Abstract. In Li (2011, Example 2.2), the notion of a multi-type continuous-state branching process (MCSBP) was introduced with a finite number of types, with the countably infinite case being proposed in Kyprianou and Palau (2017). One may consider such processes as a super-Markov chain on a countable state-space of types, which undertakes both local and non-local branching. In Kyprianou and Palau (2017) it was shown that, for MCSBPs, under mild conditions, there exists a lead eigenvalue which characterises the spectral radius of the linear semigroup associated to the process. Moreover, in a qualitative sense, the sign of this eigenvalue distinguishes between the cases where there is local extinction and exponential growth. In this paper, we continue in this vein and show that, when the number of types is finite, the lead eigenvalue gives the precise almost sure rate of growth of each type. This result matches perfectly classical analogues for multi-type Galton–Watson processes.

1. Introduction

Let \( d \in \mathbb{N} \) be a natural number and put \( E = \{1, \ldots, d\} \). For \( \mathbf{x} = (x_1, \ldots, x_d) \in \mathbb{R}^d \) we use the notation \( x(i) := x_i \) for \( i \in E \) and denote by \( \|\mathbf{x}\| \) the Euclidean norm. We consider a multi-type continuous state branching process with \( d \) types with branching mechanism \( \psi \), henceforth referred to as a \( \psi \)-MCSBP. This is to say, we are interested in a \([0, \infty)^d\)-valued strong Markov process \( \mathbf{X} := (\mathbf{X}_t, t \geq 0) \), with probabilities \( \{\mathbb{P}_x, x \in \mathbb{R}^d_+\} \) such that the following branching property hold: for all \( \mathbf{x}, \mathbf{y} \in \mathbb{R}^d_+ \),

\[
\mathbb{E}_{\mathbf{x} + \mathbf{y}} \left[ e^{-\langle f, \mathbf{X}_t \rangle} \right] = \mathbb{E}_\mathbf{x} \left[ e^{-\langle f, \mathbf{X}_t \rangle} \right] \mathbb{E}_\mathbf{y} \left[ e^{-\langle f, \mathbf{X}_t \rangle} \right], \quad t \geq 0, \quad f \in \mathbb{R}^d_+.
\]

2000 Mathematics Subject Classification. 60J68, 60J80.

Key words and phrases. Continuous-state branching processes, non-local branching mechanism, super Markov chain, strong law of large numbers.
Its branching mechanism, a vectorial function \( \psi : E \times \mathbb{R}_+^d \to \mathbb{R}^d \) such that
\[
\psi_i(u) := -\langle u, B_e_i \rangle + c_i u_i^2 + \int_{\mathbb{R}_+^d} (e^{-\langle u, z \rangle} - 1 + u_i(z_i \wedge 1)) \mu_i(\mathrm{d}z), \quad u \in \mathbb{R}_+^d, i \in E,
\]
where \( c_i \in \mathbb{R}_+ \), \( B \) is a \( d \times d \) matrix such that \( B_{i,j} \mathbf{1}_{i \neq j} \in \mathbb{R}_+^d \), \( e_1, \cdots, e_d \) is the natural basis in \( \mathbb{R}^d \), and \( \mu_i \) is a measure concentrated on \( \mathbb{R}_+^d \setminus \{ 0 \} \) such that
\[
\int_{\mathbb{R}_+^d} \left[ \| z \wedge \| z \|^2 + \sum_{j \in E} 1_{\{ j \neq i \}} z_j \right] \mu_i(\mathrm{d}z) < \infty.
\]
The process \( X \) is characterized by its Laplace transform:
\[
\mathbb{E}_x \left[ e^{-\langle f, X(t) \rangle} \right] = e^{-\langle x, \psi(t, f) \rangle}, \quad x, f \in \mathbb{R}_+^d, \ t \in \mathbb{R}_+,
\]
where, for any \( f \in \mathbb{R}_+^d \), the continuous differentiable function
\[
t \mapsto \psi(t, f) = (v_1(t, f), \cdots, v_d(t, f))^T,
\]
is the unique locally bounded non-negative solution to the system of integral equations
\[
v_i(t, f) = f_i - \int_0^t \psi_i(\varphi(s, f)) \mathrm{d}s, \quad i \in E.
\]
According to Barczy et al. (2015), this process can be seen as a strong solution of a stochastic differential equation (SDE). More precisely, let \( W_t \) be a \( d \)-dimensional standard Brownian motion, and for each \( i \in E \), let \( N_i \) be a Poisson random measure on \( \mathbb{R}_+ \times \mathbb{R}_+^d \times \mathbb{R}_+ \) with intensity measure \( \mathrm{d}s \mu_i(\mathrm{d}z) \mathrm{d}r \), and denote by \( \tilde{N}_i \) its compensated measure. Suppose that \( W \) and \( (N_i)_{i \in E} \) are independent of each other. Then, a MCSBP with branching mechanism \( \psi \) is characterized as the unique \( \mathbb{R}_+^d \)-valued strong solution to the SDE
\[
X_t = X_0 + \int_0^t B X_s \mathrm{d}s + \sum_{i \in E} e_i \int_0^t 2 c_i X_{s,i} \mathrm{d}W_{s,i} + \sum_{i \in E} \int_0^t \int_{\mathbb{R}_+^d} \int_0^\infty z 1_{\{ z \leq X_{s,i} \}} \tilde{N}_i(\mathrm{d}s, \mathrm{d}z, \mathrm{d}r),
\]
where the matrix \( B \) is given by
\[
B_{i,j} = B_{i,j} + \int_{\mathbb{R}_+^d} (z_i - \delta_{i,j})^+ \mu_j(\mathrm{d}z).
\]
Moreover, they proved in Barczy et al. (2015, Formula (2.15) and the later computations) that \( \psi \) can be written as
\[
\psi_i(u) = -\langle u, B e_i \rangle + c_i u_i^2 + \int_{\mathbb{R}_+^d} (e^{-\langle u, z \rangle} - 1 + \langle u, z \rangle) \mu_i(\mathrm{d}z), \quad u \in \mathbb{R}_+^d, i \in E.
\]
Remark 1.1. Thanks to the relation between \( B \) and \( \tilde{B} \), when we write the branching mechanism as in (1.4), the matrix \( B \) satisfies
\[
\int_{\mathbb{R}_+^d} z(i) \mu_j(\mathrm{d}z) \leq B_{ij} \quad \text{for all } i \neq j.
\]
Remark 1.2. If we regard $E$ as the space where particles located, the model we described above can be seen as a special case of a superprocess in which the associated Markov movement is that of a Markov chain on $E$. Indeed, for such a process, from e.g. Dynkin (1991), the log-Laplace semigroup, $V_t : \mathbb{R}_+^d \rightarrow \mathbb{R}_+^d$, which similarly to (1.1), satisfies $\langle x, V_t f \rangle = -\log \mathbb{E}_x [e^{-\langle f, X_t \rangle}]$, for $f, x \in \mathbb{R}_+^d$, and is the unique solution to

$$V_t f(i) = [e^{Qf}](i) - \int_0^t e^{(t-s)Q}\psi_i(V_s f)ds$$

where $f = (f(1), \ldots, f(d))^T \in \mathbb{R}_+^d$ and $Q$ is the infinitesimal generator of the associated Markov chain. Note that a straightforward manipulation in the spirit of Theorem 3.1.2 of Dynkin (2002) implies that

$$V_t f(i) = f(i) + \int_0^t [QV_s f](i) - \int_0^t \psi_i(V_s f)ds = f(i) + \int_0^t \langle V_s f, Q^T e_i \rangle - \int_0^t \psi_i(V_s f)ds,$$

where $Q^T$ is the transpose matrix of $Q$. In turn, we note that this is equivalent to the unique semigroup evolution that solves (1.2), albeit that the branching mechanism

$$\tilde{\psi}_i(u) := -\langle u, Q^T e_i \rangle + \psi_i(u) \quad u \in \mathbb{R}_+^d, \quad i \in E.$$

We therefore suppose in the remaining part of this paper that $\{X_t, t \geq 0\}$ is a $\psi$-MCSBP. Denote by $M(t) := (M(t)_{i,j})_{d \times d}$ the matrix with elements

$$M(t)_{i,j} := \mathbb{E}_{e_i} \left[ \langle e_j, X_t \rangle \right], \quad i, j \in E, \quad t \geq 0.$$

By Barczy et al. (2015, Lemma 3.4) we have

$$M(t) = e^{tB^T}, \quad t \geq 0,$$

where $B^T$ is the transpose of $B$. Observe that for any initial vector $x_0$ and any $x \in \mathbb{R}_+^d$,

$$\mathbb{E}_{x_0} \left[ \langle x, X_t \rangle \right] = x_0^T M(t)x, \quad t \geq 0.$$

Moreover, by (1.3) and the Itô calculus, for all $x \in \mathbb{R}_+^d$ and $s \leq r \leq t$, we obtain

$$\langle M(t-r)x, X_r \rangle = \langle M(t-s)x, X_s \rangle + \sum_{i \in E} \int_s^r \int_s^r [M(t-u)x]_i \sqrt{2e_iX_{u,j}} dW_{u,i}$$

$$+ \sum_{i \in E} \int_s^r \int_{\mathbb{R}^d_+} \int_{0}^{\infty} \langle M(t-u)x, z \rangle 1_{\{t \leq X_{u,i} < \}} \tilde{N}_i(du, dz, dl).$$

In particular, if we take $r = t$, we get the following equation

$$\langle x, X_t \rangle = \langle M(t-s)x, X_s \rangle + \sum_{i \in E} \int_s^t \int_s^t [M(t-u)x]_i \sqrt{2e_iX_{u,j}} dW_{u,i}$$

$$+ \sum_{i \in E} \int_s^t \int_{\mathbb{R}^d_+} \int_{0}^{\infty} \langle M(t-u)x; z \rangle 1_{\{t \leq X_{u,i} < \}} \tilde{N}_i(du, dz, dl).$$

A vector $u \in \mathbb{R}^d$ is called a $\lambda$-right (resp. left) eigenvector if for all $t \geq 0$,

$$M(t)u = e^{\lambda t}u, \quad \text{resp. } u^T M(t) = e^{\lambda t}u^T.$$

If $u$ is a $\lambda$-right eigenvector, define

$$W_t^\lambda (u) := e^{-\lambda t} \langle u, X_t \rangle, \quad t \geq 0.$$
Then it was shown in Proposition 3 of Kyprianou and Palau (2017) that if $u$ is a $\lambda$-right eigenvector with $\lambda \in \mathbb{R}$, then for any $x \in \mathbb{R}^d$, $\{W^t_u(u), t \geq 0\}$ is a martingale under $\mathbb{P}_x$.

Suppose that $M(t)$ is irreducible (exists $t_0 > 0$ such that $M(t_0)_{i,j} > 0$ for all $i, j \in E$). The Perron-Frobenius theory implies that there exist $\lambda_1 \in \mathbb{R}$ and right and left associated eigenvectors $\phi, \hat{\phi} \in \mathbb{R}^d_+$ with all coordinates strictly positive such that $M(t)\phi = e^{\lambda_1 t} \phi$ and $\hat{\phi}^T M(t) = e^{\lambda_1 t} \hat{\phi}^T$, for all $t \geq 0$. We note from (1.6) that this is equivalent to the statement that $\phi$ and $\hat{\phi}$ are right and left eigenvectors for $B^T$ with common eigenvalue $\lambda_1$. For convenience we shall normalise $\phi$ and $\hat{\phi}$ such that $\langle \phi, 1 \rangle = 1 = \langle \hat{\phi}, \hat{\phi} \rangle$. Moreover, any other eigenvalue $\lambda$ satisfies $\lambda_1 > \Re(\lambda)$ and

$$\lim_{t \to \infty} M(t)e^{-\lambda_1 t} = P := (\phi_i \hat{\phi}_j)_{i,j \in E}.$$ 

In addition, Barczy and Pap (2016, Lemma A.3) proved that there exist $c_1, c_2, c_3 > 0$ such that

$$\|M(t)e^{-\lambda_1 t} - P\| \leq c_1 e^{-c_2 t} \quad \text{and} \quad \|M(t)\| \leq c_3 e^{\lambda_1 t} \quad \text{for all } t \in \mathbb{R}_+.$$  

(1.9)

In order to simplify notation, we will denote by

$$W_t := W^t_\lambda(\phi) = e^{-\lambda_1 t} \langle \phi, X_t \rangle, \quad t \geq 0.$$ 

(1.10)

Observe that $W_t$ is a non-negative martingale and has a limit a.s. that we will denote by $W_\infty$.

We say that the $\psi$-MCSBP is subcritical, critical, or supercritical according as $\lambda_1 < 0$, $\lambda_1 = 0$, or $\lambda_1 > 0$. This classification is consistent with the corresponding classification for single-type continuous state branching processes, see, e.g., Li (2011, Page 58). With the use of (1.10), it was proved in Kyprianou and Palau (2017), that in the subcritical and critical cases the process has extinction a.s. In this paper, we want to find the asymptotic behaviour in the supercritical case.

The following Theorem 1.3 gives a relationship between the $L^1$-convergence of the martingale $\{W_t, t \geq 0\}$ and the following condition:

$$\sum_{i \in E} \int_{1 \leq |z| < \infty} \langle 1, z \rangle \ln(\langle 1, z \rangle) \mu_i(dz) < \infty. \quad (x \log x \text{ condition})$$

If $\mu_i(dz) = \pi_i(d\rho)$, where $z = \rho \pi$ with $\Pi_i$ being a measure on $(0, \infty)$ and $\pi$ a fixed probability mass function on the type space $E$ in vector form, the following theorem comes from Theorem 5.1 and Theorem 6.2 in Ren et al. (2016). See also Kyprianou and Palau (2017, Theorem 6).

**Theorem 1.3.** Suppose that $\lambda_1 > 0$. The following assertions hold:

1. If $(x \log x \text{ condition})$ holds, then for any $\mathbb{P}_x$, $W_\infty$ is the $L^1(\mathbb{P}_x)$ limit of $W_t$ as $t \to \infty$.

2. If $(x \log x \text{ condition})$ doesn’t hold, then for any $x \in \mathbb{R}^d_+$, $W_\infty = 0$, $\mathbb{P}_x$ a.s.

We will prove this theorem in Section 2. By using this theorem we obtain a strong law of large numbers for MCSBPs. This result matches perfectly classical analogues for multi-type Galton-Watson processes; see for example Theorem V.6.1 of Athreya and Ney (2004).

**Theorem 1.4.** Suppose that $X$ is a MCSBP with principal eigenvalue $\lambda_1 > 0$ and right and left associated eigenvectors $\phi, \hat{\phi} \in \mathbb{R}^d_+$. Then for any $x \in \mathbb{R}^d_+$,

$$\lim_{t \to \infty} e^{-\lambda_1 t} X_t = W_\infty \hat{\phi}, \quad \mathbb{P}_x \text{ a.s.}$$

As a corollary we obtain the following convergence on rates of types.

**Theorem 1.5.** For any $x \in \mathbb{R}^d_+ \setminus \{0\}$ we have, conditional on non-extinction,

$$\lim_{t \to \infty} \frac{X_t}{\langle 1, X_t \rangle} = \frac{\hat{\phi}}{\langle 1, \hat{\phi} \rangle}, \quad \mathbb{P}_x \text{ a.s.}$$
The remainder of this paper is structured as follows. In Section 2 we prove Theorem 1. The proof of Theorem 2 is given in Section 3.

2. Spine decomposition

A now classical way to prove Theorem 2 is to find a spine decomposition for \( \{X_t, t \geq 0\} \) under the Doob \( h \)-transform associated with \( W \). More precisely, for any \( x \in \mathbb{R}_+^d \), using the martingale \( (W_t, t \geq 0) \) we define a new probability measure via

\[
\frac{d\tilde{P}_x}{dP_x} = \frac{1}{\langle \phi, x \rangle} W_t, \quad t \geq 0.
\]

Where \( \{\mathcal{F}_t, t \geq 0\} \) is the natural filtration generated by \( X \).

Let \( (\eta_t, t \geq 0) \) be a Markov chain on \( E \) with infinitesimal generator \( L \), a \( d \times d \) matrix defined by

\[
L_{ij} = \frac{1}{\phi(i)} (B_{ij}^T - 1_{i=j} \lambda_1) \phi(j), \quad i,j \in E.
\]

Denote by \( \{P^\phi_i, i \in E\} \) the probabilities of \( \eta \) such that \( P^\phi_i(\eta_0 = i) = 1 \) for all \( i \in E \).

**Theorem 2.1.** If \( X \) is a MCSBP, then for any \( x \in \mathbb{R}_+^d \) and \( f \in \mathbb{R}_+^d \),

\[
\mathbb{E}_x \left[ e^{-\langle f, X_t \rangle} \right] = \mathbb{E}_x \left[ e^{-\langle f, X_t \rangle} \right] 
\]

\[
E^\phi_{\phi x} \left[ \exp \left\{ -\int_0^t \left( 2c(\eta_s)v_{\eta_s}(t-s,f) + \int_{\mathbb{R}_+^d} z(\eta_s)(1 - e^{-\langle v(t-s),z \rangle}) \mu(dz) \right) ds \right\} \right] \times \prod_{s \leq t} A_{\eta_s-\eta_s}^t,
\]

where the matrices \( \{A^s : s \geq 0\} \) are given by

\[
A_{ij}^t = \left( 1_{i \neq j} \right) \frac{1}{B_{ij}^T} \int_{\mathbb{R}_+^d} z(j)(e^{-\langle v(t-s),z \rangle} - 1) \mu_t(dz) + 1, \quad i,j \in E,
\]

and

\[
P^\phi_{\phi x} (\cdot) = \sum_{i \in E} \frac{\phi(i) x(i)}{\langle \phi, x \rangle} P^\phi_i (\cdot)
\]

with associated expectation operator \( E^\phi_{\phi x} (\cdot) \).

**Proof:** We start by noting that

\[
\mathbb{E}_x \left[ e^{-\langle f, X_t \rangle} \right] = e^{-\lambda t} \langle \phi, x \rangle \mathbb{E}_x \left[ \langle \phi, X_t \rangle e^{-\langle f, X_t \rangle} \right].
\]

Replacing \( f \) by \( f + \lambda \phi \) in (1.1) and (1.2) and differentiating with respect to \( \lambda \) and then setting \( \lambda = 0 \), we obtain

\[
\begin{align*}
\mathbb{E}_x \left[ e^{-\langle f, X_t \rangle} \right] &= \mathbb{E}_x \left[ e^{-\langle f, X_t \rangle} \right] \sum_{i \in E} \frac{\phi(i) x(i)}{\langle \phi, x \rangle} \theta(i) \nonumber \\\\\\\\nonumber \\
&= \mathbb{E}_x \left[ e^{-\langle f, X_t \rangle} \right] \frac{\theta(i \circ \phi \circ x)}{\langle \phi, x \rangle}, \quad \text{(2.1)}
\end{align*}
\]
where \( \odot \) denotes element wise multiplication of vectors and, for \( t \geq 0 \), \( \theta^t \) is the vector with entries
\[
\theta^t(i) := \frac{1}{\phi(i)} e^{-\lambda_i t} \frac{\partial}{\partial \lambda} \nu_i(t, f + \lambda \phi) \bigg|_{\lambda=0}.
\]

By an integration by parts, using \((1.2)\) and \((1.4)\) and that \((B \eta_i)_{j} = B^T \eta_i \), we get that \( \theta^t(i) \) is also the unique vector solution to
\[
\theta^t(i) = 1 + \int_0^t \frac{1}{\phi(i)} [(B^T - \lambda_i I)(\phi \odot \theta^s)](i) ds - \int_0^t \theta^s(i) 2c(i)v_i(s, f) ds
\]
\[
+ \int_0^t \int_{\mathbb{R}_+^d} \langle \psi^s, \phi \odot z \rangle (e^{-v(s, f, z)} - 1) \mu_i(dz) ds.
\]

Recall the definition of \( L \) and note that it conforms to the definition of an intensity matrix of a Markov chain, thanks to the fact that \( \phi \) is an eigenvector of \( B^T \). A (vectorial) integration by parts in the spirit of Theorem 3.1.2 of Dynkin (2002),
\[
[\theta^t](i) = [e^{tL}1](i) - \int_0^t e^{(t-s)L}[\theta^s(\cdot) \odot (2c(\cdot)v(\cdot, f))] (i) ds
\]
\[
+ \int_0^t e^{(t-s)L} \left[ \int_{\mathbb{R}_+^d} \langle \psi^s, \phi \odot z \rangle (e^{-v(s, f, z)} - 1) \frac{\mu_i(dz)}{\phi(\cdot)} \right] (i) ds,
\]
where \( 1 = (1, \ldots, 1)^T \in \mathbb{R}_+^d \). Then appealing to the fact that \( \{e^{tL} : t \geq 0\} \) is the semigroup of \( (\eta_i, P^\phi_t), i \in E \),
\[
\theta^t(i) = E^\phi_t[1] - \int_0^t E^\phi_t \left[ 2\theta^{t-s}(\eta_{t-s}) c(\eta_{t-s}) v_{\eta_{t-s}}(s, f) \right] ds
\]
\[
+ \int_0^t E^\phi_t \left[ \int_{\mathbb{R}_+^d} \langle \psi^{t-s}, \phi \odot z \rangle (e^{-v(s, f, z)} - 1) \frac{\mu_{\eta_{t-s}}(dz)}{\phi(\eta_{t-s})} \right] ds. \quad (2.2)
\]
Next, we make a change of variable \( u = t - s \) and separate the last inner product into two parts.
For all \( s \leq t \) and \( z \in \mathbb{R}_+^d \),
\[
\langle \psi^{t-s}, \phi \odot z \rangle = \theta^{t-s}(\eta_s) \phi(\eta_s) z(\eta_s) + \sum_{j \neq \eta_s} \theta^{t-s}(j) \phi(j) z(j).
\]
Therefore, \((2.2)\) is transformed into
\[
\theta^t(i) = E^\phi_t[g(\eta_t)] - \int_0^t E^\phi_t \left[ 2\theta^{t-s}(\eta_{t-s}) c(\eta_{t-s}) v_{\eta_{t-s}}(t - s, f) \right] ds
\]
\[
+ \int_0^t E^\phi_t \left[ \theta^{t-s}(\eta_s) \int_{\mathbb{R}_+^d} z(\eta_s)(e^{-v(t-s, f, z)} - 1) \mu_{\eta_s}(dz) \right] ds
\]
\[
+ \int_0^t E^\phi_t \left[ \sum_{j \neq \eta_s} \theta^{t-s}(j) \frac{\phi(j)}{\phi(\eta_s)} \int_{\mathbb{R}_+^d} z(j)(e^{-v(t-s, f, z)} - 1) \mu_{\eta_s}(dz) \right] ds.
\]
1.5

Chen et al. suggest that the process \( \{ X_t \mid t \geq 0 \} \) is henceforth denoted by \( P \) such that \( X \)ing to \( P \{ \text{immigrant} \} \)

\[
\mu_t(dz) = \int_{\mathbb{R}_+^d} z(i) \left( 1 - e^{-\langle v(s,f), z \rangle} \right) \mu_i (dz) + 1 ,
\]

we obtain

\[
\theta(t)(i) = E^\phi_t \left[ \exp \left\{ - \int_0^t \left( 2 c(\eta_s) v_{\eta_s}(t-s,f) + \int_{\mathbb{R}_+^d} z(\eta_s) \left( 1 - e^{-\langle v(t-s,f), z \rangle} \right) \mu_{\eta_s} (dz) \right) ds \right\} \prod_{s \leq t} A_{\eta_s} \right].
\]

Theorem 2.1 suggests that the process \((X_t, \tilde{P}_x)\) is equal in law to a process \( \{ \Gamma_t : t \geq 0 \} \), whose law is henceforth denoted by \( P_x, x \in \mathbb{R}_+^d \), where

\[
\Gamma_t = X_t + \sum_{s \leq t : c} X_{c,s}^{t-s} + \sum_{s \leq t : d} X_{d,s}^{t-s} + \sum_{s \leq t : j} X_{j,s}^{t-s}, \quad t \geq 0,
\]
such that \( X' \) is an independent copy of \((X_t, \tilde{P}_x)\) and the processes \( X^{c,s} \), \( X^{d,s} \) and \( X^{j,s} \) are defined through a process of immigration as follows: Given the path of the Markov chain \((\eta, P^\phi_x)\).

**Continuous immigration** in a Poissonian way a \( \psi \)-MCSBP \( X^{c,s}_t \) immigrates at \((s, \eta_s)\) with rate \( ds x 2c(\eta_s)dN_{\eta_s} \).

**Discontinuous immigration** in a Poissonian way a \( \psi \)-MCSBP \( X^{d,s}_t \) immigrates at \((s, \eta_s)\) with rate \( ds x \int_{\mathbb{R}_+^d} z(\eta_s) \mu_{\eta_s} (dz) \tilde{P}_x \).

**Jump immigration** at each jump time \( s \) of \( \eta \), a \( \psi \)-MCSBP \( X^{j,s}_t \) immigrates at \((s, \eta_s)\) with law \( \int_{\mathbb{R}_+^d} \nu_{\eta_{s- \eta_s}} (dz) \tilde{P}_x \) for each \( i, j \in E \),

\[
\nu_{i,j}(dz) = 1_{\langle i \neq j \rangle} \frac{1}{B_{ij}^t} z(j) \mu_i (dz) + \left( 1 - 1_{\langle i \neq j \rangle} \frac{1}{B_{ij}^t} \int_{\mathbb{R}_+^d} v(j) \mu_i (dv) \right) \delta_0 (dz).
\]

Given \( \eta \), the above three immigration processes are independent.

In the above description, the quantity \( N_t \) is the excursion measure of the \( \psi \)-MCSBP corresponding to \( P_{\eta_t} \). To be more precise, Dynkin and Kuznetsov (2004) showed that associated to the laws \( \{ P_{\eta_t} : t \in E \} \) are the measures \( \{ N_t : t \in E \} \), defined on the same measurable space, which satisfy

\[
N_t(1 - e^{-\langle f, X_t \rangle}) = - \log E_{\eta_t}(e^{-\langle f, X_t \rangle}),
\]

for all \( t \geq 0 \). A particular feature of \( N_t \) that we shall use later is that

\[
N_t(\langle f, X_t \rangle) = E_{\eta_t}(\langle f, X_t \rangle).
\]

Observe that the processes \( X^c, X^d \) and \( X^j \) are initially zero valued, therefore, if \( \Gamma_0 = x \) then \( X^c_0 = x \). The following result corresponds to a classical spine decomposition, albeit now for the
setting of an MCSBP. Note, we henceforth refer to the process \( \eta \) as the spine. By following the same proof as Theorem 5 in Kyprianou and Palau (2017) we can easily establish the next result.

**Theorem 2.2** (Spine decomposition). For any \( x \in \mathbb{R}_+^d \), \( (\Gamma_t, t \geq 0; \mathbb{P}_x) \) is equal in law to \( (X_t, t \geq 0; \mathbb{P}_x) \).

For the sake of brevity, we leave the proof to the reader.

### 2.1. Proof of Theorem 1.3

We follow a well established line of reasoning. We know that \( 1/W_t \) is a positive \( \mathbb{P}_x \)-supermartingale and hence \( \lim_{t \to \infty} W_t \) exists \( \mathbb{P}_x \)-almost surely. Therefore \( W_t \) converges in \( L^1(\mathbb{P}_x) \) to a non-degenerated limit as soon as we prove that \( \mathbb{P}_x(\liminf_{t \to \infty} W_t < \infty) = 1 \).

We consider the spine decomposition in Theorem 2.2. Given the spine \( \eta \), let us write \( (s, I^d_s, I^4_s)_{s \geq 0} \) for the process of immigrated vector along the spine (i.e. \( I^d_s = X^{d,s}_0 \) and \( I^4_s = X^{4,s}_0 \)). Then \( (s, I^d_s) \) is Poissonian with intensity \( ds \times z(\eta_s)\mu_{\eta_s}(dz) \) and, if \( s \) is such that \( \eta_s \neq \eta \) then \( I^d_s \) is distributed according to \( \nu_{\eta_s - \eta} \). Let \( S = \sigma(\eta_s, (s, I^d_s, I^4_s), s \geq 0) \) be the sigma algebra which informs the location of the spine and the vector issued at each immigration time and write

\[
Z_t := e^{-\lambda_1 t} \langle \phi, \Gamma_t \rangle.
\]

Since \( (\Gamma_t, \mathbb{P}_x) \) is equal in law to \( (X_t, \mathbb{P}_x) \), to prove \( \mathbb{P}_x(\liminf_{t \to \infty} W_t < \infty) = 1 \), we only need to prove that

\[
\mathbb{P}_x(\liminf_{t \to \infty} Z_t < \infty) = 1. \tag{2.4}
\]

By Fatou’s Lemma

\[
\mathbb{E}_x[\liminf_{t \to \infty} Z_t|S] \leq \liminf_{t \to \infty} \mathbb{E}_x[Z_t|S].
\]

It therefore remains to show that \( \liminf_{t \to \infty} \mathbb{E}_x[Z_t|S] < \infty, \mathbb{P}_x \) a.s.

By using that the processes \( X^{c,s}, X^{d,s} \) conditioned on \( S \) are Poissonian, the description of \( X^{s}, I^1 \) and \( I^4 \), formula (2.3) and that \( W \) is a martingale, we have that for \( t \geq 0 \) and \( x \in \mathbb{R}_+^d \),

\[
\liminf_{t \to \infty} \mathbb{E}_x[Z_t|S] = \langle \phi, x \rangle + \int_0^\infty 2c(\eta_s)e^{-\lambda_1 s} \phi(\eta_s)ds + \sum_{0 \leq s} e^{-\lambda_1 s} \langle \phi, I^d_s \rangle + \sum_{0 \leq s} e^{-\lambda_1 s} \langle \phi, I^4_s \rangle.
\]

Since \( \lambda_1 > 0 \), the first integral is finite. We need to prove that the other sums are finite a.s. In order to do it, we will decompose the sum in small jumps: \( \{(s, I^d_s) : \langle 1, I^d_s \rangle \leq e^{\lambda_1 s}\} \) and big jumps: \( \{(s, I^d_s) : \langle 1, I^d_s \rangle > e^{\lambda_1 s}\} \), and we handle \( I^d_s \) in similar way. Denote \( M_\phi := \max\{\phi(i) : i \in E\} \). For the small jumps, by the definition of \( \nu \),

\[
\mathbb{E}_x \left[ \sum_{0 \leq s} e^{-\lambda_1 s} \langle \phi, I^d_s \rangle \mathbb{1}_{\{\langle 1, I^d_s \rangle \leq e^{\lambda_1 s}\}} + \sum_{0 \leq s} e^{-\lambda_1 s} \langle \phi, I^4_s \rangle \mathbb{1}_{\{\langle 1, I^4_s \rangle \leq e^{\lambda_1 s}\}} \right] \\
= \mathbb{E}_x \left[ \int_0^\infty \int_{\{1, z\} \leq e^{\lambda_1 s}} e^{-\lambda_1 s} z(\eta_s)\phi(z)\mu_{\eta_s}(dz)ds + \int_0^\infty \int_{\{1, z\} \leq e^{\lambda_1 s}} e^{-\lambda_1 s} \phi(z)\nu_{\eta_s - \eta_s}(dz)ds \right] \\
\leq CM_\phi \sum_{i \in E} \int_0^\infty \int_{\{1, z\} \leq e^{\lambda_1 s}} e^{-\lambda_1 s} \langle 1, z \rangle^2 \mu_i(dz)ds,
\]

where \( C \) is a positive constant. For each \( i \in E \),

\[
\int_0^\infty \int_{\{1, z\} \leq e^{\lambda_1 s}} e^{-\lambda_1 s} \langle 1, z \rangle^2 \mu_i(dz)ds \leq \int_{\{1, z\} \leq 1} \langle 1, z \rangle^2 \mu_i(dz) + \int_{\{1, z\} > 1} \langle 1, z \rangle \mu_i(dz) < \infty.
\]
Therefore,
\[
\sum_{0 \leq s} e^{-\lambda_1 s} \langle \phi, I^d_s \rangle 1_{\{1, I^d_s \leq e^{\lambda_1 s}\}} + \sum_{0 \leq s} e^{-\lambda_1 s} \langle \phi, I^i_s \rangle 1_{\{1, I^i_s \leq e^{\lambda_1 s}\}} < \infty, \quad P_x \text{ a.s.}
\]

For the big jumps, using Fubini’s Theorem, we get
\[
E_x \left[ \sum_{0 \leq s} 1_{\{1, I^d_s \leq e^{\lambda_1 s}\}} + \sum_{0 \leq s} 1_{\{1, I^i_s \leq e^{\lambda_1 s}\}} \right] = E_x \left[ \int_0^\infty \left( \int_{(1, z)} > e^{\lambda_1 s} \right) \mu_i (d\zeta) \right] = C \sum_{i \in E} \int_{(1, z)} > e^{\lambda_1 s} \ln \langle (1, z) \rangle \mu_i (d\zeta) < \infty.
\]
This implies that $P_x$ a.s. we have finitely many big jumps and therefore
\[
\sum_{0 \leq s} e^{-\lambda_1 s} \langle \phi, I^d_s \rangle 1_{\{1, I^d_s \leq e^{\lambda_1 s}\}} + \sum_{0 \leq s} e^{-\lambda_1 s} \langle \phi, I^i_s \rangle 1_{\{1, I^i_s \leq e^{\lambda_1 s}\}} < \infty, \quad P_x \text{ a.s.}
\]

So, $\lim \inf_{t \to \infty} E_x[Z_t|S] < \infty, P_x \text{ a.s.}$

Now, we will prove the second part of the Theorem. Since
\[
\widetilde{P}_x(\lim \sup_{t \to \infty} W_t = \infty) = P_x(\lim \sup_{t \to \infty} Z_t = \infty),
\]
if we prove that
\[
\lim \sup_{t \to \infty} Z_t = \infty \quad P_x \text{ a.s.} \quad (2.5)
\]
then $\widetilde{P}_x$ and $P_x$ are singular and hence
\[
P_x(\lim \sup_{t \to \infty} W_t = 0) = 1.
\]

It remains to show (2.5). Suppose that for a fixed $i \in E$,
\[
\int_{(1, z) > 1} (1, z) \ln \langle (1, z) \rangle \mu_i (d\zeta) = \infty.
\]

We will divide the proof in two parts.

(i) First assume that
\[
\int_{(1, z) > 1} z(i) \ln \langle (1, z) \rangle \mu_i (d\zeta) = \infty.
\]

Denote by $T$ the set of times at which we immigrate $(s, X^{d,s})$ along the spine, then for $s \in T$,
\[
Z_s \geq e^{-\lambda_1 s} \langle \phi, X^{d,s}_0 \rangle.
\]

To prove (2.5), we only need to prove that
\[
\lim \sup_{T \geq s \to \infty} e^{-\lambda_1 s} \langle \phi, X^{d,s}_0 \rangle = \infty.
\]
Since \( e^{-\lambda s} \langle \phi, X_t^{d,s} \rangle \geq m\phi e^{-\lambda s} \langle 1, X_0^{d,s} \rangle \), where \( m\phi := \min \{ \phi(i) : i \in E \} \), we only need to prove that
\[
\limsup_{T \to s \to \infty} e^{-\lambda s} \langle 1, X_0^{d,s} \rangle = \infty. \tag{2.6}
\]

For \( T, K > 1 \), define the subsets
\[
A_{T,K} := \{ s \in T \cap (T, \infty) : \langle 1, X_0^{d,s} \rangle > K e^{\lambda s} \}.
\]

Then, given the Markov chain \( (\eta, P^\phi) \), \( A_{T,K} \) is a Poisson random variable with parameter \( \int_T^\infty \int_{\langle 1, z \rangle > K e^{\lambda s}} z(\eta) \mu_{\eta}(dz) ds \). To prove (2.6), we only need to prove that
\[
\int_T^\infty \int_{\langle 1, z \rangle > K e^{\lambda s}} z(\eta) \mu_{\eta}(dz) ds = \infty, \quad P^\phi_{\phi x} \text{ a.s.}
\]
for all \( T, K > 1 \). Observe that \( \eta \) is ergodic. Then there exists \( C_i > 0 \) and random \( S \) such that
\[
\int_0^t 1_{\{\eta_s = i\}} ds \geq C_i t \quad \text{for all } t \geq S \quad P^\phi_{\phi x} \text{ a.s.}
\]
Let us denote by \( R = \max \{ Ke^{\lambda T}, Ke^{\lambda S} \} \). Then, by Fubini’s Theorem and the previous inequality,
\[
\int_T^\infty \int_{\langle 1, z \rangle > K e^{\lambda s}} z(\eta) \mu_{\eta}(dz) ds \geq \int_T^\infty \int_{\langle 1, z \rangle > K e^{\lambda s}} z(\eta) 1_{\{\eta_s = i\}} \mu_{\eta}(dz) ds \\
\geq \frac{C_i}{\lambda} \int_{\langle 1, z \rangle > R} z(i) \ln((1, z)) \mu_i(dz) - D = \infty,
\]
where \( D = (\lambda^{-1} \ln(K) + T) \int_{\langle 1, z \rangle > R} z(i) \mu_i(dz) < \infty \). Therefore we have (2.5).

(ii) Next suppose that, for \( j \neq i \),
\[
\int_{\langle 1, z \rangle > 1} z(j) \ln((1, z)) \mu_i(dz) = \infty.
\]
By inequality (1.5) and the ergodicity of \( \eta \), the set \( \tau := \{ s \geq 0 : \eta_s = i, \eta_s = j \} \) is not bounded. For all \( s \in T \)
\[
Z_s \geq e^{-\lambda s} \langle \phi, X_0^{d,s} \rangle
\]
Let us denote by \( \tau_1, \tau_2, \ldots \) a enumeration of these times in increasing order. By applying the distribution of \( X_t^{d,j} \) in the jump times \( \tau_n \) we have that for all \( K > 0, \)
\[
\sum_{n \geq 1} P_x \{ e^{-\lambda \tau_n} \langle 1, X_0^{d,\tau_n} \rangle \geq K \} = \sum_{n \geq 1} E_x \left[ P_x \{ e^{-\lambda \tau_n} \langle 1, X_0^{d,\tau_n} \rangle \geq K \mid \tau_n \} \right] \\
= \frac{1}{B_{ij}} \sum_{n \geq 1} E_x \left[ \int_{\mathbb{R}_+^d} 1_{\{ e^{-\lambda \tau_n} \langle 1, z \rangle \geq K \}} z(j) \mu_i(dz) \right] \\
= \frac{1}{B_{ij}} E_x \left[ \sum_{n \geq 1} \int_{\mathbb{R}_+^d} 1_{\{ e^{-\lambda \tau_n} \langle 1, z \rangle \geq K \}} z(j) \mu_i(dz) \right]
\]
By renewal theory, there exist \( A \in (0, \infty) \) and a subset \( \Omega_1 \) with \( P_x(\Omega_1) = 1 \) such that for all \( \omega \in \Omega_1 \) there exists \( N = N(\omega) > 0 \) such that
\[
\tau_n \leq An, \quad \text{for all } n \geq N.
\]
Then,
\[
\sum_{n \geq 1} \int_{\mathbb{R}^d_+} 1_{\{e^{-\lambda_1 \tau_n (1, z)} \geq K\}} z(j) \mu_i(dz) \geq \sum_{n \geq N} \int_{\mathbb{R}^d_+} 1_{\{e^{-\lambda_1 A_n (1, z)} \geq K\}} z(j) \mu_i(dz).
\]
By the integral test criterion for series, the previous series is divergent since
\[
\int_{N}^{\infty} \int_{\mathbb{R}^d_+} 1_{\{e^{-\lambda_1 A_s (1, z)} \geq K\}} z(j) \mu_i(dz) ds = \frac{1}{A \lambda_1} \int_{(1, z) > K} z(j) \ln(\langle 1, z \rangle) \mu_i(dz) - D = \infty,
\]
where \(D = ((\lambda_1 A)^{-1} \ln(K) + N) \int_{(1, z) > K} z(i) \mu_i(dz) < \infty\). This implies
\[
\sum_{n \geq 1} P_X(e^{-\lambda_1 \tau_n (1, X_{0}^{j, \tau_n})} \geq K) = E_X \left[ \sum_{n \geq 1} \int_{\mathbb{R}^d_+} 1_{\{e^{-\lambda_1 \tau_n (1, z)} \geq K\}} z(j) \mu_i(dz) \right] = \infty.
\]
Therefore, by the Borel Cantelli Lemma,
\[
\limsup_{n \to \infty} e^{-\lambda_1 \tau_n (1, X_{0}^{j, \tau_n})} \geq K, \quad P_X \text{ a.s.}
\]
for any \(K > 0\), and then
\[
\limsup_{n \to \infty} e^{-\lambda_1 \tau_n (1, X_{0}^{j, \tau_n})} = \infty.
\]
Hence we have
\[
\limsup_{s \to \infty} Z_s \geq \limsup_{n \to \infty} e^{-\lambda_1 \tau_n (\phi, X_{0}^{j, \tau_n})} = \infty,
\]
which says that (2.5) holds. \(\square\)

3. Proof of Theorem 1.4

Suppose that \((x \log x \text{ condition})\) doesn’t hold, then
\[
\limsup_{t \to \infty} e^{-\lambda_1 t} X_t(i) \leq \lim_{t \to \infty} \frac{1}{\phi(t)} e^{-\lambda_1 t} \langle \phi, X_t \rangle = 0 \quad P_{\xi} \text{ a.s.}
\]
We therefore focus on the case when \((x \log x \text{ condition})\) holds. In order to do this, we will separate small jumps from big jumps in the Poisson measures. More precisely, for each \(i \in E\), let us define the Poisson random measures
\[
N_i^{(1)}(ds, dz, dr) := 1_{\{1, z) \leq e^{\lambda_1 t}\}} N_i(ds, dz, dr)
\]
and
\[
N_i^{(2)}(ds, dz, dr) := 1_{\{1, z) > e^{\lambda_1 t}\}} N_i(ds, dz, dr)
\]
and denote by \(\tilde{N}_i^{(1)}\) and \(\tilde{N}_i^{(2)}\) their compensated versions, respectively.
We are going to compute the proof of Theorem 1.4 in three steps. First, in lattice times, we will approximate the value of the limit by the value of the limit of a conditional expectation. With this relation, we are going to find our limit in lattice times. And finally in the third step, we will extend the result to continuous times.
3.1. **Proof for lattice times.** First, we will prove Theorem 1.4 in lattice times. For each $\delta > 0$, consider the lattice times $n\delta$, $n \in \mathbb{N}$. We will approximate the value of the limit by the value of the limit of a conditional expectation.

**Lemma 3.1.** If (\textit{x log x condition}) holds, then for any $m \in \mathbb{N}$, $\sigma > 0$ and $x \in \mathbb{R}_+^d$,

$$\lim_{n \to \infty} e^{-\lambda_1(n+m)\sigma} X_{(n+m)\sigma} - \mathbb{E}_x \left[ e^{-\lambda_1(n+m)\sigma} X_{(n+m)\sigma} \mid \mathcal{F}_{n\sigma} \right] = 0, \quad \text{in } L^1(\mathbb{P}_x) \text{ and } \mathbb{P}_x \text{ a.s.}$$

**Proof:** The result is true if we prove that for all $k \in E$,

$$\lim_{n \to \infty} e^{-\lambda_1(n+m)\sigma} \langle e_k, X_{(n+m)\sigma} \rangle - \mathbb{E}_x \left[ e^{-\lambda_1(n+m)\sigma} \langle e_k, X_{(n+m)\sigma} \rangle \mid \mathcal{F}_{n\sigma} \right] = 0, \quad \text{in } L^1(\mathbb{P}_x) \text{ and } \mathbb{P}_x \text{ a.s.}$$

Let $s, t \geq 0$. By the Markov property we have

$$e^{-\lambda_1(t+s)} \langle e_k, X_{t+s} \rangle - \mathbb{E}_x \left[ e^{-\lambda_1(t+s)} \langle e_k, X_{t+s} \rangle \mid \mathcal{F}_t \right] = e^{-\lambda_1(t+s)} \langle e_k, X_{t+s} \rangle - e^{-\lambda_1(t+s)} \langle M(s) e_k, X_t \rangle.$$

Now, applying equation (1.8) to the times $t$ and $t+s$, we obtain

$$e^{-\lambda_1(t+s)} \langle e_k, X_{t+s} \rangle - e^{-\lambda_1(t+s)} \langle M(s) e_k, X_t \rangle = \sum_{i \in E} e^{-\lambda_1(t+s)} \int_t^{t+s} [M(t + s - u) e_k]_i \sqrt{2c_i X_{u,i}} dW_{u,i}$$

$$+ \sum_{i \in E} e^{-\lambda_1(t+s)} \int_t^{t+s} \int_{\mathbb{R}_+} \int_0^\infty \langle M(t + s - u) e_k, z \rangle 1_{\{t \leq X_{u,i} \}} \tilde{N}_i(du, dz, dr)$$

$$= C_{t,t+s}(e_k) + S_{t,t+s}(e_k) + B_{t,t+s}(e_k), \quad (3.1)$$

where

$$C_{t,t+s}(e_k) := \sum_{i \in E} e^{-\lambda_1(t+s)} \int_t^{t+s} [M(t + s - u) e_k]_i \sqrt{2c_i X_{u,i}} dW_{u,i},$$

$$S_{t,t+s}(e_k) := \sum_{i \in E} e^{-\lambda_1(t+s)} \int_t^{t+s} \int_{\mathbb{R}_+} \int_0^\infty \langle M(t + s - u) e_k, z \rangle 1_{\{t \leq X_{u,i} \}} \tilde{N}_i(du, dz, dr),$$

$$B_{t,t+s}(e_k) := \sum_{i \in E} e^{-\lambda_1(t+s)} \int_t^{t+s} \int_{\mathbb{R}_+} \int_0^\infty \langle M(t + s - u) e_k, z \rangle 1_{\{t \leq X_{u,i} \}} \tilde{N}_i(2)(du, dz, dr).$$

To complete the proof, we need to control the convergence of the above three terms.

(i) **Lattice convergence of $C_{t,t+s}(e_k)$:** We will show that for any $k \in E$, $m \in \mathbb{N}$, $\sigma > 0$ and $x \in \mathbb{R}_+^d$

$$\lim_{n \to \infty} C_{\sigma \infty(n+m)\sigma}(e_k) = 0, \quad \text{in } L^2(\mathbb{P}_x) \text{ and } \mathbb{P}_x \text{ a.s.}$$

First note that for $t \in [n\sigma, (n + m)\sigma]$, the process

$$C_{t}^{(n,m,\sigma)} := \sum_{i \in E} e^{-\lambda_1(n+m)\sigma} \int_{n\sigma}^t \langle M((n + m)\sigma - u) e_k \rangle_i \sqrt{2c_i X_{u,i}} dW_{u,i} \quad (3.2)$$

is a continuous local martingale with quadratic variation given by

$$\sum_{i \in E} e^{-2\lambda_1(n+m)\sigma} \int_{n\sigma}^t \langle [M((n + m)\sigma - u) e_k]_i \rangle^2 2c_i X_{u,i} du.$$
Then, by taking \( t = (n + m)\sigma \), we have

\[
\mathbb{E}_x \left[ \left( C_{n\sigma,(n+m)\sigma}(e_k) \right)^2 \right] = e^{-2\lambda_1(n+m)\sigma} \mathbb{E}_x \left[ \sum_{i \in E} \int_{n\sigma}^{(n+m)\sigma} \left( [M((n+m)\sigma - u)e_k]_i \right)^2 c_i X_{u,i} du \right].
\]

Denote by \( C = \max\{ \epsilon_i : i \in E \} \). Observe that \( (M(t)e_k)_i = M(t)_{i,k} \) and by equation (1.9) exists \( C_1 > 0 \) such that \( \|M(t)\| \leq C_1 e^{\lambda_1 t} \). Recall that \( m_{\phi} = \min\{ \phi(i) : i \in E \} \). Then

\[
\mathbb{E}_x \left[ \left( C_{n\sigma,(n+m)\sigma}(e_k) \right)^2 \right] \leq \frac{2CC_1^2}{m_{\phi}} e^{-2\lambda_1(n+m)\sigma} \mathbb{E}_x \left[ \int_{n\sigma}^{(n+m)\sigma} e^{2\lambda_1[(n+m)\sigma - u]} \langle \phi, X_u \rangle du \right]
\]

\[
= \frac{2CC_1^2 \langle \phi, x \rangle}{\lambda_1 m_{\phi}} [e^{-\lambda_1 n\sigma} - e^{-\lambda_1(n+m)\sigma}]
\]

\[
= \frac{2CC_1^2 \langle \phi, x \rangle}{\lambda_1 m_{\phi}} [1 - e^{-\lambda_1 m\sigma}] e^{-\lambda_1 n\sigma},
\]

where in the first equality we used the fact that \( W_u = e^{-\lambda_1 u} \langle \phi, X_u \rangle \) is a martingale. Therefore

\[
\sum_{n=1}^{\infty} \mathbb{E}_x \left[ \left( C_{n\sigma,(n+m)\sigma}(e_k) \right)^2 \right] < \infty. \quad (3.3)
\]

Then we have the \( \mathbb{L}^2(\mathbb{P}_x) \)-convergence. The \( \mathbb{P}_x \) a.s. convergence follows from Chebyshev’s inequality, Borel-Cantelli Lemma and the previous inequality.

(ii) Lattice convergence of \( S_{t,\epsilon} e_k \): We will show that, if \( (x \log x \text{ condition}) \) holds, then for any \( k \in E, \ m \in \mathbb{N}, \sigma > 0 \) and \( x \in \mathbb{R}_+^d \),

\[
\lim_{n \to \infty} S_{n\sigma,(n+m)\sigma}(e_k) = 0, \quad \text{in} \ \mathbb{L}^2(\mathbb{P}_x) \ \text{and} \ \mathbb{P}_x \ a.s.
\]

Similar to the proof in (i) above, for \( t \in [n\sigma, (n+m)\sigma] \), the process,

\[
S_{t,(n+m,\sigma)} := e^{-\lambda_1(n+m)\sigma} \sum_{i \in E} \int_{n\sigma}^{t} \int_{\mathbb{R}_+^d} \int_{0}^{\infty} \langle M((n+m)\sigma - u)e_k, z \rangle \mathbb{1}_{\{r \leq X_{u,i} \}} d\mu_i(\{z \}) \ d\mu_i(\{u \}) \ dr du
\]

is a martingale with quadratic variation given by

\[
e^{-2\lambda_1(n+m)\sigma} \sum_{i \in E} \int_{n\sigma}^{t} \int_{\mathbb{R}_+^d} \int_{0}^{\infty} \langle M((n+m)\sigma - u)e_k, z \rangle^2 \mathbb{1}_{\{r \leq X_{u,i} \}} d\mu_i(\{z \}) \ d\mu_i(\{u \}) \ dr du.
\]

Then, by taking \( t = (n + m)\sigma \), we have

\[
\mathbb{E}_x \left[ \left( S_{n\sigma,(n+m)\sigma}(e_k) \right)^2 \right] = e^{-2\lambda_1(n+m)\sigma} \sum_{i \in E} \mathbb{E}_x \left[ \int_{n\sigma}^{(n+m)\sigma} \langle M((n+m)\sigma - u)e_k, z \rangle^2 X_{u,i} \mathbb{1}_{\{z \leq e^{\lambda_1 r} \}} d\mu_i(\{z \}) \ dr du \right].
\]

By equation (1.9), there exists \( C > 0 \) such that for all \( t \geq 0 \),

\[
\langle M(t)e_k, z \rangle \leq Ce^{\lambda_1 t}\mathbb{1}(z).
\]

(3.5)
Therefore, by using the definition of $m_\phi$

$$E_x \left[ \left( S_{n\sigma,(n+m)\sigma}(e_k) \right)^2 \right]$$

$$\leq \frac{C^2}{m_\phi} \sum_{i \in E} E_x \left[ \int_{n\sigma}^{(n+m)\sigma} \int_{\mathbb{R}_+^d} e^{-2\lambda_1 u} \langle 1, z \rangle^2 \langle \phi, X_u \rangle \mathbf{1}_{\{\langle z, \sigma \rangle \leq e^{\lambda_1 u}\}} \mu_i(dz) du \right]$$

$$= \frac{C^2}{m_\phi} \sum_{i \in E} \int_{\mathbb{R}_+^d} e^{-\lambda_1 u} \langle 1, z \rangle^2 \langle \phi, X_u \rangle \mathbf{1}_{\{\langle z, \sigma \rangle \leq e^{\lambda_1 u}\}} \mu_i(dz) du,$$

where in the first equality we used the fact that $W_u = e^{-\lambda_1 u} \langle \phi, X_u \rangle$ is a martingale. Taking sum over $n$, we get

$$\sum_{n=1}^{\infty} E_x \left[ \left( S_{n\sigma,(n+m)\sigma}(e_k) \right)^2 \right] \leq \frac{C^2}{m_\phi} \sum_{n=1}^{\infty} \sum_{i \in E} \int_{\mathbb{R}_+^d} e^{-\lambda_1 u} \langle 1, z \rangle^2 \langle \phi, X_u \rangle \mathbf{1}_{\{\langle z, \sigma \rangle \leq e^{\lambda_1 u}\}} \mu_i(dz) du.$$

By Fubini’s Theorem applied to the Lebesgue measure in $\mathbb{R}$ and the countable measure in $\mathbb{N}$, we get

$$\sum_{n=1}^{\infty} E_x \left[ \left( S_{n\sigma,(n+m)\sigma}(e_k) \right)^2 \right] \leq \frac{C^2}{m_\phi} \sum_{i \in E} \int_{\mathbb{R}_+^d} \int_{0}^{\infty} e^{-\lambda_1 u} \langle 1, z \rangle^2 \langle \phi, X_u \rangle \mathbf{1}_{\{\langle z, \sigma \rangle \leq e^{\lambda_1 u}\}} \mu_i(dz) du.$$

By Fubini’s Theorem, for each $i \in E$,

$$\int_{0}^{\infty} \int_{\mathbb{R}_+^d} e^{-\lambda_1 u} \langle 1, z \rangle^2 \mathbf{1}_{\{\langle z, \sigma \rangle \leq e^{\lambda_1 u}\}} \mu_i(dz) du$$

$$\leq \int_{\{z \leq 1\}} 0 \int_{\mathbb{R}_+^d} e^{-\lambda_1 u} \langle 1, z \rangle^2 \mu_i(dz) du + \int_{\{z > 1\}} 0 \int_{\mathbb{R}_+^d} e^{-\lambda_1 u} \langle 1, z \rangle^2 \mu_i(dz) du$$

$$= \frac{1}{\lambda_1} \left( \int_{\{z \leq 1\}} \langle 1, z \rangle^2 \mu_i(dz) + \int_{\{z > 1\}} \langle 1, z \rangle (\ln(\langle z, \sigma \rangle \rangle + 1) \mu_i(dz) \right) < \infty.$$

Since $(x \log x)$ condition holds,

$$\sum_{n=1}^{\infty} E_x \left[ \left( S_{n\sigma,(n+m)\sigma}(e_k) \right)^2 \right] < \infty \quad (3.6)$$

and we have the convergence in $L^2(\mathbb{P}_x)$. By Chebyshev’s inequality and Borel-Cantelli Lemma we have the $\mathbb{P}_x$ a.s. convergence.

(iii) Lattice convergence of $B_{t+t^\phi}(e_k)$: We show that if $(x \log x)$ condition holds, then for any $k \in E, \ m \in \mathbb{N}, \ \sigma > 0$ and $x \in \mathbb{R}_+^d$,

$$\lim_{n \to \infty} B_{n\sigma,(n+m)\sigma}(e_k) = 0, \quad \text{in } L^1(\mathbb{P}_x) \text{ and } \mathbb{P}_x \text{ a.s.}$$

Note that for any random measure $N$, we have $\hat{N}(A) \leq N(A) + \hat{N}(A)$, where $\hat{N}$ is the compensated measure and $\hat{N}$ the intensity measure. Then, by inequality (3.5)
Using the fact that 

\[
\int_D^\infty e^{-\lambda u} \chi_{\{r \leq X_{u,i}\}} \chi_{\{1, z\}} (\{1, z\} > e^{\lambda u}) \mu_i (dz) du \
\]  

(3.7)

By Fubini’s Theorem,

\[
\mathbb{E}_x \left[ |B_{n,m}(n+m)\sigma (e_k)| \right] \leq \frac{2C}{m_\phi} \sum_{i \in E} \mathbb{E}_x \left[ \int_{n\sigma}^\infty \int_{x^+}^\infty e^{-\lambda u} \chi_{\{1, z\}} (\{1, z\} > e^{\lambda u}) \mu_i (dz) du \right] 
\]

Recall that \( \int_{1/n, z < \infty} \chi_{\{1, z\}} (\{1, z\} > e^{\lambda u}) \mu_i (dz) < \infty \). Therefore

\[
\lim_{n \to \infty} \mathbb{E}_x \left[ |B_{n,m}(n+m)\sigma (e_k)| \right] = 0, 
\]

which says \( \lim_{n \to \infty} B_{n,m}(n+m)\sigma (e_k) = 0 \) in \( L^1 (\mathbb{P}_x) \). The \( \mathbb{P}_x \) a.s. convergence follows from the fact that

\[
n \mapsto \int_{n\sigma}^\infty \int_{x^+}^\infty e^{-\lambda u} \chi_{\{1, z\}} (\{1, z\} > e^{\lambda u}) \mu_i (dz) du 
\]

is decreasing and inequality (3.7).

Now applying (i)-(iii) to (3.1), the proof is complete. \( \square \)

**Proposition 3.2.** If \( (x \log x \text{ condition}) \) holds, then for any \( \sigma > 0 \),

\[
\lim_{n \to \infty} e^{-\lambda_1 n\sigma} X_{n\sigma} = W_\infty \hat{\phi}, \quad \text{in} \ L^1 (\mathbb{P}_x) \text{ and} \ \mathbb{P}_x \text{ a.s.}
\]

**Proof:** Let \( k \in E \) and \( n, m > 0 \). By the Markov property, we have

\[
\mathbb{E}_x \left[ e^{-\lambda_1 (n+m)\sigma} \{e_k, X_{(n+m)\sigma}\} \right| F_{n\sigma} \right] = e^{-\lambda_1 (n+m)\sigma} \{M(m\sigma)e_k, X_{n\sigma}\}.
\]

(3.8)

Let

\[
r_m = \left( 1 - \frac{c_1 e^{-c_2 m\sigma}}{\max \{ \phi(i) \hat{\phi}(k) : i, k \in E \} } \right) \quad \text{and} \quad R_m = \left( 1 + \frac{c_1 e^{-c_2 m\sigma}}{\min \{ \phi(i) \hat{\phi}(k) : i, k \in E \} } \right).
\]

Observe that \( r_m \to 1 \) and \( R_m \to 1 \) as \( m \to \infty \). Moreover, by limit (1.9), for all \( i \in E \)

\[
r_m \phi(i) \hat{\phi}(k) \leq e^{-\lambda_1 m\sigma} \{M(m\sigma)e_k\} = e^{-\lambda_1 m\sigma} M(m\sigma)_{ik} \leq R_m \phi(i) \hat{\phi}(k).
\]

Hence,

\[
r_m \hat{\phi}(k) e^{-\lambda_1 n\sigma} \{\phi, X_{n\sigma}\} \leq e^{-\lambda_1 (n+m)\sigma} \{M(m\sigma)e_k, X_{n\sigma}\} \leq R_m \hat{\phi}(k) e^{-\lambda_1 n\sigma} \{\phi, X_{n\sigma}\}.
\]
Now, applying Lemma 3.1, the previous equation and equation (3.8), we get
\[
\lim_{n \to \infty} e^{-\lambda_1 n \sigma} X_{n \sigma}(k) = \lim_{n \to \infty} \lim_{m \to \infty} \sup_{n \to \infty} e^{-\lambda_1 (n+m) \sigma} (e_k, X_{(n+m)\sigma})
\]
\[
= \lim_{n \to \infty} \lim_{m \to \infty} e^{-\lambda_1 (n+m) \sigma} (M(m \sigma)e_k, X_{n \sigma})
\]
\[
\leq \lim_{n \to \infty} \lim_{m \to \infty} R_m \phi(k) W_{n \sigma}
\]
\[
= \hat{\phi}(k) W_\infty, \quad \mathbb{P}_x \text{ a.s.}
\]
In a similar way,
\[
\lim_{n \to \infty} e^{-\lambda_1 n \sigma} X_{n \sigma}(k) = \hat{\phi}(k) W_\infty, \quad \mathbb{P}_x \text{ a.s.}
\]
Therefore, the a.s. assertion is true. Recall that \(m_\phi := \min\{\phi(k), k \in E\} > 0\). Observe that \(0 \leq e^{-\lambda_1 n \sigma} X_{n \sigma}(k) \leq W_{n \sigma} m_\phi^{-1}\) and by Theorem 1.3 the martingale \(W_t\) converges in \(L^1(\mathbb{P}_x)\). Then by the Generalized Dominated Convergence Theorem, the \(L^1(\mathbb{P}_x)\) assertion holds. (see for instance Dudley (2002, Problem 12, p. 133)), \(\Box\)

3.2. From lattice times to continuous times. In this section, we extend the convergence along lattice times in Theorem 1.4 to convergence along continuous times and conclude our main results.

Proof of Theorem 1.4: Since \(\phi\) is a positive vector, then for any \(a \in \mathbb{R}^d\) we have \(|\langle a, X_t \rangle| \leq \frac{\|a\|}{m_\phi} \langle \phi, X_t \rangle\), where \(m_\phi := \min\{\phi(i) : i \in E\}\). Therefore \(\mathbb{P}_x\) a.s.
\[
\lim_{\sigma \to 0} \lim_{n \to \infty} \sup_{t \in [n \sigma, (n+1) \sigma]} |e^{-\lambda_1 t} \langle M((n+1) \sigma - t)e_k, X_t \rangle - e^{-\lambda_1 t} \langle e_k, X_t \rangle|
\]
\[
\leq \lim_{\sigma \to 0} \lim_{n \to \infty} \sup_{t \in [n \sigma, (n+1) \sigma]} e^{-\lambda_1 t} \langle \phi, X_t \rangle \frac{\|M((n+1) \sigma - t)e_k - e_k\|}{m_\phi}
\]
\[
\leq \left( \lim_{\sigma \to 0} \lim_{n \to \infty} \sup_{t \in [n \sigma, (n+1) \sigma]} W_t \right) \left( \lim_{\sigma \to 0} \sup_{u \in [0, \sigma]} \frac{\|M(u)e_k - e_k\|}{m_\phi} \right) = 0.
\]
So, in order to have our result, it is enough to prove that
\[
\lim_{\sigma \to 0} \lim_{n \to \infty} \sup_{t \in [n \sigma, (n+1) \sigma]} e^{-\lambda_1 t} \langle M((n+1) \sigma - t)e_k, X_t \rangle = \hat{\phi}(k) W_\infty, \quad \mathbb{P}_x \text{ a.s.}
\]
By applying equation (1.7) to \(e_k\) and \(n \sigma \leq t \leq (n+1) \sigma\), we obtain
\[
e^{-\lambda_1 t} \langle M((n+1) \sigma - t)e_k, X_t \rangle
\]
\[
e^{-\lambda_1 t} \langle M(\sigma)e_k, X_{n \sigma} \rangle
\]
\[
+ e^{-\lambda_1 t} \sum_{i \in E} \int_{n \sigma}^{t} \int_{X_{u,i}}^{\infty} (M((n+1) \sigma - u)e_k) \sqrt{2c_i X_{u,i}} dW_{u,i}
\]
\[
+ e^{-\lambda_1 t} \sum_{i \in E} \int_{n \sigma}^{t} \int_{\mathbb{R}_+} \int_{0}^{\infty} (M((n+1) \sigma - u)e_k, x) 1_{\{u \leq X_{u,i}\}} \tilde{N}_i^{(1)}(du, dz, dl)
\]
\[
+ e^{-\lambda_1 t} \sum_{i \in E} \int_{n \sigma}^{t} \int_{\mathbb{R}_+} \int_{0}^{\infty} (M((n+1) \sigma - u)e_k, x) 1_{\{u \leq X_{u,i}\}} \tilde{N}_i^{(2)}(du, dz, dl)
\]
\[
= e^{-\lambda_1 t} \langle M(\sigma)e_k, X_{n \sigma} \rangle + C_{n,t}^{\sigma}(e_k) + S_{n,t}^{\sigma}(e_k) + B_{n,t}^{\sigma}(e_k).
\] (3.9)
By the result for lattice times (Proposition 3.2), $P_x$ a.s.
\[
\lim_{\sigma \to 0} \lim_{n \to \infty} \sup_{t \in [n\sigma,(n+1)\sigma]} e^{-\lambda t}\langle M(\sigma)e_k, X_{n\sigma} \rangle = \lim_{\sigma \to 0} \lim_{n \to \infty} e^{-\lambda \sigma n}\langle M(\sigma)e_k, X_{n\sigma} \rangle = \hat{\phi}(k)W_\infty.
\]
Hence, to complete the proof, we only need to prove that the last three terms on the right-hand side of (3.9) converge uniformly for $t \in [n\sigma, (n+1)\sigma]$ first as $n \to \infty$ and then $\sigma \to 0$.

(i) Convergence of $C_{n,t}^\sigma(e_k)$: We show that for any $k \in E$ and $x \in \mathbb{R}_+$,
\[
\lim_{\sigma \to 0} \lim_{n \to \infty} \sup_{t \in [n\sigma,(n+1)\sigma]} C_{n,t}^\sigma(e_k) = 0 \quad P_x \text{ a.s.}
\]
Recall the definition of the martingale $C_t^{(n,1,\sigma)}$ given by (3.2). And note that
\[
|C_{n,t}^\sigma(e_k)| \leq e^{\lambda \sigma}|C_t^{(n,1,\sigma)}|
\]
Then, by the maximal inequality for martingales, for all $\epsilon > 0$ we have that for
\[
P_x \left( \sup_{t \in [n\sigma,(n+1)\sigma]} |C_{n,t}^\sigma(e_k)| > \epsilon \right) \leq P_x \left( \sup_{t \in [n\sigma,(n+1)\sigma]} e^{\lambda \sigma}|C_t^{(n,1,\sigma)}| > \epsilon \right) \leq \frac{e^{2\lambda \sigma}}{\epsilon^2}P_x \left[ |C_{(n+1)\sigma}^{(n,1,\sigma)}|^2 \right]
\]
Note that $c_{(n+1)\sigma}^{(n,1,\sigma)} = C_{n\sigma,(n+1)\sigma}(e_k)$, therefore by (3.3),
\[
\sum_{n=1}^{\infty} P_x \left( \sup_{t \in [n\sigma,(n+1)\sigma]} |C_{n,t}^\sigma(e_k)| > \epsilon \right) < \infty.
\]
By Borel-Cantelli we have the result.

(ii) Convergence of $S_{n,t}^\sigma(e_k)$: We show that, if $(x \log x \text{ condition})$ holds, then for any $k \in E$ and $x \in \mathbb{R}_+$,
\[
\lim_{\sigma \to 0} \lim_{n \to \infty} \sup_{t \in [n\sigma,(n+1)\sigma]} S_{n,t}^\sigma(e_k) = 0 \quad P_x \text{ a.s.}
\]
The proof is analogous to the previous one. But this time we use the martingale $S_t^{(n,1,\sigma)}$ given by (3.4) and equation (3.6).

(iii) Convergence of $B_{n,t}^\sigma(e_k)$: We show that, if $(x \log x \text{ condition})$ holds, then for any $k \in E$ and $x \in \mathbb{R}_+$,
\[
\lim_{\sigma \to 0} \lim_{n \to \infty} \sup_{t \in [n\sigma,(n+1)\sigma]} B_{n,t}^\sigma(e_k) = 0 \quad P_x \text{ a.s.}
\]
By inequality (3.5),
\[
|B_{n,t}^\sigma(e_k)| \leq Ce^{-\lambda \sigma (t-(n+1)\sigma)} \sum_{i \in E} \int_{n\sigma}^{n\sigma + t} \int_0^\infty e^{-\lambda u}(1,z)1_{\{r \leq X_{n\sigma}\}}1_{\{(1,z) > e^{\lambda \sigma u}\}}(dN_i + d\mu_i(dz)du)
\]
\[
\leq Ce^{-\lambda \sigma (t-(n+1)\sigma)} \sum_{i \in E} \int_0^{\infty} \int_{n\sigma}^{n\sigma + t} \int_0^\infty e^{-\lambda u}(1,z)1_{\{r \leq X_{n\sigma}\}}1_{\{(1,z) > e^{\lambda \sigma u}\}}(dN_i + d\mu_i(dz)du).
\]
Then,
\[
\sup_{t \in \left[ n\sigma, (n+1)\sigma \right]} |B_{n,t}^\sigma(e_k)| \\
\leq C e^{\lambda_1 \sigma} \sum_{i \in E} \int_{n\sigma}^\infty \int_{\mathbb{R}_+^d} \int_{0}^\infty e^{-\lambda u} \langle 1, z \rangle 1_{\{r \leq X_{u,i}\}} \{\langle 1, z \rangle > e^{\lambda_1 u}\} (dN_i + dr\mu_i(dz)du).
\]

The claim is true by following the same steps after equation (3.7). We omit the details here.

Putting the above three conclusions together, we now conclude
\[
\lim_{t \to \infty} e^{-\lambda t} (e_k, X_t) = \hat{\phi}(k) W_\infty, \quad \mathbb{P}_x \text{ a.s.}
\]
as required. \qed
