolyte, and gaseous fuel where the overall reaction occurs (Fig. 1, b). The electrons flowing from the anode to the cathode produce electrical work in the "Load".

![Schematic diagram: a - SOFC operation; b - three-phase boundary (TPB)](image)

Through the process, chemical energy is directly converted to electrical energy. To increase the active area where the oxygen reduction reaction (cathode) or hydrogen oxidation reaction (anode) occurs, a porous electrode structure is employed. Meanwhile, the dense electrolyte provides a physical barrier to prevent the direct mixing of fuel and air.

### 2. Literature review and problem statement

In general, traditional SOFCs operate at high temperatures, which causes several problems including high production costs, mismatches in thermal expansion between the fuel cell components, and chemical compatibility. Therefore, current research is focused on SOFCs that can operate at lower temperatures (400–800°C) and aims to reduce production costs and achieve a long working lifetime (40,000 h) [5–7]. Lower operating temperatures cause the catalytic activity of the electrodes to decrease significantly, and the cathode is a limiting factor for the overall fuel cell performance. Therefore, the focus is being directed toward maintaining stability in the cathode material and increasing the high electrochemical performance of IT-SOFCs. In other words, a vital result of the research into fuel cell performance is the discovery that the cathode polarization can be eliminated [8]. However, the application of SOFC is widely constrained due to the impact of low catalytic activity on the oxygen reduction reactions (ORRs) at the cathode. Mixed ionic-electronic conductor cathodes (MIECs) are successful in increasing the active ORR zone from the three-phase boundary to the cathode-gas interface site, which will reduce cathodic resistance [8, 9]. The ORR site of MIECs works on the TPB (the electrolytes, cathodes, and gas phases) and at the two-phase boundary between the gas phase and the cathode [10].

Recently, among the various MIECs oxides, cobalt-containing perovskite oxides such as Sm-Ba$_{0.8}$Sr$_{0.2}$Co$_2$O$_{4-δ}$ [11], PrBa$_{0.5}$Sr$_{0.5}$Co$_2$Fe$_2$O$_{4-δ}$ [12], NdBa$_{0.5}$Sr$_{0.5}$Co$_2$O$_{4-δ}$ [13], YBa$_{0.5}$Sr$_{0.5}$Co$_2$O$_{4-δ}$ [14], and GdBa$_{0.5}$Sr$_{0.5}$Co$_2$Fe$_2$O$_{4-δ}$ [15] have attracted strong interest due to their electrocatalytic activity performance for the ORR. Also, the investigation has been conducted for layered perovskites with the chemical formula LnBa$_{2-x}$Co$_x$O$_{4-δ}$ (Ln-selected lanthanides) [16–23]. Several research groups also have investigated the electrochemical properties of a new type of MIEC oxide, cation ordered Ln-BaCo$_2$O$_{4+δ}$ (Ln=La, Pr, Sm, Gd, Y), as a potential cathode material for IT-SOFCs. Cobalt in cathodes is beneficial for the activation of oxygen reduction and thus provides a lower activation polarization loss. Cobalt-based cathodes, however, have high thermal expansion coefficients (TECs) because of the low-spin to the high-spin transition of Co. The incompatibility in thermal expansion can cause thermal stress in SOFCs and thus result in poor long-term thermal stability [13]. Therefore, it is important to improve the thermal expansion compatibility between the cathodes and the electrolytes. Zhou et al. [24] have declared that LnBa$_2$Co$_x$O$_{4+δ}$ cathodes with an intermediate lanthanide-ion radius, such as Sm$^{3+}$, may provide a compromise between the values of the catalytic activity and thermal expansion coefficients. Recent reports exhibit when A' site is partially substituted by Sr, it could potentially improve the conductivity of double perovskite oxides where Sr-doped oxide YBa$_{0.5}$Sr$_{0.5}$Co$_2$O$_{4-δ}$ demonstrated excellent conductivity values (about 32 times higher than that of the Sr-free sample). Moreover, the Sr-doped layered perovskite oxide system LnBa$_{2-x}$Sr$_x$Co$_2$O$_{4+δ}$ (Ln=Pr, Sm, and Gd), which showed a lower polarization resistance based on doped ceria electrolyte [25]. However, observations of SOFC performance in the range of 625, 650, and 675 °C.
have not been experimentally investigated. From the research reported above, some of the obstacles that SOFC faced were high working temperatures and high thermal expansion differences in SOFC components. Efforts were made to overcome this problem, the use of SBSC material as a cathode is expected to reduce the working temperature of SOFC so that the compatibility of SOFC components meets the requirements. In this work, SBSC oxide is synthesized, and aspects of its structural characteristics, thermal and electrochemical performance, power density, and microstructure are investigated. The SBSC oxygen reduction mechanism is also observed under various oxygen partial pressures (OPPs).

3. The aim and objectives of the study

The aim of this study was to analyze the performance of double perovskite oxides used in intermediate-temperature solid oxide fuel cells.

To achieve this aim, the following objectives are accomplished:
- to modify the structure of SBSC cathode by the solid-state reaction technique;
- to investigate the polarization resistance ($R_p$) of SBSC cathode and the maximum power density obtained in the single SOFC;
- to test the performance of SBSC cathodes at intermediate operating temperatures.

4. Materials and methods for preparing and testing specimens

Fig. 2 shows the procedure of preparation for the single cell specimen, which consists of three SOFC elements, namely anode, electrolyte and cathode materials. The synthesis methods for the cathodes and electrolytes are described in previously published papers [11, 26]. The SBSC cathode powder was prepared using a solid-state reaction technique. The stoichiometric amounts of cathode material (Sm$_2$O$_3$, BaCO$_3$, SrCO$_3$, and CoO) were ball-milled in ethanol for 12 h. The slurry was then heated at a temperature of 1,000 °C in the air for 6 h. The Ce$_{0.8}$Sm$_{0.2}$O$_3$ (SDC) powder was synthesized using the coprecipitation technique using the precursor materials Ce(NO$_3$)$_3$.6H$_2$O and Sm(NO$_3$)$_3$.6H$_2$O. A stoichiometric ratio was applied, distilled water was then used to dissolve the starting material before being added to the ammonia solution.

The pH value ranging from 9.5 to 10 is applied to the mixed solution. The precipitate was washed three times after it was filtered using distilled water and ethanol. In the next process, the co-precipitation powder was heated at 600 °C and held in the air for 2 h. For a binding agent, a small amount of polyvinyl alcohol (PVA) with a purity grade of 96% was mixed into the SDC powder and then pelletized to dimensions of 1.5 cm in diameter and 0.1 cm in thickness using uniaxial pressure applied at 1,000 kg f/cm$^2$. The disk-shaped sample was heated at 1,500 °C and held for 5 h, followed by cooling to room temperature [26]. The procedure stages of fabricating a single cell specimen are presented in Fig. 2. The structure of the SBSC cathode powder was observed by XRD using Rigaku D/MAX-2500V, the radiation source of Cu K$\alpha$ (1.5418 Å), and a scanning range of 10°–80°. To explain the lattice parameter and powder pattern for the sample, we used the GSAS program to perform a Rietveld refinement. The SBSC cathode microstructure (top view) and the cross-sectional image of the symmetrical cell were investigated by SEM (Hitachi 3400N). The TG/DTA 6300 was used to analyze the thermo-gravimetric behavior of SBSC cathodes in the air (100 cm$^3$/min). The oxygen content was calculated using the following formula:

$$δ = \frac{M \Delta m}{M_m}$$

(4)

5. Results of SBSC Performance Test

5.1. Crystal Structure

The crystal structure and phase composition of the SBSC powder were observed using X-ray diffraction (XRD). From the GSAS software analysis, characteristic XRD peaks were
detected as double perovskite oxide. The peaks caused by impurities are not detected in the structure of SBSC, which indicates a well-prepared sample. Meanwhile, the lattice parameters are obtained: $a = 3.861$ Å, $b = 3.861$ Å, $c = 7.617$ Å, and $\alpha = 113.56$ Å$^2$, with reliability factors of $R_\text{wp} = 0.41$ and $R_p = 0.23$. In this structure, Sm atoms are in position 1a, Sr, and Ba atoms are randomly distributed at position 1b. The cell parameters regarding the SBSC cathode structure collected from Rietveld refinement are described in Table 1.

### Table 1

| Atom | Wyckoff position | $x$ | $y$ | $z$ | Uiso | Occ |
|------|------------------|-----|-----|-----|------|-----|
| Sm   | 1a (0 0 0)       | 0   | 0   | 0   | 0.0333 | 0.8797 |
| Co   | 2h (½ ½ z)      | 1/2 | 1/2 | 0.25592 | 0.0045 | 0.9944 |
| Ba/Sr| 1b (0 0 ½)      | 0   | 0   | 1/2 | 0.0092 | 0.8926 |
| O1   | 4i (0 ½ z)       | 0   | ½   | 0.26780 | 0.0077 | 0.9311 |
| O2   | 1c (½ ½ 0)      | 1/2 | 1/2 | 0   | 0.1906 | 1.2455 |
| O3   | 2h (½ ½ z)      | 1/2 | 1/2 | 0.44110 | 0.0333 | 0.4220 |

Meanwhile, the Co atom occupies position 2h (0.5, 0.5, z). The SBSC structure has three kinds of oxygen atom sites: O3 at 2h (0.5, 0.5, z), O2 at 1c (0.5, 0.5, 0), and O1 at 4i (0, 0.5, z).

Fig. 3 shows the refinement of SBSC patterns, including the measured XRD data, the calculated profile, and the difference between them. The refinement using the General Structure Analysis System (GSAS) program is typically used for crystallographic analysis, quantitative phase determination, texture mapping, stress-strain measurements, and other related types of materials characterization. The test results agree with the measured profiles, indicating that in the perovskite lattice, cations are well ordered.

![Fig. 3. Rietveld refinement data of the SBSC cathode at room temperature](image)

The space group, fractional coordinates, and lattice parameters of corresponding double perovskite structure cathodes are shown in Table 2.

| Specimens         | Space group | a(Å) | b(Å) | c(Å) | V(Å³) | Rp   |
|-------------------|-------------|------|------|------|-------|------|
| NdBaCoO$_5$       | P4/mmm      | 3.903| 3.903| 7.614| 116.02| 0.42 |
| SmBaCoO$_5$       | P4/mmm      | 3.886| 7.833| 7.560| 230.22| 0.45 |
| NdBa$_{0.5}$Sr$_{0.5}$CoO$_5$ | P4/mmm | 3.861| 3.861| 7.715| 115.01| 0.36 |
| SmBa$_{0.5}$Sr$_{0.5}$CoO$_5$ | P4/mmm | 3.855| 3.855| 7.705| 114.54| 0.12 |
| SmBa$_{0.66}$Sr$_{0.34}$CoO$_5$ | P4/mmm | 3.870| 3.870| 7.590| 114.11| 0.29 |
| SmBa$_{0.66}$Sr$_{0.34}$CoO$_5$ | P4/mmm | 3.883| 3.883| 7.580| 114.30| 0.28 |

The SBSC cathode showed high structural stability when the samples were calcined under temperatures of 1,000 °C and 1,200 °C, which does not influence the crystal structure [33].

### 5.2. Thermal properties and oxygen content analysis

To clarify the oxygen content of the SBSC cathode, TGA was conducted in the air. The TGA curve indicates that the specimen had a slight weight loss before 125 °C, which is associated with the desorption of the specimen's absorbed water as presented in Fig. 4, a. With a further increase in temperature, the magnitude of weight loss became significant and continued until weight loss slowed at temperatures of 250–325 °C.

![Fig. 4. Curve data: a – TGA of the SBSC powder over a temperature range between 27 °C and 800 °C; b – oxygen content (5+δ) as a function of temperature in air for SBSC cathodes](image)
Above 325 °C, the rate of degradation in weight loss was significant, and the mass change slowed again at temperatures around 725 °C. It can be seen that from 650 °C to 750 °C the weight loss rate tends to increase. Then, at a temperature range of 750 °C, weight loss seems to slow down again until it reaches a temperature of 800 °C. Detailed oxygen content (5+δ) information as a function of temperature is listed in Table 3.

| Specimens       | Calcination temperature (°C) | 200 °C | 400 °C | 600 °C | 800 °C |
|-----------------|------------------------------|--------|--------|--------|--------|
| SBSC91 [25]     | 1,200                        | 5.53   | 5.44   | 5.32   | 5.18   |
| SBSC73 [25]     | 1,200                        | 5.62   | 5.55   | 5.36   | 5.22   |
| SBSC55 [25]     | 1,200                        | 5.74   | 5.64   | 5.51   | 5.39   |
| SBSC [this work]| 1,000                        | 5.92   | 5.76   | 5.60   | 5.41   |

The calcination temperature has an impact on the oxygen content of the SBSC cathode. The oxygen content of the cathode with a calcination temperature of 1,200 °C is smaller than that of a calcined one at a temperature of 1,000 °C. In the cathode with the calcination temperature of 1,200 °C, the oxygen content values were 5.74 (200 °C) and 5.39 (800 °C), while in the cathode with the calcination temperature of 1,000 °C, the oxygen content values obtained were 5.92 and 5.41.

5.3. OPP Half-Cell

Typical impedance spectra for symmetrical cells (SBSC|SDC|SBSC) were obtained by AC impedance spectroscopy. Fig. 5 shows the fitting data of impedance spectra for symmetrical cells measured at different temperatures such as a – 600 °C; b – 700 °C; and c – 800 °C, serially. While the various OPPs were employed from 0.214–0.035 atm. The polarization resistance \( R_p \) was a function of \( p(O_2) \), which is investigated under various temperatures between 600 °C to 800 °C with the OPPs ranged from 0.214 to 0.035 atm.

The \( R_p \) values increased with decreasing \( p(O_2) \) values due to the decrease in mobile interstitial oxygen at lower \( p(O_2) \) values. The fitting of the impedance spectrum for symmetrical cells using the Z-View program.

The \( R_p \) value of the specimen was significantly reduced at 800 °C with an oxygen partial pressure (OPP) of 0.214 atm as presented in Fig. 6.

| \( p(O_2) \) (atm) | \( R_p \) (Ω cm²) |
|-------------------|-----------------|
|                   | 600 °C | 700 °C | 800 °C |
| 0.214             | 4.02   | 1.04   | 0.42   |
| 0.112             | 4.02   | 1.06   | 0.43   |
| 0.074             | 4.90   | 1.08   | 0.45   |
| 0.050             | 5.10   | 1.10   | 0.47   |
| 0.035             | 5.32   | 1.20   | 0.49   |

The cathode cell performance is influenced by the \( R_p \) values obtained from the components. The high \( R_p \) values have a significant impact on SOFC performance. In general, the value of \( R_p \) has decreased with the increase in the working temperature of the SOFC. In these conditions, the manufacture of SOFC components, especially the high density between layers (anode, electrolyte, and cathode), is of great concern to researchers.
5.4. Single-Cell Performance

Fig. 7 shows the single-cell performance of anode-supported Ni-SDC|SDC|SBSC under air/humidified hydrogen (3 vol% H₂O). Increasing temperature has an impact on increasing the current density and power density due to the thermally activated kinetic process [34]. Due to the same phenomenon, cell voltage increased at higher temperatures. Fig. 4 also indicates that the open-circuit voltages (OCVs) are 0.83, 0.81, and 0.84 at 425 °C, 450 °C, and 475 °C, respectively; these values are lower than the theoretical values.

In Fig. 8, the adhesion between the SDC electrolyte and the SBSC cathode layer is quite good. Fig. 8, b consists of two layers covering the SCBC (cathode) on the top and SDC (anode) on the bottom. The white line shows the two-layer boundary between the cathode and anode. The SBSC cathode grain size is distributed uniformly in the range of 1.5–2 μm and is porous.

5.5. SEM Image

Fig. 8 displays the SEM images of a – cross-sectional image of the SBSC cathode in the SBSC|SDC|SBSC symmetrical-cell specimen and b – top view of the SBSC cathode. In the symmetric cell, the cathode layer of SBSC was calcined in air for 2 h at 1,000 °C. A uniform porous microstructure facilitates the gas diffusion of the cathode layer. A well-connected electrolyte–cathode interface determines low resistance in the solid oxide fuel cell.

6. Discussion of experimental results

The XRD pattern of SBSC powder, which can be categorized into a tetragonal space group (P4/mmm) is as shown in Fig. 3, after calcining at 1,000 °C for 6 h. There is a good compatibility level between the experimental data and calculated profiles, which shows that the cations are ordered well in the perovskite lattice arrangement between the Sm³⁺ and Ba²⁺/Sr²⁺ ions [35].

The overall change in mass of the SBSC powder reached 8% at temperatures of 125–800 °C. Previous data showed that the specimen was beginning to lose lattice oxygen significantly at a specific temperature [36]. Lattice oxygen is concerned with the reduction and oxidation of perovskite
oxides. The oxygen void is experienced by perovskite oxide when lattice oxygen is released. A partial loss of lattice oxygen, along with a reduction in Co\(^{3+}\) to Co\(^{2+}\), or Co\(^{4+}\) to Co\(^{3+}\), and an increase in temperature, causes a decrease in weight loss during heating. Therefore, the oxygen content decreases with temperature [37, 38]. The high diffusivity regarding oxide ions and the increased surface activity of the ORRs might be due to a high oxygen content [39].

To clarify the polarization of the SBSC cathode resistance, the symmetrical cells test was carried out with various OPPs from 0.214–0.035 atm. From the data, with increasing temperatures, the \(R_p\) values fell dramatically, suggesting that the SBSC sample ORR is a thermally activated process. The \(R_p\) values of the specimen reduced from 4.02 \(\Omega\) cm\(^2\) at 600 °C to 0.42 \(\Omega\) cm\(^2\) at 800 °C with an OPP of 0.214 atm as presented in Fig. 6. However, the \(R_p\) values increased significantly with a decreasing oxygen partial pressure. For instance, as \(p(\text{O}_2)\) decreases from 0.214 to 0.035 atm, the \(R_p\) value increases from 4.02 to 5.32 \(\Omega\) cm\(^2\) at a temperature of 600 °C. This study is consistent with the results previously reported by Meng et al. regarding changes in polarization resistance to oxygen partial pressure [40]. The \(R_p\) values reflect cathodic behavior, including diffusion of oxygen at high temperatures in the gas phase, low-temperature ORR, and the surface of bulk diffusion/oxygen [41].

From single cell testing, ideally, the OCV of a cell should be similar to its 1.1 V theoretical value and should be small only if affected by factors of operating conditions. Porosity impacts the leakage current when fuel/oxidants crossing the electrolyte membrane can cause low OCV values. The following equation can explain the concept of chemical defect:

\[
\text{Ce}_{1+x} \rightarrow \text{Ce}^+ + h.
\]  

(5)

Electrolyte-based materials with low electronic conductivity, such as SDC, may lead to a slight electron cross flow via the electrolyte. Alternatively, Ce\(^{4+}\) in SDC electrolytes is quickly reduced to Ce\(^{3+}\), particularly at higher temperatures [29]. The power density values of the cell with an SBSC cathode are 336.1, 387.3, and 357.4 mW/cm\(^2\) at 625 °C, 650 °C, and 675 °C, respectively. One method of improving cell performance is by modifying the cathode surface using electrolyte-based materials such as SDC. As previously reported, SDC nanoparticles implanted into the porous surface of the cathode produce a significant increase in the power density value [42].

Fig. 8 shows a cross-sectional view of SBSC|SDC from the prepared symmetrical cell and top surface SEM images. The SBSC cathode grain size is distributed uniformly in the range of 1.5–2 μm and is porous. Better morphology is very helpful to ensure increased current, reduced \(R_p\) values, and rapid oxygen diffusion during SOFC operations. Also, the cathode structure's properties determine the cell performance in processes such as kinetic reactions, mass transportation preprocessing, and charge transportation [43].

Overall, we have presented the SBSC perovskite oxide investigation in this report. However, a more comprehensive study is needed to improve SOFC performance, including thermal expansion testing to determine the degradation resistance between SOFC layers. In the future work, we will focus on increasing the value of open-circuit voltage (OCV) using a dense bi-layer electrolyte of Yttria-stabilized Zirconia (YSZ)/Samaria doped Ceria (SDC) through pulsed laser deposition (PLD) technique. YSZ dense layer prepared by pulsed laser deposition (PLD) technique as a blocking layer improved the stability of the SDC electrolyte and inhibited electronic current leakage. This method is expected to increase the value of OCV and the single-cell performance.

7. Conclusions

1. The XRD structure of the SBSC cathode has been successfully categorized as double perovskite oxide by the solid-state reaction method. The double perovskite structure consists of the elements Sm\(^{3+}\), Ba\(^{2+}\) on the A side and Sr\(^{2+}\), Co\(^{3+}\), Co\(^{4+}\) on the B side.

2. The \(R_p\) values of the specimen decreased from 4.02 \(\Omega\) cm\(^2\) at 600 °C to 0.42 \(\Omega\) cm\(^2\) at 800 °C. The maximum power density of the single cell is 387.3 mW/cm\(^2\) at 650 °C, indicating that SBSC is qualified as the SOFC cathode material.

3. SBSC cathodes show good performance at intermediate operating temperatures (600–800 °C).
