Aims. During the first wave of coronavirus pandemic, many Psychiatry outpatient appointments moved rapidly to remote or ‘virtual’ to protect patients and staff from infection. Telephone consultations do not allow assessment of appearance or other visual aspects of behaviour/afflict, yet these are core components of Mental State Examination. Videoconsultation software was unfamiliar to many mental health clinicians, with obstacles including hardware availability, software provision and skills, data security as well as lack of clinician motivation and confidence preventing rapid uptake. I wanted to take advantage of excellent IT support, and NHS England funding of software licence, to drive introduction of Attend Anywhere patient videoconsultation (‘telepsychiatry’) software within my local ADAPT (Anxiety, Depression and Personality Disorder, Trauma) Community Mental Health Team from April 2020 onwards.

Method. I assembled a small group of clinicians to take part in a local pilot of Attend Anywhere software. One Care Coordinator, a Consultant Psychologist, two Consultant Psychiatrists and myself completed satisfaction and confidence scores throughout an 8 week period. Number of videoconsultation outpatient appointments offered to and accepted by patients were also recorded. Weekly group meetings were deemed impossible to schedule given pandemic workloads, so we used 1:1 quick remote catchups, identifying and troubleshooting obstacles, working with IT implement a work-around when the team hit a technical brick wall.

Result. Clinician confidence and satisfaction increased significantly during this period, as did number of offered & completed video consultations. Attend Anywhere consultations were used for up to 25% of clinician weekly workload.

Clinicians who manage their own diaries started quickly

It was difficult to successfully engage Administration team to organise Attend Anywhere test calls, leading to slow uptake for Consultant Psychiatrists who do not manage their own diaries.

Conclusion. Patient obstacles to use of Attend Anywhere appeared to be idiosyncratic and multifactorial, including poverty, digital exclusion, lack of privacy at home, and clinical history of online grooming. However, some patients already used Attend Anywhere software with their physical health teams, while others prefer video call to phone. Age was not an obstacle.

Once this small group of clinicians began to use software successfully, it had a snowball effect within the team and other clinicians asked to sign up for the service. Full support from Administration teams will be crucial to increasing video calls within the service. Clinicians suggested offering video consultation as an opt-out service and requested additional functionality from the software to widen use.

Improving physical health for psychiatric patients detained in a low secure forensic psychiatric unit in the United Kingdom

Cosmina Cross
Southern Health NHS Trust
doi: 10.1192/bjo.2021.490

Aims. This project aimed to improve physical health and to tackle obesity in patients detained in a low secure forensic psychiatric unit.

Background. People suffering from severe and enduring mental health problems have a life expectancy of 15-20 years less than the general population. The main cause of death is cardiovascular disease due to lifestyle factors, such as smoking, substance misuse and obesity.

Physical health problems such as metabolic syndrome, diabetes and heart disease have a knock on effect on motivation, self-esteem and concordance with treatment.

Bowel monitoring in psychiatry of old age: a quality improvement project

doi: 10.1192/bjo.2021.489

Aims. This project aims to ensure all patients in the dementia ward 1 in Kingsway Care Centre, Dundee have daily bowel monitoring and achieve a normal bowel habit. The hypothesis is that patients are inadequately screened and substantial undiagnosed constipations exist.

Background. Constipation has a prevalence of 16-50% among individuals over 65 years old in the community. Psychiatric illnesses are known risk factors with older psychiatric patients 3-6 times more likely to be constipated. Untreated constipation may progress to serious complications such as bowel obstruction and bowel perforation. Delirium, often mislabelled as worsening psychiatric symptoms, also may occur leading to additional psychotropic medications being prescribed, further worsening the constipation.

Method. All patients in Ward 1, Kingsway Care Centre Dundee over 4 months were included, amounting to 25 patients. Data were gathered from stool charts weekly. Quality improvement framework was followed with two plan-do-study-act (PDSA) cycles completed. Normal bowel function was assessed against ROME IV constipation criteria and less than 75% of Bristol stool type 6 or 7 due to the risk of overflow diarrhoea and laxative overuse. In the first PDSA cycle, stool charts were modified to account for patients independently mobilising to the bathroom and daily documentation even if bowel movements were uncertain. The second PDSA cycle introduced a sticker on charts folder to “ask the patient” along with a staff education leaflet on the complications of constipation. Data were anonymised and analysed with run charts using Microsoft Excel.

Result. At baselines, 50% of patients had a stool chart. This increased to 90% in cycle 1, 100% in cycle 2. 28% of patients had any stools documented at baselines. This increased to 31% in cycle 1, 59% in cycle 2. At baselines, 0% of patients had a normal bowel habit. This maintained at 0% in cycle 1 but increased to 13% in cycle 2. No serious complications were found in patients assisted with toileting. However, 34% of independently mobile patients developed serious complications.

Conclusion. Poor documentation existed in all patients, particularly those independently mobile. Independently mobile patients were particularly at risk of serious complications of constipation compared to assisted patients. Introduction of new stool charts in the first PDSA cycle resulted in increased documentation but limited benefit for identification of constipation. The second PDSA cycle, targeting staff education and compliance, showed an increase in identification of constipation indicating limited staff knowledge as a key barrier to improvement in patients’ bowel habit.
Method. Baseline data were collected using Body Mass Index (BMI) and Simple Physical Activity Questionnaire (SPAQ). Following the initial data collection, patients were involved in focus groups, community meetings and a monthly physical health action group. There was input from the care team including psychology, occupational therapy, nursing, catering and security. New activities have been made available such as “physical health and mental health education group”, “rambling group”, “gym sessions”, “patient focus groups” and “walking group”.

Result. This project has been running for 9 months and is ongoing. There has been a modest change in the BMI – initial results ranging from BMI 23.6–42.8kg/m². Of the initial cohort (n = 14), there has been weight loss (n = 3), weight gain (n = 3) and no change (n = 8).

The initial SPAQ results showed that on average patients spend 19.8 hours per day either in bed or doing sedentary activities and only 1.68 hours per day walking or doing physical activities. This pattern is being reassessed.

The qualitative data from patient focus groups shows increased interest in activities, motivation and desire to contribute to the project. Conclusion. The preliminary results show an increase in patient motivation and engagement with available activities. There have also been patient-led challenges which were well received. Patients feel positive about the programme and valued for their input. Further support is required to maintain progress.

Assessing the practice of written referrals to neuroradiology and how this process can be improved and standardised

Fraser Currie1*, Rashi Negi2 and Hari Shammugaramnam2

doi: 10.1192/bjo.2021.492

Aims. This quality improvement project aims to improve the quality of information provided in the referrals from the older adult psychiatry department to radiology when requesting neuroradiological imaging.

The secondary outcome aims to standardise information on the referral proforma. We hypothesise that this improved referral proforma will lead to improved quality of reporting from the radiology department, which will form the second stage of this quality improvement project.

A further area of interest of this exercise is to establish whether standardised radiological scoring systems are requested in the referral, as these can be utilised as a means to standardise reported information.

Method. Retrospective electronic case analysis was performed on 50 consecutive radiology referrals for a period of 3 months from November 2019 to January 2020. Data were obtained from generic MRI and CT referral proforma and entered into a specifically designed data collection tool. Recorded were patient demographics, provisional diagnosis, modality of imaging, use of ACE-III cognitive score, radiological scoring systems, and inclusion and exclusion criteria.

Result. Results from 50 referrals have shown: 60% were male, 40% female. Average patient age of 74, ranging from 49 to 95. 58% were referred for CT head with 42% for MRI head. More than half of referrals quoted the ACE-III score. 26% of referrals stated exclusion criteria such as space occupying lesions, haemorrhages or infarcts. 10% of referrals requested specific neuro-radiological scoring scales. Specific scales which were requested included GCA (global cortical atrophy), MTA scale (medial temporal atrophy), Koedam scale (evidence of parietal atrophy) and Fazekas (evidence of vascular changes). Only 80% of referrals included the patients GP details on the referral form.
