Abstract

The noncommutative selfdual $\phi^3$ model in 6 dimensions is quantized and essentially solved, by mapping it to the Kontsevich model. The model is shown to be renormalizable and asymptotically free, and solvable genus by genus. It requires both wavefunction and coupling constant renormalization. The exact ("all-order") renormalization of the bare parameters is determined explicitly, which turns out to depend on the genus 0 sector only. The running coupling constant is also computed exactly, which decreases more rapidly than predicted by the one-loop beta function. A phase transition to an unstable phase is found.

1 Introduction

This paper is the third part of a series of papers [1, 2] studying the quantization of a noncommutative "self-dual" $\phi^3$ model, by mapping it to the Kontsevich model. The model is characterized by an additional potential term in the action, which takes care of the UV/IR mixing following [3–6]. In the previous papers we discussed the cases of 2 and 4 dimensions, and showed that the model is renormalizable and essentially solvable. These cases are in some sense simpler because they are super-renormalizable. This is no longer the case in 6 dimensions, where new renormalization is required at each order, and the full complexity of an interacting quantum field theory is found with both wavefunction and coupling constant renormalization.

$^1$Work supported by the FWF project P18657.
Indeed, the commutative $\phi^3$ model in 6 dimensions is known [7] to be asymptotically free.

Generalizing [1, 2], we show in this paper that the selfdual NC $\phi^3$ model in 6 dimensions can be renormalized and essentially solved in terms of a genus expansion. This is possible again using the results of [8, 9] on the Kontsevich model, which most however be properly renormalized. The model has 6 relevant parameters. In particular, both coupling constant and wavefunction renormalization are required in the 6-dimensional case, in addition to tadpole and mass renormalization which were sufficient in 2 and 4 dimensions. Remarkably, we find again that the renormalization is determined by the genus 0 sector only, as in the case of 2 and 4 dimensions.

After renormalization, all $n$-point functions can be computed in principle in terms of a genus expansion, and we give explicit expressions for the 1-, 2-, and some 3-point functions. We also find a critical surface $\alpha = 0$ in moduli space, which separates 2 different phases. This provides a model which contains the full complexity of renormalization of a non-super-renormalizable asymptotically free quantum field theory, while being solvable and hence fully under control. It is very remarkable that a 6-dimensional interacting NC field theory allows such a detailed analytical description. It can therefore also serve as a testing ground for various approximation methods, which is of interest also in a more general context.

In particular, we are able to determine exactly the RG flow of the bare parameters, as well as the running of the “physical” coupling constant i.e. the 1PI 3-point function. We find that the 1-loop beta function for the coupling constant correctly predicts asymptotic freedom, but wrongly predicts a $(\log N)^{-1/2}$ dependence on the scale as opposed to the correct $(\log N)^{-2}$ dependence.

Beyond the selfdual case $\Omega = 1$, perturbative renormalizability of similar models has been established using variants of a renormalization group approach, see e.g. [3–5, 10–12]. The present approach using matrix model methods is certainly appropriate for the case $\Omega = 1$. We indicate in section 5 how it might be extended to $\Omega \neq 1$, which however is not carried out here. For a related matrix approach to NC field theory see also [13, 14].

Being a continuation of our previous work on the 2- and 4-dimensional case, we will be brief in certain issues which have already been discussed there, and which apply without change. Nevertheless, the present paper is essentially self-contained. In section 2 we define the $\phi^3$ model under consideration, and rewrite it as Kontsevich model. We then briefly recall the most important facts about the Kontsevich model in section 3. The main technical analysis is contained in section 4.1, while the main results of this paper are collected in section 4.2. The asymptotic behavior of the 1-, 2- and 3-point functions is determined in section 4.3, and further aspects such as relation with string field theory are briefly discussed in section 5. The perturbative results such as the one-loop beta-function are given in section 6, and we conclude with a general discussion and outlook.
2 The noncommutative selfdual $\phi^3$ model

We consider the noncommutative $\phi^3$ model on the 6-dimensional quantum plane $\mathbb{R}_\theta^6$, which is generated by self-adjoint operators $x_i$ satisfying the canonical commutation relations

$$[x_i, x_j] = i\theta_{ij},$$

for $i, j = 1, \ldots, 6$. We also introduce

$$\tilde{x}_i = \theta^{-1}_{ij} x_j, \quad [\tilde{x}_i, \tilde{x}_j] = i\theta^{-1}_{ji}$$

assuming that $\theta_{ij}$ is nondegenerate. The model to be studied is defined by the action

$$\tilde{S} = \int_{\mathbb{R}_\theta^6} \left( \frac{1}{2} \partial_i \phi \partial_i \phi + \frac{\mu^2}{2} \phi^2 + \Omega^2 (\tilde{x}_i \phi)(\tilde{x}_i \phi) + \frac{i\lambda_0}{3!} \phi^3 \right).$$

An additional oscillator-type potential $\Omega^2 (\tilde{x}_i \phi)(\tilde{x}_i \phi)$ is included following [3–6], making the model covariant under Langmann-Szabo duality, and taking care of the UV/IR mixing. The dynamical object is the scalar field $\phi = \phi^\dagger$, which is a self-adjoint operator acting on the representation space $\mathcal{H}$ of the algebra (1). The action is written with imaginary coupling $i\lambda_0$, so that the quantization is well-defined for real $\lambda_0$; otherwise the action would be unbounded. We will see however that after quantization, one can perform an analytic continuation to real $\lambda'_0 = i\lambda_0$.

Noting that the $\partial_i$ are inner derivatives $\partial_i f = -i[\tilde{x}_i, f]$, the action can be written as

$$\tilde{S} = \int \left( \frac{1}{2} \partial_i \phi \partial_i \phi + \frac{\mu^2}{2} \phi^2 + \Omega^2 (\tilde{x}_i \phi)(\tilde{x}_i \phi) + \frac{i\lambda_0}{3!} \phi^3 \right).$$

In order to quantize the theory, we need to include a linear (tadpole) counterterm $-Tr(i\lambda)A\phi$ to the action (the explicit factor $i\lambda$ is inserted for convenience). Replacing the integral by $\int \rightarrow (2\pi\theta)^3 Tr$ and adding a constant term for convenience, we are led to consider the action

$$S = Tr \left( \frac{1}{2} J \phi^2 + \frac{i\lambda}{3!} \phi^3 - (i\lambda)A\phi - \frac{1}{3(i\lambda)^2} J^3 - JA \right).$$

Here $J = 2Z(2\pi\theta)^3(\sum_i \tilde{x}_i \tilde{x}_i + \frac{\mu^2}{2})$ is essentially the Hamiltonian of a 3-dimensional quantum mechanical harmonic oscillator. A wavefunction renormalization $Z$ has

\textsuperscript{2}We ignore operator-technical subtleties, since the model will be regularized using a cutoff $N$.\hfill\textsuperscript{3}
also been introduced, which for the cubic term is absorbed in the redefined coupling constant \( \lambda \), in order to simplify the notation. The field \( \phi \) will be the renormalized, finite physical field. In the usual basis of eigenstates, \( J \) then diagonalizes as

\[
J|n_1, n_2, n_3\rangle = 16\pi^3 \theta^2 Z (n_1 + n_2 + n_3 + \frac{\mu^2 \theta + 3}{2})|n_1, n_2, n_3\rangle, \quad n_i \in \{0, 1, 2, ...\}
\]

assuming that \( \theta_{ij} \) has the canonical form \( \theta_{12} = -\theta_{21} = \theta_{34} = -\theta_{43} = ... =: \theta \). To simplify the notation, we will use the convention

\[
n \equiv (n_1, n_2, n_3), \quad n \equiv n_1 + n_2 + n_3
\]

throughout this paper, keeping in mind that \( n \) denotes a triple-index. It turns out that we need

\[
A = a_0 + a_1 J + a_2 J^2.
\]

By suitable shifts\(^3\) in the field \( \phi \)

\[
\tilde{\phi} = \phi + \frac{1}{i\lambda} J = X + \frac{1}{i\lambda} M
\]

one can now either eliminate the linear term or the quadratic term in the action,

\[
S = Tr\left(-\frac{1}{2i\lambda} M^2 \tilde{\phi} + \frac{i\lambda}{3!} \tilde{\phi}^3\right) = Tr\left(\frac{1}{2} M X^2 + \frac{i\lambda}{3!} X^3 - \frac{1}{3(i\lambda)^2} M^3\right)
\]

where

\[
M = \sqrt{J^2 + 2(i\lambda)^2 A} = xZ \sqrt{J^2 + d}
\]

\[
\tilde{J} = \frac{J}{Z} + \frac{(i\lambda)^2 a_1}{x^2 Z},
\]

\[
x = \sqrt{1 + 2(i\lambda)^2 a_2},
\]

\[
d = -\left(\frac{(i\lambda)^2 a_1}{x^2 Z}\right)^2 + 2 \frac{(i\lambda)^2 a_0}{x^2 Z^2}.
\]

(11) has precisely the form of the Kontsevich model [9]. The linear coupling of the field to the source \( M^2 \) resp. \( \tilde{J}^2 \) will be very useful for computing correlation functions. \( \tilde{J} \) now has eigenvalues

\[
\tilde{J}|n_1, n_2, n_3\rangle = 16\pi^3 \theta^2 (n_1 + n_2 + n_3 + \frac{\mu^2 \theta + 3}{2})|n_1, n_2, n_3\rangle
\]

which will be finite after renormalization, and

\[
\delta \mu^2 \theta = \mu^2 \theta - \mu^2_R \theta = -\frac{16 \pi^3 \theta^2}{16 \pi^3 \theta^2} \frac{(i\lambda)^2 a_1}{x^2 Z}.
\]
2.1 Quantization, partition function and correlators

The quantization of the model (6) resp. (11) is defined by an integral over all Hermitian $N^3 \times N^3$ matrices $\phi$, where $N$ serves as a UV and IR cutoff. The partition function

$$Z(M) = \int D\tilde{\phi} \exp \left( -Tr\left( -\frac{1}{2i\lambda} M^2 \tilde{\phi} + \frac{i\lambda}{3!} \tilde{\phi}^3 \right) \right) = e^{F(M)}$$

(18)

defines the “free energy” $F(M)$, which is a function of the eigenvalues of $M$ resp. $\tilde{J}$. Since $N$ is finite, we can freely switch between the various parametrizations (6), (11) involving $M$, $J$, $\phi$, or $\tilde{\phi}$. Correlators or “$n$-point functions” are defined through

$$\langle \phi_{i_1j_1}...\phi_{i_nj_n} \rangle = \frac{1}{Z(M)} \int D\phi \exp(-S) \phi_{i_1j_1}...\phi_{i_nj_n},$$

(19)

keeping in mind that each index denotes a multi-index (8). Using the symmetry $Z(M) = Z(U^{-1}MU)$ for $U \in U(N^3)$, we can assume that $M$ is diagonalized with ordered eigenvalues $m_i$. There is a residual $U(1) \times U(3) \times U(6) \times ...$ symmetry, reflecting the degeneracy of $J$. This implies certain obvious “index conservation laws”, such as $\langle \phi_{kl} \rangle = \delta_{kl} \langle \phi_{ll} \rangle$ etc.

The nontrivial task is to show that all these $n$-point functions with finite indices have a well-defined and nontrivial limit $N \to \infty$, for a suitable scaling of the bare parameters. In addition, the index dependence of these $n$-point functions must be nontrivial. Recall that the wavefunction renormalization is already taken into account in (7), so that $\phi$ is the finite, physical field. The free parameters should in principle be determined by choosing renormalization conditions, such as $\langle \phi_{00}\phi_{00} \rangle = \frac{1}{2\pi \mu^2 \theta + 1}$, etc. These conditions can easily be solved using the explicit results given in sections 4.1 and 4.2, relating the bare parameters with the “physical” quantities.

Noting that the field $\tilde{\phi}$ couples linearly to $M^2$ resp. $\tilde{J}^2$ in (18), one can compute the connected $n$-point functions by acting with the derivative operator $2i\lambda \frac{\partial}{\partial J^2} = 2i \frac{\lambda}{x^2 Z} \frac{\partial}{\partial \tilde{J}^2}$ on $F$. Anticipating some results below, we introduce the quantities

$$i\lambda_R = \frac{i\lambda}{x^2 Z^2}, \quad r = \frac{1}{x^2 Z}$$

(20)

which turn out to be finite after renormalization. Then

$$\langle \tilde{\phi}_{i_1j_1}...\tilde{\phi}_{i_nj_n} \rangle_c = (2i\lambda_R \frac{\partial}{\partial \tilde{J}^2_{i_1j_1}})...(2i\lambda_R \frac{\partial}{\partial \tilde{J}^2_{i_nj_n}}) F(\tilde{J}^2).$$

(21)

Since the connected $n$-point functions are independent of the shifts $\tilde{\phi} = \phi + \frac{f}{x^2}$ (10) for $n \geq 2$, the rhs coincides with the desired correlator $\langle \phi_{i_1j_1}...\phi_{i_nj_n} \rangle_c$ for $n \geq 2$. This strongly suggests that $\lambda_R$ should be finite.
Using the Dyson-Schwinger equations for the path integral (18), one can derive a number of nontrivial identities for the $n$-point functions. Since their derivation was already given in [1], we simply quote them here with the appropriate substitutions. In particular, one finds for the propagator

$$\langle \tilde{\phi}_{kl}(\tilde{\phi}_{lk}) \rangle = \frac{2i\lambda}{m_k^2 - m_l^2} \langle \tilde{\phi}_{kk} - \tilde{\phi}_{ll} \rangle$$  \hspace{1cm} (22)$$

for $k \neq l$ (no sum), where $m_k$ denotes the eigenvalues of $M$. This gives

$$\langle \phi_{kl}(\phi_{lk}) \rangle = \frac{2r}{J_k + J_l} + \frac{2i\lambda R}{J_k^2 - J_l^2} \langle \phi_{kk} - \phi_{ll} \rangle$$  \hspace{1cm} (23)$$

using (12). The first term has the form of the free contribution, and the second is a quantum correction. The latter reduces to the 1-point functions, which will be obtained from the Kontsevich model. Similarly, one can show [1]

$$\langle \tilde{\phi}_{kl}(\tilde{\phi}_{lk} \tilde{\phi}_{kk}) \rangle = \frac{2i\lambda}{m_k^2 - m_l^2} \langle (\tilde{\phi}_{kk} - \tilde{\phi}_{ll}) \tilde{\phi}_{kk} - \tilde{\phi}_{kl} \tilde{\phi}_{lk} \rangle$$  \hspace{1cm} (24)$$

(no sum) for $k \neq l$. Using (23), this gives the connected part

$$\langle \phi_{kl}(\phi_{lk} \phi_{kk}) \rangle_c = \frac{2i\lambda}{m_k^2 - m_l^2} \left( \langle (\phi_{kk} - \phi_{ll}) \phi_{kk} \rangle_c - \langle \phi_{kl}(\phi_{lk}) \rangle \right).$$  \hspace{1cm} (25)$$

Clearly these relations can be generalized, greatly reducing the number of independent correlators. However, we will establish finiteness of the general correlation functions directly, by showing that the appropriate derivatives of the generating function $F(\tilde{J})$ are finite and well-defined after renormalization.

### 3 The Kontsevich model: facts and background

The Kontsevich model is defined as a matrix integral

$$Z_{Kont}(\tilde{M}) = e^{\mathcal{F}_{Kont}} = \frac{\int dX \exp \left\{ Tr \left( -\frac{\tilde{M}X^2}{2} + i\frac{X^3}{6} \right) \right\}}{\int dX \exp \left\{ -Tr \left( \frac{\tilde{M}X^2}{2} \right) \right\}}$$  \hspace{1cm} (26)$$

over hermitian $N^3 \times N^3$ matrices $X$, where the parameter $\tilde{M}$ is some given hermitian $N^3 \times N^3$ matrix. This model has been introduced by Kontsevich [9] as a combinatorial way of computing certain topological quantities (intersection numbers) on moduli spaces of Riemann surfaces with punctures. It turns out to have an extremely rich structure related to integrable models (KdV flows) and Virasoro
constraints. For our purpose, the most important results are those of [8,9,15] which provide explicit expressions for the genus expansion of the free energy. Note that $\lambda$ can be introduced by rescaling the variables, writing $M = \lambda^{2/3} \hat{M}$.

The matrix integral in (26) and its large $N$ limit can be defined rigorously in terms of its asymptotic series. This involves the variables [9]

$$ t_r := -(2r + 1)! \theta_{2r+1}, \quad \theta_r := \frac{1}{r} \text{Tr} \hat{M}^{-r}. \quad (27) $$

Then the large $N$ limit of the partition function $Z_{\text{Kont}}(\hat{M})$ can be rigorously defined [8,9], which turns out to be a function of these new variables only, $Z_{\text{Kont}}(\hat{M}) = Z_{\text{Kont}}(\theta_r)$. In our case, $\theta_r$ is divergent for $r = 1, 2, 3$, which indicates that the model requires renormalization.

One can furthermore consider the genus expansion

$$ \ln Z_{\text{Kont}} = F_{\text{Kont}} = \sum_{g \geq 0} F_g^{\text{Kont}} \quad (28) $$

by drawing the Feynman diagrams on the appropriate Riemann surface, as usual for matrix models. In [8] it was shown that all $F_g^{\text{Kont}}$ can be computed using the KdV equations and the Virasoro constraints, which allows to find closed expressions for any genus $g$. They are given in terms of the following variables

$$ I_k(u_0, t_i) = \sum_{p \geq 0} t_{k+p} \frac{u_0^p}{p!} = -(2k - 1)! \sum_i \frac{1}{(\tilde{m}_i^2 - 2u_0)^{k+1/2}}, \quad (29) $$

where $u_0$ is given by the solution of the implicit equation

$$ u_0 = I_0(u_0, t_i) = -\sum_i \frac{1}{\sqrt{\tilde{m}_i^2 - 2u_0}} \quad (30) $$

These variables turn out to be more useful for our purpose. Using the KdV equations, [8] obtain the following explicit formulas:

$$ F_0^{\text{Kont}} = \frac{1}{3} \sum_i \tilde{m}_i^3 - \frac{1}{3} \sum_i (\tilde{m}_i^2 - 2u_0)^{3/2} - u_0 \sum_i (\tilde{m}_i^2 - 2u_0)^{1/2} $$

$$ + \frac{u_0^3}{6} - \frac{1}{2} \sum_{i,k} \ln \left\{ \frac{(\tilde{m}_i^2 - 2u_0)^{1/2} + (\tilde{m}_k^2 - 2u_0)^{1/2}}{\tilde{m}_i + \tilde{m}_k} \right\} \quad (31) $$

$$ F_1^{\text{Kont}} = \frac{1}{24} \ln \frac{1}{1 - I_1}; \quad (32) $$

$$ F_2^{\text{Kont}} = \frac{1}{5760} \left[ 5 \frac{I_4}{(1 - I_1)^3} + 29 \frac{I_3 I_2}{(1 - I_1)^4} + 28 \frac{I_2^3}{(1 - I_1)^5} \right], \quad (33) $$
etc. This form of $F_0$ was first found in [15]. The sums over multi-indices (8) are to be interpreted as

$$\sum_i \equiv \sum_{i_1, i_2, i_3 = 0}^{N-1}$$

truncating the harmonic oscillators in (7). For our purpose, the most important result is that all $F_{Kont}^g$ with $g \geq 2$ are given by polynomials $F_{Kont}^g = \sum \chi\{l_k\} x_1^{l_2} \cdots x_{3g-2}^{l_{3g-2}}$ in $x_k = I_k/(1 - I_1)^{2k+1}$ with the constraint

$$\sum_{2 \leq k \leq 3g-2} (k-1)l_k = 3g - 3,$$

(34)

where $l_k$ is the power of $x_k$, and $\chi\{l_k\}$ is some (rational) intersection number.

While many of these expressions are divergent as $N \to \infty$ for $\tilde{J}$ given by (16), the physically relevant observables will be convergent after renormalization.

### 4 The Kontsevich model applied to the $\phi^3$ model

In order to apply the above results to the noncommutative $\phi^3$ model, we need the following slightly modified version of the Kontsevich model, corresponding to the action (11):

$$Z(M) = \exp(F(M)) = Z^{Kont}[\tilde{M}] Z^{free}[\tilde{M}] \exp\left(\frac{1}{3(i\lambda)^2} Tr M^3\right)$$

(35)

where

$$F_0 := F_{0}^{Kont} + F_{free} + \frac{1}{3(i\lambda)^2} Tr M^3$$

$$= -\frac{1}{3} \sum_i \sqrt{\tilde{m}_i^2 - 2u_0^3} - u_0 \sum_i \sqrt{\tilde{m}_i^2 - 2u_0^3}$$

$$+ \frac{u_0^3}{6} - \frac{1}{2} \sum_{i,k} \ln(\sqrt{\tilde{m}_i^2 - 2u_0} + \sqrt{\tilde{m}_k^2 - 2u_0})$$

(36)

and $F_g = F_{g}^{Kont}$ for $g \geq 1$. In the present case, the eigenvalues $\tilde{m}_i$ are given by (12)

$$\tilde{m}_i = \lambda^{-2/3} x Z \sqrt{\tilde{J}^2_i + d}.$$  

(37)

The model as it stands is ill-defined for $N \to \infty$, since $u_0$ and many of the above sums are divergent. However, we can recast (36) using more appropriate variables, which suggests how to renormalize the various parameters, i.e. how to scale them.
with $N$. Note that only the combinations $\sqrt{\tilde{m}^2_i - 2u_0}$ enter in (29) and (36), which can be rewritten using (12) as

$$\sqrt{\tilde{m}^2_i - 2u_0} = xZ\lambda^{-2/3}\sqrt{\tilde{J}^2_i + 2b}.$$  \hspace{1cm} (38)

Here $b$ is defined through

$$\frac{x^3Z^3}{(i\lambda)^2} \left( b - \frac{1}{2}d \right) = xZ\lambda^{-2/3}u_0 = -\sum_i \frac{1}{\sqrt{\tilde{J}^2_i + 2b}}$$  \hspace{1cm} (39)

using the constraint (30), which is replaced by (39) henceforth. Eliminating $u_0$ using (39) and expressing $\lambda$ in terms of $\lambda_R$, $F_0$ takes the form

$$F_0 = \frac{1}{3(i\lambda_R)^2xZ} \sum_i \sqrt{\tilde{J}^2_i + 2b} - \frac{b - \frac{1}{2}d}{(i\lambda_R)^2xZ} \sum_i \sqrt{\tilde{J}^2_i + 2b}$$

$$- \frac{(b - \frac{1}{2}d)^3}{6(i\lambda_R)^4x^2Z^2} - \frac{1}{2} \sum_{i,k} \ln \left( \frac{1}{(\lambda_R^2xZ)^{1/3}} \right) \left( \sqrt{\tilde{J}^2_i + 2b} + \sqrt{\tilde{J}^2_k + 2b} \right).$$ \hspace{1cm} (40)

The quantities $\tilde{J}$, $b$ and $\lambda_R$ will be finite after renormalization, rendering the model well-defined. We consider $F = F(\tilde{J}^2)$ as a function of (the eigenvalues of) $\tilde{J}^2$ from now on, while $b$ is implicitly determined by (39). Since the eigenvalues $\tilde{J}_k$ only enter through the combination $\sqrt{\tilde{J}^2_k + 2b}$, we note that the eigenvalues can be analytically continued as long as this square-root is well-defined.

We can now compute various $n$-point functions by taking partial derivatives of $F = \sum_g F_g$ with respect to $\tilde{J}^2$, as indicated in section 2.1. For the “diagonal” $n$-point functions $\langle \tilde{\phi} \tilde{\phi} \rangle_c$, this amounts to varying the eigenvalues $\tilde{J}^2_k$. In doing so, we must remember that $b$ depends implicitly on $\tilde{J}^2_k$ through the constraint (39). However, some of these computations simplify recalling that the constraint (39) for $b$ arises automatically through the e.o.m: using

$$\frac{\partial}{\partial b} F_0(\tilde{J}^2_i; b) = -\frac{1}{2} \left( \frac{b - \frac{1}{2}d}{(i\lambda_R)^2xZ} + \sum_i \frac{1}{\sqrt{\tilde{J}^2_i + 2b}} \right)^2 = 0$$ \hspace{1cm} (41)

we can write

$$\frac{d}{d\tilde{J}^2_i} F_0(\tilde{J}^2_i) = \frac{\partial}{\partial \tilde{J}^2_i} F_0(\tilde{J}^2_i; b) + \frac{\partial}{\partial b} F_0(\tilde{J}^2_i; b) \frac{\partial}{\partial \tilde{J}^2_i} b = \frac{\partial}{\partial \tilde{J}^2_i} F_0(\tilde{J}^2_i; b).$$ \hspace{1cm} (42)

Thus for derivatives of order $\leq 2$ w.r.t. $\tilde{J}^2_k$, we can simply ignore $b$ and treat it as independent variable, since the omitted terms (41) vanish anyway once the constraint is imposed.
4.1 Renormalization

This section contains some computations required to show finiteness of the \( n \)-point functions for any genus \( g \). This will establish Theorem 1 in section 4.2.

The 1-point function

We can now determine the required renormalization by considering the one-point function. Using (40), (41) and (39), the genus zero contribution is

\[
\langle \phi_{kk} \rangle_{g=0} = 2i\lambda_R \frac{\partial}{\partial J_k^2} F_0(\tilde{J}^2) - \frac{J_k}{i\lambda_R x^2 Z^2} F_0(\tilde{J}^2)
\]

\[
= \frac{1}{i\lambda_R x^2 Z} y_k + (i\lambda_R) \sum_j \frac{1}{y_k \sqrt{J_j^2 + 2b + (\tilde{J}_j^2 + 2b)}} - \frac{r}{i\lambda_R} \tilde{J}_k + i\lambda_R Z^2 a_1
\]

\[=: W(y_k) \tag{43} \]

using (20), which must be finite and well-defined as \( N \to \infty \). Here we define

\[y_k = \sqrt{\tilde{J}_k^2 + 2b}. \tag{44} \]

We will find that \( W(y) \) becomes a smooth function of \( y \) after renormalization, which amounts to the statement that the index dependence of the one-point function is “smooth”. This is a typical feature of matrix models, reflecting some “smooth” distribution of eigenvalues. This becomes here part of the statement of renormalizability. To proceed, we need to understand the function

\[f(y) := \sum_j \frac{1}{y \sqrt{J_j^2 + 2b + (\tilde{J}_j^2 + 2b)}} \tag{45}\]

which as it stands is ill-defined for \( N \to \infty \).

4.1.1 Renormalization of \( f(y) \)

In order to make sense of \( f(y) \), we consider the Taylor-expansion of

\[f(y; \tilde{J}) = \sum_j \frac{1}{y \sqrt{J_j^2 + 2b + (\tilde{J}_j^2 + 2b)}} = f_0(\tilde{J}) + y f_1(\tilde{J}) + f_R(y; \tilde{J}) \tag{46}\]

in \( y \), in analogy to the usual strategy in renormalization. Here

\[f_0(\tilde{J}) = \sum_j \frac{1}{\tilde{J}_j^2 + 2b} = f_0 + f_{0,R}(\delta \tilde{J}) \tag{47}\]
\[ f_1(\tilde{J}) = - \sum_j \frac{1}{(\tilde{J}_j^2 + 2b)^{3/2}} = f_1 + f_{1,R}(\delta \tilde{J}) \] (48)

\[ f_R(y; \tilde{J}) = y^2 \sum_j \frac{1}{(\tilde{J}_j^2 + 2b)(y\sqrt{\tilde{J}_j^2 + 2b} + (\tilde{J}_j^2 + 2b))}. \] (49)

where \( f_1, f_2 \) are divergent constants obtained by fixing \( \tilde{J} \) as in (16), while the \( f_{i,R}(\delta \tilde{J}) \) are regular (convergent) functions obtained by taking into account variations \( \delta \tilde{J} \) of the eigenvalues. This is necessary e.g. to compute partial derivatives w.r.t. \( \tilde{J} \). Thus

\[ f_0 = \frac{1}{(16\pi^3\theta^2)^3} \int_0^N dx_1dx_2dx_3 \frac{1}{(x_1 + x_2 + x_3 + \frac{3 + \mu_R^2\theta}{2})} + \text{finite} \]
\[ = \frac{1}{(16\pi^3\theta^2)^3} \left( (6 \log(2) - 3 \log(3))N - \frac{3 + \mu_R^2\theta}{2} \log(N) \right) + \text{finite} \] (50)

and similarly

\[ f_1 = - \frac{1}{2} \frac{1}{(16\pi^3\theta^2)^3} \log(N) + \text{finite}. \] (51)

The remaining part \( f_R(y; \tilde{J}) \) is well-defined and convergent, provided \( b \) and \( \tilde{J}_k \) i.e. \( \mu_R \) are finite, which will be assumed from now on\(^4\). To understand it better, we note that

\[ f''_R(y) = f''(y) = 2 \sum_j \frac{\tilde{J}_j^2 + 2b}{(y\sqrt{\tilde{J}_j^2 + 2b} + (\tilde{J}_j^2 + 2b))^3} \]

is positive, and similarly \( f''_R(y) \geq 0 \). Hence \( f_R(y) \) is a rather simple convex smooth function of \( y > 0 \), which satisfies \( f_R(0) = f''_R(0) = 0 \), and it remains only to determine its asymptotic behavior for large \( y \approx \tilde{J}_N \), i.e. small \( x \). This can be obtained by writing

\[ f_R(y) \approx \frac{y}{(16\pi^3\theta^2)^3} \int_{\tilde{J}_0/y}^{\tilde{J}_N/y} dx \frac{1}{(x^2 + 2b/y^2)^2} (x^2 + 2b/y^2 + (x^2 + 2b/y^2)) \] (52)

where \( x = \frac{\tilde{J}}{y} \). This integral is convergent for large \( x \), but logarithmically divergent at the origin i.e. for large \( y \sim J_N \). We can hence replace the upper integration limit in (52) by \( x = 1 \), to obtain the asymptotic behavior for large \( y \):

\[ f_R(y) \approx \frac{y}{(16\pi^3\theta^2)^3} \int_{\tilde{J}_0/y}^{1} dx \frac{1}{(x^2 + 2b/y^2)^{3/2}} \approx \frac{1}{2} \frac{1}{(16\pi^3\theta^2)^3} y \log(\frac{y}{J_0}). \] (53)

\(^4\)We do not pursue the possibility of divergent \( \mu_R \), which does not appear to be interesting.
4.1.2 Renormalization of \( \langle \phi_{kk} \rangle_{g=0} \)

We have seen that only \( f_0 \) and \( f_1 \) are divergent in (46), while \( f_R(y_k) \) is finite and well-defined as \( N \to \infty \). Then (43) becomes

\[
\langle \phi_{kk} \rangle_{g=0} = \frac{y_k}{i\lambda_R x Z} - \frac{r\tilde{J}_k}{(i\lambda_R)} + i\lambda_R Z^2 a_1 + i\lambda_R(f_0(\tilde{J}) + y_k f_1(\tilde{J}) + f_R(y_k; \tilde{J}))
\]

\[
= (i\lambda_R Z^2 a_1 + i\lambda_R f_0) + \left( \frac{1}{i\lambda_R x Z} + i\lambda_R f_1 \right) y_k - \frac{r\tilde{J}_k}{i\lambda_R}
\]

\[
+ i\lambda_R \left( f_R(y_k; \tilde{J}) + f_{0,R}(\delta \tilde{J}) + y_k f_{1,R}(\delta \tilde{J}) \right)
\]

\[
= c - \frac{y_k}{i\lambda_R \alpha} - \frac{r\tilde{J}_k}{i\lambda_R} + i\lambda_R \left( f_R(y_k) + f_{0,R}(\delta \tilde{J}) + y_k f_{1,R}(\delta \tilde{J}) \right)
\]

(54)

Here we define the quantities

\[
\alpha = -\frac{x Z}{1 + (i\lambda_R)^2 x Z f_1} = -\frac{1}{x Z + (i\lambda_R)^2 f_1}, \quad (55)
\]

\[
c = i\lambda_R (Z^2 a_1 + f_0). \quad (56)
\]

Since \( \tilde{J}_k \), \( y_k \) and \( f_R(y_k) \) are independent functions of \( k \) (as long as \( b \neq 0 \)), it follows that \( \langle \phi_{kk} \rangle_{g=0} \) is finite if and only if the four quantities

\[
(i\lambda_R, c, \frac{1}{i\lambda_R\alpha}, \frac{r}{i\lambda_R}) \quad (57)
\]

are finite. Remarkably, the condition that \( \alpha \) be finite will also guarantee that the higher genus contributions are finite. The second form of (55) implies that this is possible only for real coupling \( (i\lambda_R) \), since \( x \) and \( Z \) should be positive, while \( f_1 \sim -\log N \).

4.1.3 Higher derivatives and higher genus contributions

The connected part of the \( n \)-point functions for diagonal entries \( \langle \tilde{\phi}_{i_1i_1}...\tilde{\phi}_{i_ni_n} \rangle_c \) are obtained by taking higher derivatives \( (i\lambda_R)^n \frac{\partial}{\partial J_{i_1}}...\frac{\partial}{\partial J_{i_n}} \) of \( F(J^2) \) resp. (54). Since the (infinite) shift \( \tilde{\phi} = \phi + \frac{J}{i\lambda} \) drops out from the connected \( n \)-point function for \( n \geq 2 \), these coincide with \( \langle \phi_{i_1i_1}...\phi_{i_ni_n} \rangle_c \) for \( n \geq 2 \), and we have to show that they are finite.

Consider first the genus 0 contributions. To compute higher derivatives of \( F_0 \) w.r.t. \( J^2 \), we must also take into account the implicit dependence of \( b \) on \( \tilde{J}^2 \). Indeed \( b \) is a smooth function of \( \tilde{J} \) as shown in (66). Furthermore, recall that \( \frac{\partial}{\partial b} F_0(\tilde{J}^2; b) \)
vanishes through the constraint (41), however this is no longer true for the higher
derivatives. In particular, taking derivatives of (41) we find
\[- \frac{\partial^2}{\partial b^2} F_0(\tilde{J}^2_i; b) = \frac{\partial}{\partial b} \left( \frac{b - \frac{1}{2} d}{(i\lambda R)^2 x Z} + \sum_i \frac{1}{\sqrt{\tilde{J}^2_i + 2b}} \right) = \frac{1 - I_1}{(i\lambda R)^2 x Z}, \]
\[- \frac{\partial^2}{\partial \tilde{J}^2_k \partial b} F_0(\tilde{J}^2_i; b) = \frac{\partial}{\partial \tilde{J}^2_k} \left( \frac{b - \frac{1}{2} d}{(i\lambda R)^2 x Z} + \sum_i \frac{1}{\sqrt{\tilde{J}^2_i + 2b}} \right) = \frac{1}{\sqrt{\tilde{J}^2 + 2b}} \] (58)
which are both finite and smooth using (62) below. Combining this with the explicit
form (54) and using the results of section 4.1.1, it follows that all higher derivatives
of $F_0(\tilde{J}^2)$ w.r.t. $\tilde{J}^2$ are finite.

For the higher genus contributions, we also need the derivatives of the quantities
\[ I_k(\tilde{J}^2_i, b) = -(2k - 1)!!(\lambda R x Z)^{2k+1} \sum_i \frac{1}{(\tilde{J}^2_i + 2b)^{k+\frac{1}{2}}} \] (59)
In particular,
\[ I_1(\tilde{J}^2_k, b) = -\lambda^2 R x Z \sum_i \frac{1}{(\tilde{J}^2_i + 2b)^{\frac{1}{2}}} = \lambda^2 R x Z f_1(\tilde{J}) \]
\[ = \lambda^2 R x Z (f_1 + f_{1,R}(\delta \tilde{J})) \] (60)
where $f_{1,R}(\delta \tilde{J})$ is a finite and smooth function (48) of $\tilde{J}^2_k$ and $b$ (which vanishes for
$\delta \tilde{J} = 0$). Hence for $I_1$ to be finite we need
\[ \frac{1}{\lambda^2 R x Z} \sim f_1 \sim \log(N), \] (61)
which using (59) implies that all higher $I_k$ vanish for $N \to \infty$ unless $(1 - I_1) \sim 0$.
Hence the higher-genus contributions can be nontrivial only if we carefully take a
“double-scaling” limit$^5$ and require \[ \frac{I_k}{(1 - I_1)^{2k+1}} \] to be finite, while $I_1 \to 1$. Using (60),
we have
\[ \frac{1}{\lambda^2 R x Z} \frac{1}{(1 - I_1)} = \frac{1}{\alpha(i\lambda R)^2} - f_{1,R}(\delta \tilde{J}) \] (62)
where $\alpha$ is defined in (55). It follows that
\[ \frac{I_k}{(1 - I_1)^{2k+1}} = -\frac{(2k - 1)!!}{(i\lambda R)^2 - f_{1,R}(\delta \tilde{J})} \sum_i \frac{1}{(\tilde{J}^2_i + 2b)^{k+\frac{1}{2}}} \]
\[ \sim -(2k - 1)!!(i\lambda R)^2 \alpha \sum_i \frac{1}{(\tilde{J}^2_i + 2b)^{k+\frac{1}{2}}} \] (63)
$^5$This is quite reminiscent of the double-scaling limit of matrix models in the context of 2D gravity
(the last form holds for $\delta \tilde{J} = 0$) is finite and nontrivial for $k \geq 2$, provided

$$\alpha = \text{finite},$$

assuming that $i\lambda_R$ is finite. In particular, all derivatives of $F_g$ for $g \geq 2$ w.r.t. $\tilde{J}_k^2$ are manifestly finite, and thus all genus $g \geq 2$ contributions to the diagonal $n$-point functions are finite. Using (62) and (32), this also holds for genus 1.

Finally, from the constraint (39) we derive

$$\frac{\partial}{\partial \tilde{J}_k^2} b = -(i\lambda_R)^2 xZ \frac{\partial}{\partial \tilde{J}_k^2} \left( \sum_i \frac{1}{\sqrt{\tilde{J}_i^2 + 2b}} \right)$$

$$= \frac{1}{2} (i\lambda_R)^2 xZ \left( \frac{1}{\sqrt{\tilde{J}_k^2 + 2b}} + \sum_i \frac{2}{\sqrt{\tilde{J}_i^2 + 2b}} \frac{\partial}{\partial \tilde{J}_k^2} b \right)$$

(65)

which using (62) gives

$$\frac{\partial}{\partial \tilde{J}_k^2} b = -\frac{1}{2} \frac{1}{\sqrt{\tilde{J}_k^2 + 2b}} \frac{1}{(i\lambda_R)^2 \alpha} - f_1, R(\delta \tilde{J}).$$

(66)

This is again finite, using the above assumptions. Hence $b$ depends smoothly on the variations in $\tilde{J}_k$ provided $\alpha$ is finite. If $\alpha = \infty$, then the constraint (39) cannot be solved any more for $b$ as a function of the eigenvalues $\tilde{J}$ (and their variation), rendering the model non-renormalizable. This implies that the genus 0 sector fully determines the required renormalization, as was found previously in 2 and 4 dimensions [1, 2].

### 4.2 Main result and renormalization group flow

We have now established all required formulas for the derivatives of $F(\tilde{J})$, and hence for the diagonal $n$-point functions. We also showed that all of these are finite and have a well-defined as $N \to \infty$, provided a few renormalization conditions hold. Let us collect these conditions and use them to determine the required scaling of the bare parameters.

Assume first that $\lambda_R = 0$. Imposing this exactly (i.e. independent of $N$) implies $\alpha = -xZ$ and $i\lambda = i\lambda_R \alpha^2 = 0$. This is the free case with $x$ and $Z$ finite\(^6\), as can be seen e.g. from (54) and (83).

Hence assume $\lambda_R \neq 0$. We assume also that $b \neq 0$ (we will see that this restriction is in fact not important), so that the 4 quantities in (57) are finite. By taking products, this implies that $r$ and $\frac{1}{\alpha}$ are also finite, hence $\alpha \neq 0$. Finite $\alpha$ is in fact

---

\(^6\)We shall not pursue here the possibility of other more subtle scaling limits.
also required for the higher-genus contributions to be finite. Using (55), we then obtain
\[ \frac{1}{xZ} = -(i\lambda_R)^2 f_1 - \frac{1}{\alpha} = \frac{1}{2} \frac{(i\lambda_R)^2}{(16\pi^3\theta^2)^3} \log(N) - \frac{1}{\alpha} \] (67)
which implies\(^7\)
\[ i\lambda = i\lambda_R x^2 Z^2 = \left( -\frac{1}{\alpha} + \frac{1}{2} \frac{(i\lambda_R)^2 \log(N)}{(16\pi^3\theta^2)^3} \right)^2 \sim (i\lambda_R)^{-3} \log(N)^{-2} \] (68)
for large \(N\). Note that in a perturbative approach i.e. if this is formally expanded in terms of \(\lambda_R\), this is divergent and requires renormalization at each order. Nevertheless the closed form (68) is rather simple, with leading behavior \((i\lambda_R)^{-3} \log(N)^{-2}\).

\(Z\) is then determined through
\[ Z = r \frac{i\lambda}{i\lambda_R} \sim \log(N)^{-2} \] (69)
since \(r = \frac{1}{xZ}\) is finite, and similarly
\[ x = \frac{1}{\sqrt{rZ}} \sim \log(N). \] (70)
This gives \(a_2\) using (14). \(a_1\) is determined from (56),
\[ Z^2 a_1 = \frac{c}{i\lambda_R} - f_0 \] (71)
whose leading term is linearly divergent in \(N\), and gives the mass renormalization
\[ \delta \mu^2 \theta = -\frac{2}{16\pi^3\theta^2} \frac{1}{r} Z^2 a_1 \approx \frac{2}{16\pi^3\theta^2} \frac{f_0}{r} \] (72)
using (17) up to finite corrections. Its leading dependence on \(N\) is given by (50). Finally, \(d\) is determined by the constraint (39),
\[ d = 2b + 2(i\lambda_R)^2 xZ \sum_i \frac{1}{\sqrt{j_i^2 + 2b}} \] (73)
which involves the further finite parameter \(b\). Then \(a_0\) follows from (15), which is quadratically divergent in \(N\) in agreement with the perturbative result (121).

Finally, (54) shows that \(\alpha = 0\) marks some singularity or phase transition, dividing the moduli space into two disconnected components with \(\alpha \gtrless 0\). The explicit
\(^7\)note also that (67) implies that \((i\lambda_R)\) should be real, since \(xZ\) should be positive.
form of the 2-point function (83) below shows that the phase with $\alpha < 0$ is the “physically relevant” one, while $\langle \phi_{ij} \phi_{ji} \rangle < 0$ for $\alpha > 0$ for small indices $i, j$. Since the matrices are supposed to be Hermitian, this signals an instability or condensation for the low modes, i.e. some kind of tachyonic behavior. Observe also that e.g. $\langle \phi_{00} \rangle = 0$ can only be realized for $\alpha < 0$. Nevertheless, the renormalized $n$-point functions remain well-defined for $\alpha > 0$. This phase transition is only seen in the genus 0 sector.

Finally consider the case $b = 0$, so that $y_k \equiv \tilde{J}_k$. Then finiteness of the one-point function requires only that the three quantities

$$\left( \frac{i\lambda_R}{\lambda_R}, \frac{1}{i\lambda_R}, \frac{r}{i\lambda_R} \right)$$

(74)

are finite. However, the genus zero result for the 2-point function (83) shows that $\frac{1}{\alpha}$ must also be finite, and we are back to the previous analysis with finite $\alpha \neq 0$.

Putting these results together and recalling the structure of the higher genus contributions $F_g$ stated below (33), we have established the following:

**Theorem 1** All derivatives of $F_g$ w.r.t. $\tilde{J}_k^2$ for $g \geq 0$ (as well as all functions $F_g$ for $g \geq 2$) are finite and have a well-defined limit $N \to \infty$, provided the 6 quantities $(i\lambda_R, \alpha, \mu_R^2, r, c, b)$ are finite and fixed, and $\alpha \neq 0$.

This determines the scaling of the 6 bare parameters

$$(i\lambda(N), Z(N), \mu^2(N), a_0(N), a_1(N), a_2(N))$$

(75)

as a function of $N$ through (68), (69), (72), (73) resp. (15), (71), and (70). This defines a renormalization group flow in the space of free parameters. If desired, we could now impose some specific renormalization conditions such as $\langle \phi_{00} \rangle = 0$ etc.

These would then determine the renormalized parameters $i\lambda_R$ etc., which in turn would determine the bare ones.

The most interesting “real” sector is given by $i\lambda_R \in \mathbb{R}, \alpha < 0, r > 0, \mu_R^2 > -3$ and $b \in \mathbb{R}$ such that $\tilde{J}_k^2 + 2b > 0$ for all $k$. Then $i\lambda \in \mathbb{R}$ for large enough $N$, and $Z$ and $x$ are positive. The case $\alpha = 0$ is a singularity of the genus 0 sector.

Since the connected $n$-point functions are given by the derivatives of $F = \sum_{g \geq 0} F_g$ w.r.t. $\tilde{J}$, this implies that all contributions in a genus expansion of the correlation functions for diagonal entries $\langle \phi_{kk} \rangle$ are finite and well-defined. The general non-diagonal correlation functions are discussed in section 4.2.2, and also turn out to be finite for arbitrary genus $g$ under the same conditions. Putting these results together we have established renormalizability of the model to all orders in a genus expansion, i.e.

**Theorem 2** All connected genus $g$ contributions to any given $n$-point function $\langle \phi_{i_1j_1} \ldots \phi_{i_nj_n} \rangle_c$ are finite and have a well-defined limit $N \to \infty$ for all $g$, under the above conditions.
Moreover, they can in principle be computed explicitly using the above formulas. This immediately extends to non-connected diagrams \( \langle \phi_{i_1j_1}...\phi_{i_nj_n} \rangle \). Furthermore, (95) shows that any contribution to \( F_g \) has order at least \( ((i\lambda_R)^2\alpha)^{2g-1} \). This implies (but is stronger than) perturbative renormalizability to all orders in \( \lambda_R \). This might not seem surprising in view of the results in [3–5], however note that the present model is more complicated than the \( \phi^4 \) model where the beta function was found to be zero at one loop for \( \Omega = 1 \) [16].

It is worth pointing out that only the genus 0 contribution requires renormalization, while all higher genus contributions are then automatically finite. This is very interesting because the genus 0 contribution can be obtained by various techniques in more general models, see e.g. [17]. A related approach was studied in [13, 14] without the oscillator potential.

It may appear surprising to find a well-defined \( \phi^3 \) model for real coupling, where the action is not bounded from below. This is possible because we first quantize the model for imaginary coupling, where the Kontsevich model is well-defined. The full genus expansion is then available, and the limit \( N \to \infty \) is under control upon proper renormalization. This allows in a second step to define the model for real coupling i.e. real \( i\lambda_R \), through analytic continuation. Similar behavior is well-known in the context of pure matrix models, which typically allow extension to seemingly unstable potentials [18]; this is usually interpreted as suppression of tunneling from a local minimum.

## 4.2.1 Exact renormalization and fine-tuning

The scaling (68) of the bare coupling is derived assuming that the one-point function (54) and therefore its coefficients \( \alpha \) and \( \lambda_R \) are kept fixed and independent of \( N \). This is the usual way to proceed in perturbative renormalization, and it would lead to new infinite renormalization at each order of perturbation theory, as can be seen by expanding (68) formally in terms of \( \lambda_R \).

On the other hand, we have the full renormalization in closed form available, which shows a simple leading scaling law for large \( N \). It is then natural to ask what would happen if we scale the bare coupling in a simpler way, e.g. respecting only the leading scaling

\[
i\lambda = c_\lambda \log(N)^{-2}, \quad Z = c_Z \log(N)^{-2}, \quad x = c_x \log(N)
\]

for some constant \( c_\lambda, c_Z, c_x \) rather than the exact form (68) etc. It turns out that this is not sufficient, and the renormalization must respect the exact form of (68) ff. rather than just their leading terms.

To see this, we determine the quantities \( (\lambda_R, \alpha, r, ...) \) for the simpler scaling (76), and check whether they also converge as \( N \to \infty \). This is obviously the case for
\( \lambda_R \sim \frac{c \lambda}{c^2 Z} \) and \( r \sim \frac{1}{c^2 Z} \), while \( \alpha \) is given by (67)

\[
\frac{1}{\alpha} = \frac{1}{xZ} - (i \lambda_R)^2 f_1 = \frac{1}{c_x c_Z} \log(N) + \frac{1}{2} \frac{c^2}{c_x c_Z} \frac{1}{(16 \pi^2 g^2)^3} \log(N) \quad (77)
\]

For this to have a well-defined limit \( N \to \infty \), the above scaling (76) is not sufficient, but the constants of proportionality must satisfy \( \frac{1}{c_x c_Z} = \frac{1}{2} \frac{c^2}{c_x c_Z} \frac{1}{(16 \pi^2 g^2)^3} \), and moreover the scaling must be refined to give the sub-leading constant (77).

This shows that even this relatively simple, solvable asymptotically free model has a rather severe “fine-tuning problem”, i.e. there is no obvious naturalness in the scaling of the bare parameters.

### 4.2.2 General \( n \)-point functions

Finally we show that all contributions in the genus expansion (and therefore perturbative expansion) of any \( n \)-point functions of the form

\[
\langle \phi_{i_1 j_1}, ..., \phi_{i_n j_n} \rangle \quad (78)
\]

have a well-defined and finite limit as \( N \to \infty \), provided the above renormalization conditions hold. The argument is the same as in [2], which we repeat here for convenience.

Recall that the insertion of a factor \( \tilde{\phi}_{ij} \) can be obtained by acting with \( 2i \lambda_R \frac{\partial}{\partial \tilde{J}_{ij}} \) on \( Z(\tilde{J}^2) \), resp. \( F_g(\tilde{J}^2) \). Now any given correlation function of type (78) involves only a finite set of indices \( i, j, ... \). Thus taking derivatives w.r.t. \( \tilde{J}_{ij} \) amounts to considering matrices \( \tilde{J} \) of the form

\[
\tilde{J} = \begin{pmatrix}
\text{diag}(\tilde{J}_1, ..., \tilde{J}_k) + \delta \tilde{J}_{k \times k} & 0 \\
0 & \text{diag}(\tilde{J}_{k+1}, ..., \tilde{J}_N)
\end{pmatrix},
\]

where \( k \) is chosen large enough such that all required variations are accommodated by the general hermitian \( k \times k \) matrix

\[
\tilde{J}_{k \times k} := \begin{pmatrix}
\text{diag}(\tilde{J}_1, ..., \tilde{J}_k) + \delta \tilde{J}_{k \times k}
\end{pmatrix}
\]

in (79), while the higher eigenvalues \( \tilde{J}_{k+1}, ..., \tilde{J}_N \) are fixed and given by (16). Therefore we can restrict ourselves to this \( k \times k \) matrix, which is independent of \( N \). As was shown in section 4.1, all \( F_g \) are in the limit \( N \to \infty \) smooth (in fact analytic) symmetric functions of the first \( k \) eigenvalues squared, hence of the eigenvalues of \( (\tilde{J}_{k \times k})^2 \). Such a function can always be written as a smooth (analytic) function of some basis of symmetric polynomials in the \( \tilde{J}_a^2 \), in particular

\[
F_g(\tilde{J}_1^2, ..., \tilde{J}_k^2) = f_g(\text{Tr}(\tilde{J}_{k \times k}^2), ..., \text{Tr}(\tilde{J}_{k \times k}^2)).
\]

18
This can be seen by approximating the analytic function $F_g(z_1, ..., z_k)$ at the point $z_i = \tilde{J}_i^2$ by a totally symmetric polynomial in the $z_i$, which correctly reproduces the partial derivatives up to some order $n$. According to a well-known theorem, that polynomial can be rewritten as a polynomial in the elementary symmetric polynomials, or equivalently as a polynomial in the variables $s_n := \sum z_i^n$, $n = 1, 2, ..., k$. This amounts to the rhs of (81).

In the form (81), it is obvious that all partial derivatives $\frac{\partial}{\partial \tilde{J}^2_i}$ of $F_g$ exist to any given order, and could be worked out in principle. This completes the proof that each genus $g$ contribution to the general (connected) correlators $\langle \phi_{i_1j_1}...\phi_{i_nj_n} \rangle$ is finite and convergent as $N \to \infty$.

### 4.3 Asymptotic behavior of the correlation functions

#### 4.3.1 $\langle \phi_{kk} \rangle$.

Using (53), the behavior of $\langle \phi_{kk} \rangle$ for large $k$ is dominated by $f_R(y_k)$, so that

$$
\langle \phi_{kk} \rangle_{g=0} \approx \frac{1}{2} \frac{i\lambda_R}{(16\pi^3 \theta^2)^3} y_k \log(y_k) \quad \text{for } k \to \infty.
$$

#### 4.3.2 $\langle \phi_{kl} \phi_{lk} \rangle$.

We can use (23) to obtain the genus 0 contribution to the 2-point function $\langle \phi_{kl} \phi_{lk} \rangle$ for $k \neq l$. Using (54) we obtain the exact expression

$$
\langle \phi_{kl} \phi_{lk} \rangle_{g=0} = -\frac{2\alpha^{-1}}{y_k + y_l} + 2(i\lambda_R)^2 \frac{f_R(y_k) - f_R(y_l)}{y_k^2 - y_l^2}.
$$

Note that the free case corresponds to $i\lambda_R = 0$ and $\alpha = -1$. Then indeed also the higher genus contributions vanish.

Consider the behavior for large $k \approx l$, which for large indices is dominated by the terms involving $f_R$:

$$
\langle \phi_{kl} \phi_{lk} \rangle \approx 2(i\lambda_R)^2 \frac{f_R(y_k) - f_R(y_l)}{y_k^2 - y_l^2}
$$

$$
\approx (i\lambda_R)^2 \frac{1}{y_k} \frac{d}{dy_k} f_R(y_k)
$$

$$
\approx (i\lambda_R)^2 \frac{1}{2(16\pi^3 \theta^2)^3} \frac{\log(y_k / J_0)}{y_k} \sim \frac{\log(k)}{k}
$$

for large $k \approx l$. It is worth pointing out that this 2-point function (and similar the 3-point function (90) below, etc.) is essentially determined by a function of a single variable $y$, which describes the dependence of the one-point function $\langle \phi_{kk} \rangle$ on the index $k$. This is characteristic for the genus 0 sector, which is essentially determined by an eigenvalue distribution.
4.3.3 $\langle \phi_{il}\phi_{kk} \rangle$.

As a further example, consider the 2-point function $\langle \phi_{il}\phi_{kk} \rangle$ for $k \neq l$, which vanishes in the free case. To compute it from the effective action, we need in principle

$$\langle \phi_{il}\phi_{kk} \rangle_c = \langle \tilde{\phi}_{il}\tilde{\phi}_{kk} \rangle - \langle \tilde{\phi}_{kk} \rangle \langle \tilde{\phi}_{il} \rangle = (2i\lambda_R)^2 \frac{\partial}{\partial \tilde{J}_l^2} \frac{\partial}{\partial \tilde{J}_k^2} (F_0 + F_1 + ...). \quad (85)$$

Even though this corresponds to a nonplanar diagram with external legs, it is obtained by taking derivatives of a closed genus 0 ring diagram. Therefore we expect that only $F_0$ will contribute, and indeed the derivatives of $F_1$ contribute only to order $\lambda^4_R$. For $k \neq l$, the genus zero contribution is

$$\langle \phi_{il}\phi_{kk} \rangle_c = (2i\lambda_R)^2 \frac{\partial}{\partial \tilde{J}_l^2} \frac{\partial}{\partial \tilde{J}_k^2} F_0$$

$$= \frac{1}{\sqrt{\tilde{J}_k^2 + 2b}} \frac{1}{\sqrt{\tilde{J}_l^2 + 2b}} \left( \frac{1}{\sqrt{\tilde{J}_k^2 + 2b} + \sqrt{\tilde{J}_l^2 + 2b}} \right)^2$$

$$\approx (i\lambda_R^2) \left( \frac{1}{\tilde{J}_k^2 + 2b} \right)^2 \quad (86)$$

as $k \approx l \to \infty$, using again (41). For $k = l$, we need

$$\langle \phi_{kk}\phi_{kk} \rangle_c = (2i\lambda_R)^2 \frac{\partial^2}{\partial (\tilde{J}_k^2)^2} F_0 \approx \frac{(2i\lambda_R)^2}{2} \frac{\partial}{\partial \tilde{J}_k} f_R(y; \delta \tilde{J}), \quad (87)$$

since $f_R(y)$ is the leading contribution for large $k$. Writing

$$\frac{d}{d\tilde{J}_k^2} f_R(y; \delta \tilde{J}) = \frac{dy}{d\tilde{J}_k^2} \frac{\partial}{\partial y} f_R(y; \delta \tilde{J}) + \frac{\partial}{\partial \tilde{J}_k} \left( \frac{y_k^2}{(\tilde{J}_k^2 + 2b)} \frac{1}{(\tilde{J}_k^2 + 2b) \sqrt{\tilde{J}_k^2 + 2b + (\tilde{J}_k^2 + 2b)}} \right), \quad (88)$$

we note that the first term (involving the sum) is dominant, while the second is only one term in a large sum. This then gives the same asymptotic behavior as the usual propagator,

$$\langle \phi_{kk}\phi_{kk} \rangle_c \approx \frac{(2i\lambda_R)^2}{2} \frac{\partial}{\partial y_k} f_R(y_k; \delta \tilde{J}) \approx \langle \phi_{kl}\phi_{lk} \rangle$$

for large $k$, using (84). On the other hand, it is very different from $\langle \phi_{il}\phi_{kk} \rangle_c$ given by (86). This should not be a surprise, since the latter corresponds to nonplanar diagrams as in figure 2.
Note that in (88), a derivative w.r.t. $\tilde{J}_k^2$ has essentially been replaced by a derivative w.r.t. $y \equiv y_k$. This is again characteristic for the genus 0 sector. In fact, $F_0$ can be obtained from the Dyson-Schwinger equation by making precisely this approximation.

### 4.4 The 3-point function

We can similarly use the exact expression (25) for the 3-point function to determine the asymptotic behavior of the 3-point function at genus 0:

$$\langle \phi_{kl} \phi_{lk} \phi_{kk} \rangle_c = 2i\lambda R \frac{1}{J_k^2 - J_l^2} \left( (\phi_{kk} - \phi_{ll})\phi_{kk} - (\phi_{kl} \phi_{lk}) \right)$$

$$\approx 2i\lambda R \frac{1}{J_k^2 - J_l^2} \left( (\phi_{kk} \phi_{kk})_c - (\phi_{kl} \phi_{lk}) \right)$$

$$\approx (2i\lambda R)^3 \frac{1}{y_k^2 - y_l^2} \frac{1}{2} \left( \frac{\partial}{\partial y_k^2} f_R(y; \delta \tilde{J}) - \frac{f_R(y_k) - f_R(y_l)}{y_k^2 - y_l^2} \right)$$

$$\approx (i\lambda R)^3 \frac{1}{2y_k dy_k} f_R(y_k; \delta \tilde{J})$$

$$\approx -(i\lambda R)^3 \frac{1}{4(16\pi^3 \theta^2)^3} \frac{1}{y_k \log(y_k/J_0)}$$  \hspace{1cm} (90)$$

for large $k \approx l$, using (86), (84) and (53). The same behavior is found for

$$\langle \phi_{kk} \phi_{kk} \phi_{kk} \rangle_c = (2i\lambda R)^3 \frac{\partial^3}{\partial (J_k^2)^3} F_0 \approx (2i\lambda R)^3 \frac{1}{2} \frac{\partial^2}{\partial (y_k^2)^2} f_R(y_k).$$ \hspace{1cm} (91)$$

up to a factor 2 which reflects the exchange symmetry between the external “legs” $\phi_{kl}$ and $\phi_{lk}$ for $k = l$. Combining (90) with (84) and (89), the 1PI vertex behaves like

$$\langle \phi_{kl} \phi_{lk} \phi_{kk} \rangle_{1PI} = \frac{1}{\langle \phi_{kl} \phi_{lk} \rangle_c} \frac{1}{\langle \phi_{kk} \phi_{kk} \rangle_c} \langle \phi_{kl} \phi_{lk} \phi_{kk} \rangle_c$$

$$\approx -2(i\lambda R)^3 (16\pi^3 \theta^2)^6 \left( \frac{1}{\log(y_k/J_0)} \right)^2 \sim - \left( \frac{1}{\log k} \right)^2$$ \hspace{1cm} (92)$$

for large $k \approx l$. This result is exact, because the higher genus contributions decay more rapidly as discussed in the next section. In particular, this establishes asymptotic freedom.

Several remarks are in order. First we note that this vertex function decays like $\frac{1}{(\log k)^2}$ rather than $\frac{1}{(\log k)^{7/2}}$, which would be found by a 1-loop computation as shown in section 6. Moreover, (92) is in nice agreement with (68), demonstrating that the 1PI vertex approaches the bare coupling $-\frac{i\lambda}{2}$ for $k \to N$. Finally, note that the
effective coupling constant for this asymptotic domain is $\frac{1}{\lambda R}$ rather than $\lambda_R$. This is clearly a purely “quantum” effect, which is again due to higher-order correction to the one-loop RG result (113).

4.5 Higher genus contributions

We illustrate here the stronger decay behavior of the higher-genus $n$-point functions, in the example of the one-point function. Consider

$$\langle \phi_{kk} \rangle_{g=1} = 2i\lambda_R \frac{\partial}{\partial \tilde{J}_k^2} F_1 = -\frac{2i\lambda_R}{24} \frac{\partial}{\partial \tilde{J}_k^2} \ln(1 - I_1)$$

$$= \frac{(i\lambda_R)^3}{12} \frac{\partial}{\partial \tilde{J}_k^2} f_{1,R}(\delta \tilde{J})$$

$$= \frac{(i\lambda_R)^3}{8} \frac{1}{(\tilde{J}_k^2 + 2b)^{5/2}} \left(1 + 2 \frac{\partial}{\partial \tilde{J}_k^2} b\right)$$

$$= \frac{(i\lambda_R)^3}{8} \frac{1}{(\tilde{J}_k^2 + 2b)^{5/2}} \left(1 - \frac{(i\lambda_R)^2 \alpha}{\sqrt{\tilde{J}_k^2 + 2b}}\right)$$

(93)

using (62) and (66). This asymptotically behaves like

$$\langle \phi_{kk} \rangle_{g=1} \sim \frac{1}{k^5}$$

(94)

for $k \to \infty$. Looking at (33), it is obvious that the higher-genus contributions are also decaying at least as rapidly as the genus 1 contribution (94), and similar results could be derived for the $n$-point functions.

Finally, it follows from (63) that each term in $F_g$ contains the factor

$$F_g \sim ((i\lambda_R)^2 \alpha)^2 (g-1)^{+} \Sigma \ell_p$$

(95)

for $g \geq 2$, which is at least $\alpha^{2(g-1)+1}$. Hence $(i\lambda_R)^2 \alpha$ is the parameter which controls the genus expansion.

5 Further aspects

Structural remarks

We briefly add some heuristic remarks which might shed new light on the formal results obtained above.
The model considered here is characterized by a function $F$ of $\tilde{J}$ which is invariant under conjugation with $U(N^3)$. This implies in particular that $F = F_N(\tilde{J}_k)$ is a totally symmetric function of the eigenvalues $\tilde{J}_k$, i.e. it is a function on the quotient space $\mathbb{R}^{N^3}/S_{N^3}$ where $S_{N^3}$ denotes the permutation group. Since the observables are obtained by taking partial derivatives w.r.t. $\tilde{J}$, we are interested in

$$W_k(\tilde{J}) = \frac{\partial}{\partial J_k} F_N(\tilde{J}),$$

$$W_{k,l}(\tilde{J}) = \frac{\partial}{\partial J_k} \frac{\partial}{\partial J_l} F_N(\tilde{J}),$$

etc. Renormalizability requires that all these derivatives exist and have a well-defined limit $N \to \infty$, hence that $F_N(\tilde{J}_i)$ converges to an infinitely differentiable function $F(\tilde{J}_i)$. This must hold at the point $\tilde{J}$ with eigenvalues given by (16), or preferably in some “good” neighborhood $\mathcal{U} \ni \tilde{J}$ in $\mathbb{R}^{N^3}$, with an appropriate limit $N \to \infty$. Furthermore, these partial derivatives should have suitable decay properties such as indicated above.

Now consider the dependence of $W_k(\tilde{J})$ on the index $k$. It is a physical requirement that this dependence on the indices is mild\(^8\). This can be understood analytically as follows. Note that $W_k(\tilde{J})$ is related to $W_l(\tilde{J})$ by exchanging the arguments $\tilde{J}_k$ and $\tilde{J}_l$, i.e. by applying the permutation operator $\sigma_{k,l}$ on the space $\mathbb{R}^{N^3}$ of $\tilde{J}_k$,

$$W_k = W_l \circ \sigma_{k,l}. \quad (97)$$

This means that the index dependence may be traded for a “small” change (a permutation) of the eigenvalues. Since the eigenvalues are ordered and approach a simple distribution, it is plausible that $\sigma_{k,l}$ respects the neighborhood $\mathcal{U}$. Smoothness in $\mathcal{U}$ would then naturally imply that the dependence on the indices is mild. Indeed, we found explicitly that the index dependence at genus 0 becomes translated into the dependence of a smooth function $W(y)$ (43) on the variable $y$.

**Extension to $\Omega \neq 1$**

Once a suitable domain $\mathcal{U}$ is established where $F[\tilde{J}]$ is smooth with suitable decay properties of its partial derivatives, then the following strategy to extend our results to $\Omega \neq 1$ can be envisaged. The partition function for $0 \neq \Omega \neq 1$ can be obtained from the results for $\Omega = 1$ using

$$Z[\tilde{J}] = \langle e^{\text{Tr} \tilde{x}_i \phi} \tilde{x}_i \phi \rangle_{\Omega = 1} = e^{\text{Tr} \tilde{x}_i \frac{\partial}{\partial \tilde{x}_i} \tilde{x}_i \frac{\partial}{\partial \tilde{x}_i} \tilde{x}_i} Z[\tilde{J}_{\Omega = 1}] = e^{\text{Tr} \tilde{x}_i \frac{\partial}{\partial \tilde{x}_i} \tilde{x}_i \frac{\partial}{\partial \tilde{x}_i} \tilde{x}_i} e^{F[\tilde{J}]} =: e^{F[\tilde{J}]} \quad (98)$$

\(^8\)some mild singularities for coinciding indices might be allowed however
for small $\epsilon$, accompanied by a change of wavefunction normalization. Hence we should consider the operator

$$\Delta_J := Tr[\tilde{x}_i, \frac{\partial}{\partial J^2}] [\tilde{x}_i, \frac{\partial}{\partial J^2}]$$

acting on functions of $\tilde{J}$. It does not commute with $U(N^3)$, hence $Z[\tilde{J}]$ will be a function of $\tilde{J}$ which no longer depends on the eigenvalues only. We have established in this paper that $Z[\tilde{J}]_{\Omega=1}$ is a well-defined, infinitely differentiable function (after subtracting a possible infinite constant from $F$). The question of renormalizability for $\Omega \neq 1$ is whether $F[\tilde{J}]$ is also a well-defined, infinitely differentiable function, possibly after further renormalization. To establish this using the methods of the present paper might therefore be feasible, by studying the operator $\Delta_J$ and establishing careful estimates on the partial derivatives of $F[\tilde{J}]_{\Omega=1}$ and their asymptotic behavior for large $N$. However, we will not attempt to do this in the present paper.

### Remarks on the relation with string theory

The Kontsevich model has been related to string theory in [19] as follows. The matrix $X_{ij}$ of the Kontsevich model is interpreted as coefficient of the open string field, more precisely the tachyon, connecting the (Liouville) $D$-brane with label $i$ to the $D$-brane with label $j$. The eigenvalues $\tilde{M}_i$ of the external potential in the Kontsevich model are interpreted as boundary cosmological constants on the brane with label $i$, and the Kontsevich model (26) describes the (topological sector of) open string field theory in this situation.

Applying this interpretation to our model, we are led to a picture of open string tachyons in string field theory with $N^3$ D-branes, with specific cosmological constant $J_i \sim i_1 + i_2 + i_3$ on the brane $i = (i_1, i_2, i_3)$. The fact that our model is renormalizable implies that the correlators become essentially smooth functions of these 3 coordinates $i_1, i_2, i_3$, with a well-defined large $N$ limit. This could be interpreted by saying that the endpoints $i, j$ of the open strings effectively live in 3 dimensions with coordinates $i_1, i_2, i_3 \geq 0$, forming a 3-dimensional wedge $\mathbb{R}_+^3$ with a potential determined by $J_i$. In other words, 3 extra dimensions appear from the string point of view by some kind of stringy “deconstruction” of dimensions. On the other hand, we have the interpretation as 6-dimensional non-commutative field theory. This points to interesting directions for further studies.

### 6 Perturbative computations

We write the bare action (6) as

$$S = Tr \left( \frac{1}{4} (J \phi^2 + \phi^2 J) + \frac{i\lambda}{3!} \phi^3 - (i\lambda) A \phi \right)$$
The finite kinetic term \((G_R)_{i;k}^{j;l} \phi^i \phi^k + \frac{i \lambda_R}{3!} \phi^3\) defines the renormalized propagator
\[ \Delta_{i;k}^{j;l}(\phi^i \phi^k) = \delta_{i}^{j} \delta_{k}^{l} \frac{2}{J_i + J_j} = \delta_{i}^{j} \delta_{k}^{l} \frac{1/(4 \pi^2 \theta)}{1 + \frac{1}{(\mu_R^2 \theta + 3)}}, \]

The counterterms are collected in
\[ \delta S = Tr \left( - (i \lambda_R) Z \Lambda \phi + \frac{1}{4} (\delta J \phi^2 + \phi^2 \delta J) + \frac{i \delta \lambda}{3!} \phi^3 \right), \]

where
\[ \lambda_R = Z^{-1} \lambda, \]
\[ \delta \lambda = \lambda_R (Z - 1) \]

is part of the counter-term, and \(\delta \mu^2 = (\mu^2 - \mu_R^2)\). It is then easy to see that the usual power counting rules apply (with suitable extensions to the case of higher genus [20]), where \(N\) plays the role of the cutoff \(\Lambda^2\). This can be seen in the following 1-loop examples:

**3-point function** In 6 dimensions, the interaction vertex requires renormalization, induced by the planar one-loop 1PI graph (without external legs) in figure 1. This gives
\[
\langle \phi_{ij} \phi_{jk} \phi_{ki} \rangle_{1PI} = - \frac{i \lambda_R}{2} + \left( \frac{-i \lambda_R}{2} \right)^3 \sum_i \frac{2}{J_k^R + J_i^R J_j^R + J_l^R} \frac{2}{J_l^R + J_i^R} - \frac{i \delta \lambda}{2}
\approx - \frac{i \lambda_R}{2} + \left( \frac{-i \lambda_R}{2} \right)^3 \sum_i \frac{1}{(J_k^R + J_i^R)^3} \frac{1}{2} + \text{finite}
\approx - \frac{i \lambda_R}{2} + \left( \frac{-i \lambda_R}{2} \right)^3 \frac{1}{(16 \pi^2 \theta^2)^3} \sum_i \frac{1}{(l + m)^3} - \frac{i \delta \lambda}{2} + \text{finite}
\approx - \frac{i \lambda_R}{2} + \left( \frac{-i \lambda_R}{2} \right)^3 \frac{1}{(16 \pi^2 \theta^2)^3} \log \frac{N + m}{8m} - \frac{i \delta \lambda}{2} + \text{finite}
\]
All nonplanar contributions are finite. This gives the counterterm to the coupling constant
\[ i\delta\lambda = -\frac{(i\lambda_R)^3}{(16\pi^3\theta^2)^3} \log \frac{N + m}{8m} + \text{finite} \] 
so that
\[ (i\lambda) = (i\lambda_R)(1 + \frac{(i\delta\lambda)}{(i\lambda_R)}) = \frac{(i\lambda_R)}{1 + \frac{(i\lambda_R)^2}{(16\pi^3\theta^2)^3} \log \frac{N}{m}} + O(\lambda_R^5). \] 
The minus sign indicates asymptotic freedom. However, the last formula (108) is only suggestive, and such a one-loop result should be used with caution. Note that we could equally well write
\[ (i\lambda) = \frac{(i\lambda_R)}{\left(1 + \frac{1}{2} \frac{(i\lambda_R)^2}{(16\pi^3\theta^2)^3} \log \frac{N}{m}\right)^2} + O(\lambda_R^5), \] 
which is in fact agrees much better with the exact scaling (68) of the bare coupling. A better way to understand the coupling constant renormalization is to determine its dependence on the “scale” \( m \), i.e. the running coupling constant
\[ g(m) = -i\lambda_R(m) = 2\langle \phi_{ij}\phi_{jk}\phi_{ki} \rangle_{1PI} \] 
for \( i \approx j \approx k = m \) (103). An extra factor 2 is inserted for convenience. The corresponding one-loop beta function can be obtained from (106),
\[ \beta := 2m \frac{\partial \langle \phi_{ij}\phi_{jk}\phi_{ki} \rangle_{1PI}}{\partial m} = \frac{g(m)^3}{(16\pi^3\theta^2)^3} m \frac{\partial \log \frac{N}{m}}{\partial m} = -\frac{g(m)^3}{(16\pi^3\theta^2)^3} \] 
indicating asymptotic freedom. This gives
\[ \frac{dg(m)}{g(m)^3} = -\frac{1}{(16\pi^3\theta^2)^3} \frac{dm}{m} \] 
which can be integrated to give the running (1PI) coupling constant
\[ g(m)^2 = \frac{g(m_0)^2}{1 + \frac{2g(m_0)^2}{(16\pi^3\theta^2)^3} \log \frac{m}{m_0}}. \]
This decreases with increasing scale $m$, which means asymptotic freedom. However, note that the exact scale dependence $g(m) \sim -\frac{1}{(\log m)^2}$ for large $m$ which was determined in (92) is not correctly reproduced by this one-loop RG computation. This shows that the common practice of using the 1-loop RG results for the running coupling constant may not be sufficiently accurate for large scales.

It is worth pointing out that the coupling constant runs here even at one-loop, in contrast to the case of the $\phi^4$ model in 4 dimensions [16].

**1-point function** The one-loop contribution to the 1-point function gives

$$
\langle \phi_{ii} \rangle_{1\text{-loop}} = \frac{i\lambda_R Z_\lambda}{J_i} A_i - \frac{i\lambda_R}{2} \sum_k \frac{2}{J_i + J_k}
$$

$$= -\frac{i\lambda_R}{J_i} \left( -Z_\lambda A_i + \frac{1}{16\pi^3\theta^2} \sum_k \frac{1}{\hat{\lambda} + k + 3 + \mu_R^2\hat{\theta}} \right).
$$

To proceed, we expand

$$h(\hat{\lambda}) := \sum_k \frac{1}{\hat{\lambda} + k + 3 + \mu_R^2\hat{\theta}} = h(0) + (\hat{\lambda}) h'(0) + \frac{1}{2} (\hat{\lambda})^2 h''(0) + h_R(\hat{\lambda})
$$

where $h_R(\hat{\lambda})$ is a finite nontrivial function of $\hat{\lambda}$, and

$$h(0) = \sum_k \frac{1}{k + \mu_R^2\hat{\theta} + 3} = (-6 \log 2 + \frac{9}{2} \log 3) N^2
$$

$$+ (-6(\mu_R^2\hat{\theta} + 3) \log 2 + 3(\mu_R^2\hat{\theta} + 3) \log 3) N + \frac{1}{2}(\mu_R^2\hat{\theta} + 3)^2 \log N,
$$

$$h'(0) = -\sum_k \frac{1}{(k + \mu_R^2\hat{\theta} + 3)^2} = -(16\pi^3\theta^2)^2 f_0 - (16\pi^3\theta^2)^3 (3 + \mu_R^2\hat{\theta}) f_1
$$

$$= -(6 \log(2) - 3 \log(3)) N + \frac{3 + \mu_R^2\hat{\theta}}{2} \log(N),
$$

$$h''(0) = 2 \sum_k \frac{1}{(k + \mu_R^2\hat{\theta} + 3)^3} = -(16\pi^3\theta^2)^3 2 f_1 = \log(N)
$$

up to finite corrections, using the results of section 4.1.1. We note in particular that the $\hat{\lambda}$-dependent term $(\hat{\lambda}) h'(0) + \frac{1}{2} (\hat{\lambda})^2 h''(0)$ in (114) forces us to introduce a corresponding counterterm to the action as in (9), $A = a_0 + a_1 J + a_2 J^2$. As discussed in section 2, this is no longer equivalent to an infinite shift (10) of $\phi$. Taking this into account we have

$$\langle \phi_{ii} \rangle_{1\text{-loop}} = -\frac{i\lambda_R}{J_i} \left( -(a_0 + a_1 J + a_2 J^2) Z_\lambda
$$

$$+ \frac{1}{16\pi^3\theta^2} (h(0) + (\hat{\lambda}) h'(0) + \frac{1}{2} (\hat{\lambda})^2 h''(0) + h_R(\hat{\lambda})) \right).
$$
Finiteness and the condition $\langle \phi_{00} \rangle = 0$ implies to lowest order

\begin{align*}
a_2 &= \frac{1}{(16\pi^2\theta^2)^3} \frac{1}{2} \log N = -f_1 + \text{finite}, \\
a_1 &= -(16\pi^2\theta^2)(\mu_R^2\theta + 3)a_2 + \frac{1}{(16\pi^2\theta^2)^2} h'(0) = -f_0 + \text{finite}, \\
a_0 &= \frac{1}{16\pi^2\theta^2} h(0) - (8\pi^2\theta^2)(\mu_R^2\theta + 3)a_1 - (8\pi^2\theta^2)^2(\mu_R^2\theta + 3)^2 a_2
\end{align*}

up to finite corrections. These renormalization conditions guarantee that the one-point function $\langle \phi_{ii} \rangle$ has a well-defined and nontrivial limit $N \to \infty$. In particular, (119) and (14) imply

\begin{equation}
x = \sqrt{1 + \frac{(i\lambda_R)^2}{(16\pi^2\theta^2)^3} \log N} = 1 + \frac{1}{2} \frac{(i\lambda_R)^2}{(16\pi^2\theta^2)^3} \log N, \tag{122}
\end{equation}

to lowest order, and (120) together with (17) gives

\begin{equation}
\delta \mu^2 \theta = \frac{2(i\lambda_R)^2}{(16\pi^2\theta^2)} f_0 + \text{finite}. \tag{123}
\end{equation}

This is consistent with the exact result (72).

Finally, it is interesting to consider the behavior of $\langle \phi_{ii} \rangle$ for large $i$. After imposing the above renormalization conditions, we observe that the dominating term in (118) is $\frac{i\lambda_R}{f} \frac{1}{2} (\log N)$. Here $h''(0) \sim \log(N)$ should more properly be replaced by $\log(N/\tilde{\lambda})$, which implies

\begin{equation}
\langle \phi_{ii} \rangle \sim \tilde{\lambda} \log(\tilde{\lambda}) \tag{124}
\end{equation}

for large $i$. This is in agreement with (82).

**2-point function**  

Next we compute the leading contribution to the 2-point function $\langle \phi_{ll} \phi_{kk} \rangle$ for $l \neq k$, which vanishes at tree level. The leading contribution comes from the nonplanar graph in figure 2, which gives

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{fig2.png}
\caption{one-loop contribution to $\langle \phi_{ll} \phi_{kk} \rangle$}
\end{figure}
\[ \langle \phi_{ll} \phi_{kk} \rangle = \langle \phi_{kk} \rangle \langle \phi_{ll} \rangle + \frac{1}{4} \frac{(i\lambda_R)^2}{J_k J_l} \left( \frac{2}{J_k + J_l} \right)^2 \]  

(125)

(for \( l \neq k \)) indicating the symmetry factors, where the disconnected contributions are given by (114). This is consistent with the result (86) obtained from the Kontsevich model approach. Note that the counterterm \( \delta J \) does not enter here.

Similarly, the leading contribution to the 2-point function \( \langle \phi_{kl} \phi_{lk} \rangle \) for \( l \neq k \) has the contribution indicated in figure 3, involving also the counterterm \( \delta J \). This gives

\[ \langle \phi_{kl} \phi_{lk} \rangle_{\text{1-loop}} = \frac{2}{J_k^R + J_l^R} - 2(i\lambda_R) \frac{\langle \phi_{kk} + \phi_{ll} \rangle}{(J_k^R + J_l^R)^2} \]

\[ + \frac{4}{(J_k^R + J_l^R)^2} \left( \sum_j \frac{(i\lambda_R)^2}{J_k^R + J_j^R J_l^R + J_j^R} \right) \left( \frac{1}{2} \delta J_l + \delta J_k \right). \]  

(126)

The first term is the free propagator, the next term the tadpole contributions, and the last term the one-loop contribution in figure 3 with counterterm \( \delta J \).

We have to adjust the parameters such that the result is well-defined and non-trivial. Using (116) and (117), we can write

\[ \sum_j \frac{1}{J_k^R + J_j^R J_l^R + J_j^R} = \frac{1}{(16\pi^2 \theta^2)^2} \sum_j \left( \frac{1}{(j + \mu_R^2 \theta + 3)^2} - \frac{k + l}{(j + \mu_R^2 \theta + 3)^3} \right) + \text{finite} \]

\[ = \frac{1}{(16\pi^2 \theta^2)^2} \left( - h'(0) - \frac{1}{2} h''(0) + \text{finite} \right) \]  

(127)

Therefore

\[ \delta J_l + \delta J_k = \frac{2(i\lambda_R)^2}{(16\pi^2 \theta^2)^2} \left( - h'(0) - \frac{1}{2} h''(0) \right) + \text{finite}, \]  

(128)

which using (116), (117) implies

\[ (Z - 1)(k + l) = 2(i\lambda_R)^2 (k + l) f_1 \]  

(129)
and

\[ Z(\delta \mu^2 \theta) + (Z - 1)(3 + \mu^2 R) = \frac{2(i\lambda R)^2}{(16\pi^3 \theta^2)} f_0 + 2(i\lambda R)^2(3 + \mu^2 R) f_1 \]

(130)

up to finite corrections. Hence we obtain the lowest order mass and wavefunction renormalization:

\[
Z = 1 + 2(i\lambda R)^2 f_1 = \frac{1}{\left(1 + \frac{1}{2} \frac{(i\lambda R)^2}{(16\pi^3 \theta^2) \log N}\right)^2 + O(\lambda^4_R)}
\]

\[
\delta \mu^2 \theta = \frac{2(i\lambda R)^2}{(16\pi^3 \theta^2)} f_0
\]

(131)

up to finite corrections, in agreement with (123).

Note that in 8 or higher dimensions, divergent mixed terms \((k)(l)\) would occur in (127) which can no longer be absorbed. Then the model is no longer renormalizable, as in the commutative case.

7 Summary and discussion

We have shown that the selfdual NC \(\phi^3\) model in 6 dimensions can be renormalized and essentially solved in terms of a genus expansion, by using the Kontsevich model. This provides a model which contains essentially the full complexity of renormalization of a not super-renormalizable asymptotically free quantum field theory, while being solvable and hence fully under control. In principle, all \(n\)-point functions can be computed in a genus expansion, and we give explicit expressions for the 1-, 2-, and some 3-point functions.

In particular, we were able to determine exactly the RG flow of the bare parameters as a function of the cutoff \(N\), as well as the running of the “physical” coupling constant i.e. the 1PI 3-point function. As in the case of 2 and 4 dimensions [1, 2], it turns out that the renormalization is fully determined by the genus 0 sector. In particular, we can compare the exact results with the standard perturbative methods. For example, it turns out that the 1-loop beta function for the coupling constant gives roughly the correct behavior and correctly predicts asymptotic freedom, but wrongly gives a \((\log N)^{-1}\) dependence on the scale as opposed to the correct \((\log N)^{-2}\) dependence.

We also show that the model has a critical surface defined by \(\alpha = 0\), which separates 2 different phases. One phase has the expected “physical” properties, while in the other some modes become unstable.

It is very remarkable that a nontrivial, asymptotically free 6-dimensional NC \(\phi^3\) field theory allows such a detailed analytical description. There is no commutative
analog where this has been achieved to our knowledge. Therefore this model can
serve as a testing ground for various ideas and methods for renormalization. It also
shows that the noncommutative world in some cases is more accessible to analytical
methods than the commutative case. While the techniques used in this paper
are more–or–less restricted to the $\phi^3$ interaction, it is worth pointing out that the
renormalization is determined by the genus 0 contribution only, which is accessible
in a wider class of models; see also [13, 14] in this context.

One of the open problems is the lack of control over the sum over all genera $g$. We have not shown that the sum over $g$ converges in a suitable sense, which would amount to a full construction of the model. Furthermore, it would be extremely interesting to extend the analysis beyond the case of $\Omega = 1$. We propose a strategy in section 5 how such an extension might be possible, and we also comment on a relation with open string field theory.
