(Dated: Ngày 26 tháng 11 năm 2014)

Following our approach to the electroweak phase transition (EWPT) in our previous work [1], we consider the EWPT in the economical 3-3-1 (E331) model. Our analysis shows that the EWPT in the model is a sequence of two first-order phase transitions, $SU(3) \rightarrow SU(2)$ at the TeV scale and $SU(2) \rightarrow U(1)$ at the 100 GeV scale. The EWPT $SU(3) \rightarrow SU(2)$ is triggered by the new bosons and the exotic quarks; its strength is about $1 - 13$ if the mass ranges of these new particles are $10^2 \text{GeV} - 10^3 \text{GeV}$. The EWPT $SU(2) \rightarrow SU(1)$ is strengthened by only the new bosons; its strength is about $1 - 1.15$ if the mass parts of $H_1^0$, $H_2^+$ and $Y^+$ are in the ranges $10 \text{GeV} - 10^2 \text{GeV}$. The contributions of $H_1^0$ and $H_2^+$ to the strengths of both EWPTs may make them sufficiently strong to provide large deviations from thermal equilibrium and B violation necessary for baryogenesis.

I. INTRODUCTION

In the context of electroweak baryogenesis (EWBG), the EWPT plays an important role in explaining the Baryon Asymmetry of Universe (BAU) by electroweak physics. From the three Sakharov conditions, which are B violation, C and CP violations, and deviation from thermal equilibrium \[2\], the EWPT should be a strongly first-order phase transition. That not only leads to thermal imbalance \[3\], but also makes a connection between B violation and CP violation via nonequilibrium physics \[4\].

The EWPT has been investigated in the Standard Model (SM) \[3, 5\] as well as various extension models \[6–14\]. For the SM, although the EWPT strength is larger than unity at the electroweak scale, it is still too weak for the mass of the Higgs boson to be compatible with current experimental limits \[3, 5\]; this suggests that EWBG requires new physics beyond the SM at the weak scale \[6\]. Many extensions such as the Two-Higgs-Doublet model or Minimal Supersymmetric Standard Model have a more strongly first-order phase transition and the new sources of CP violation, which are necessary to account for the BAU; triggers for the first-order phase transition in these models are heavy bosons or dark matter candidates \[10–12, 14\].

Among the extensions beyond the SM, the models based on $SU(3)_C \otimes SU(3)_L \otimes U(1)_X$ gauge group (called 3-3-1 for short) \[16, 18\] have some interesting features including the ability to explain the generation problem \[16, 18\] and the electric charge quantization \[19\]. The structure of such a gauge group requires the 3-3-1 models to have at least two Higgs triplets. Thus the structure of symmetry breaking and the number of bosons are different from those in the SM.

In a previous work \[1\], we have considered the EWPT in the reduced minimal 3-3-1 (RM331) model due to its simplicity, and found that our approach can be applied to the more complicated 3-3-1 models. In the present work, we follow the same approach for the economical 3-3-1 (E331) model \[20\], whose lepton sector is more complicated than that of the RM331 model. The E331 model has the right-handed neutrino in the leptonic content, the bileptons (two singly charged gauge bosons $W^{\pm}$, $Y^{\pm}$, and a neutral gauge boson $X^0$),
the heavy neutral boson $Z_2$, and the exotic quarks. The model has two Higgs triplets, and
the physical scalar spectrum is composed of a singly charged scalar $H_2^\pm$ and a neutral scalars
$H_1^0$ [20]. We will show in this paper that the new bosons and the exotic quarks can be triggers
for the first-order phase transition in the model.

This paper is organized as follows. In Sec. II we give a review of the E331 model on
the Higgs, gauge boson, and lepton sectors. In Sec. III we find the effective potential in
the model, which has a contribution from heavy bosons and exotic quarks as well as a
contribution similar to that in the SM. In Sec. IV we investigate the structure of the EWPT
sequence in the E331 model, find the parameter ranges where the EWPTs are the strongly
first-order to provide B violation necessary for baryogenesis, and show the constraints on
the mass of the charged Higgs boson. Finally, we summarize and describe outlooks in Sec.
V.

II. A REVIEW OF THE ECONOMICAL 331 MODEL

A. Higgs potential

In the E331 model, the 3-3-1 gauge group is spontaneously broken via two stages. In the
first stage, the group $SU(3)_L \otimes U(1)_X$ breaks down to the $SU(2)_L \otimes U(1)_Y$ of the SM; and
the second stage takes place as that we have known in the SM. This sequence of spontaneous
symmetry breaking (SSB) is described by the Higgs potential [20]:

$$V(\chi, \phi) = \mu_1^2 \chi^\dagger \chi + \mu_2^2 \phi^\dagger \phi + \lambda_1 (\chi^\dagger \chi)^2 + \lambda_2 (\phi^\dagger \phi)^2 +$$
$$+ \lambda_3 (\chi^\dagger \phi) (\phi^\dagger \phi) + \lambda_4 (\chi^\dagger \chi) (\phi^\dagger \phi),$$

in which $\chi$ and $\phi$ are the Higgs scalar triplets:

$$\chi = \begin{pmatrix} \chi_1^0 \\ \chi_2^- \\ \chi_3^0 \end{pmatrix} \sim \begin{pmatrix} 1 \\ 3 \\ -1/3 \end{pmatrix}, \quad \phi = \begin{pmatrix} \phi_1^+ \\ \phi_2^0 \\ \phi_3^+ \end{pmatrix} \sim \begin{pmatrix} 1 \\ 3 \\ -1/3 \end{pmatrix},$$

whose VEVs are respectively given by:

$$\langle \chi \rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} u \\ 0 \\ \omega \end{pmatrix}, \quad \langle \phi \rangle = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 \\ v \end{pmatrix},$$

(2)
where the VEV \( \omega \) is responsible for the first stage, and the VEVs \( u \) and \( v \) are responsible for the second stage of symmetry breaking. These VEVs satisfy the constraint \([20]\):

\[
\omega \gg v \gg u.
\]  

(4)

The physical scalar spectrum of the model is composed of a charged scalar \( H^+_2 \), and two neutral scalars \( H^0_1 \) and \( H^0 \). In this spectrum, \( H^0 \) is both the lightest neutral field and a \( SU(2)_L \) component, hence it is identified as the SM Higgs boson. The Higgs content of the model can be summarized as follows:

\[
\chi = \begin{pmatrix}
\frac{1}{\sqrt{2}} u + G_{X^0} \\
G_{Y^-}
\end{pmatrix}, \quad
\phi = \begin{pmatrix}
G_{W^+} \\
\frac{1}{\sqrt{2}} (v + H^0 + iG_Z) \\
H^+_2
\end{pmatrix},
\]  

(5)

where the Higgs masses are given by:

\[
m^2_{H^0} = \lambda_2 v^2 + \lambda_1 (u^2 + \omega^2) - \sqrt{[\lambda_2 v^2 - \lambda_1 (u^2 + \omega^2)]^2 + \lambda_3^2 v^2 (u^2 + \omega^2)} \\
\approx \frac{4\lambda_1 \lambda_2 - \lambda_3^2}{2\lambda_1} v^2, \quad (6)
\]

\[
m^2_{H^0_1} = \lambda_2 v^2 + \lambda_1 (u^2 + \omega^2) + \sqrt{[\lambda_2 v^2 - \lambda_1 (u^2 + \omega^2)]^2 + \lambda_3^2 v^2 (u^2 + \omega^2)} \\
\approx 2\lambda_1 \omega^2 + \frac{\lambda_3^2}{2\lambda_1} v^2, \quad (7)
\]

\[
m^2_{H^+_2} = \frac{\lambda_1}{2} (u^2 + v^2 + \omega^2). \quad (8)
\]

We note that in Ref. [20], the mass formula of \( H^0_1 \) is approximate as \( m^2_{H^0_1} \approx 2\lambda_1 \omega^2 \). In the context of EWPT, however, we find that the better approximation should be that in Eq. (7). Although the additional term \( \frac{\lambda_3^2}{2\lambda_1} v^2 \) is very small as compared to the first term and we may neglect it in some other considerations, it gives a very important contribution of \( H^0_1 \) to the EWPT \( SU(2) \to U(1) \).

**B. Gauge boson sector**

The masses of the gauge bosons of this model come from the Lagrangian

\[
\mathcal{L}^{GB}_{mass} = (\mathcal{D}_\mu \chi)\dagger (\mathcal{D}^\mu \chi) + (\mathcal{D}_\mu \phi)\dagger (\mathcal{D}^\mu \phi),
\]  

(9)

where

\[
\mathcal{D}_\mu = \partial_\mu - igT_i W_{i\mu} - igX T_9 X B_\mu,
\]  

(10)
with $T_g = \frac{1}{\sqrt{6}} \text{diag}(1, 1, 1)$ so that $\text{Tr}(T_i T_j) = \delta_{ij}$. The couplings of $SU(3)_L$ and $U(1)_X$ satisfy the relation:

$$t \equiv \frac{g_X}{g} = \frac{3\sqrt{2}s_W}{3 - 4s_W^2},$$

(11)

where $c_W = \cos \theta_W$, $s_W = \sin \theta_W$, $t_W = \tan \theta_W$, and $\theta_W$ is the Weinberg angle.

Eqs. (9) and (3) lead to:

$$W_{\mu}^{\prime \pm} = \frac{W_1 \mp iW_2}{\sqrt{2}}, \quad Y_{\mu}^{\prime \mp} = \frac{W_6 \mp iW_7}{\sqrt{2}},$$

(12)

$$m_W^2 = \frac{g^2 v^2}{4}, \quad m_Y^2 = \frac{g^2 (u^2 + v^2 + \omega^2)},$$

(13)

The combinations $W'$ and $Y'$ in (12) are mixed via a mass matrix:

$$L_{\text{mass}}^{CG} = \frac{g^2}{4} (W_{\mu}^{\prime -}, Y_{\mu}^{\prime -}) \begin{pmatrix} u^2 + v^2 & u\omega \\ u\omega & \omega^2 + v^2 \end{pmatrix} \begin{pmatrix} W_{\mu}^{\prime +} \\ Y_{\mu}^{\prime +} \end{pmatrix}.$$

(14)

Diagonalizing the mass matrix in Eq. (14), we acquire the physical charged gauge bosons

$$W_\mu = \cos \theta W_\mu' - \sin \theta Y_\mu', \quad Y_\mu = \sin \theta W_\mu' - \cos \theta Y_\mu',$$

(15)

and their respective mass eigenvalues

$$m_W^2 = \frac{g^2 v^2}{4}, \quad m_Y^2 = \frac{g^2 (u^2 + v^2 + \omega^2)},$$

(16)

where $\theta$ is the mixing angle which is defined by

$$t_\theta \equiv \tan \theta = \frac{u}{\omega}.$$

(17)

The mass $m_W$ as in (16) suggests that the $W$ bosons of the model can be identified as those of the SM, and $v$ can be set as $v \approx v_{\text{weak}} = 246 \text{ GeV}$. From the constraints in (14), $\theta$ should be very small, thus $W_\mu \simeq W_\mu'$ and $Y_\mu \simeq Y_\mu'$. Moreover, the Michel parameter $\rho$ in the model connects $u$ with $v$ by the expression $\rho \approx 1 + \frac{3u^2}{v^2}$ \cite{20}; and from the experimental data, $\rho = 0.9987 \pm 0.0016$ \cite{23}, that expression gives us $\frac{u}{v} \leq 0.01$, which leads to $u < 2.46 \text{ GeV}$. With $\omega$ in the range $1 \text{ TeV} - 5 \text{ TeV}$, we have

$$t_\theta = \frac{u}{\omega} \approx 0.001.$$

(18)
For the neutral gauge bosons, the mass matrix in the basis \((W_{3\mu}, W_{8\mu}, B_\mu, W_{4\mu})\) is given by

\[
M^2 = \frac{g^2}{4} \begin{pmatrix}
  u^2 + v^2 & \frac{u^2 - v^2}{\sqrt{3}} & -\frac{2t}{3\sqrt{6}}(u^2 + 2v^2) & 2u\omega \\
  \frac{u^2 - v^2}{\sqrt{3}} & \frac{1}{2}(4\omega^2 + u^2 + v^2) & \frac{\sqrt{2}}{9}(2\omega^2 - u^2 + 2v^2) & -\frac{2}{\sqrt{3}}u\omega \\
  -\frac{2t}{3\sqrt{6}}(u^2 + 2v^2) & \frac{2t}{9}(2\omega^2 - u^2 + 2v^2) & -\frac{2t}{27}(\omega^2 + u^2 + 4v^2) & -\frac{8t}{3\sqrt{6}}u\omega \\
  2u\omega & -\frac{2}{\sqrt{3}}u\omega & -\frac{8t}{3\sqrt{6}}u\omega & u^2 + \omega^2
\end{pmatrix}.
\] (19)

The diagonalization of the mass matrix in Eq. (19) leads to the mass eigenstates of four following neutral gauge bosons:

\[
m_{\gamma}^2 = 0, \quad m_{W_4}^2 = \frac{g^2}{4}(u^2 + \omega^2),
\]

(20)

\[
m_{Z_1}^2 = [2g^{-2}\sqrt{3 - 4s_W^2}]^{-1} \left\{ [c_W^2(u^2 + \omega^2) + v^2 \right.
\frac{-\sqrt{[c_W^2(u^2 + \omega^2) + v^2]^2 + (3 - 4s_W^2)(3u^2\omega^2 - u^2v^2 - v^2\omega^2)}}{3 - 4s_W^2}
\left. \right\},
\]

(21)

\[
m_{Z_2}^2 = [2g^{-2}\sqrt{3 - 4s_W^2}]^{-1} \left\{ [c_W^2(u^2 + \omega^2) + v^2 \right.
\frac{+\sqrt{[c_W^2(u^2 + \omega^2) + v^2]^2 + (3 - 4s_W^2)(3u^2\omega^2 - u^2v^2 - v^2\omega^2)}}{3 - 4s_W^2}
\left. \right\}.
\]

(22)

Due to the constraints (4), the physical states \(Z_1\) and \(Z_2\) get masses

\[
m_{Z_1}^2 = \frac{g^2}{4c_W^2}(v^2 - 3u^2), \quad m_{Z_2}^2 = \frac{g^2c_W^2\omega^2}{3 - 4s_W^2}.
\]

(23)

Since the components \(W_4'\) and \(W_5\) have the same mass, we can identify their combination,

\[
X_{\mu}^0 = \frac{1}{\sqrt{2}}(W_{4\mu} - iW_{5\mu}),
\]

(24)

as a physical neutral non-Hermitian gauge boson, which carries the lepton number with two units. The subscript 0 of \(X_\mu\) in Eq. (24) denotes neutrality of the gauge boson \(X\) but sometimes this subscript may be dropped.
C. Fermion sector

The fermion content in this model, which is anomaly free, is given by

\[
\psi_i^L = \begin{pmatrix} \nu_i \\ e_i \\ \chi_i^0 \end{pmatrix}_L \sim (1, 3, -1/3), \quad e_i^R \sim (1, 1, -1), \quad i = 1, 2, 3,
\]

\[
Q_{1L} = \begin{pmatrix} u_1 \\ d_1 \\ U \end{pmatrix}_L \sim (3, 3, 1/3), \quad Q_\alpha^L = \begin{pmatrix} d_\alpha \\ u_\alpha \\ D_\alpha \end{pmatrix}_L \sim (3, 3^*, 0), \quad \alpha = 2, 3,
\]

\[
u_i^L \sim (3, 1, 2/3), \quad d_i^R \sim (3, 1, -1/3), \quad u_R \sim (3, 1, 2/3), \quad D_{\alpha R} \sim (3, 1, -1/3). \tag{25}
\]

The Yukawa interactions which induce masses for the fermions can be written as

\[
\mathcal{L}_{\text{Yuk}} = \mathcal{L}_{\text{LNC}} + \mathcal{L}_{\text{LNV}} \tag{26}
\]

in which $\mathcal{L}_{\text{LNC}}$ is the Lagrangian part for lepton number conservation and $\mathcal{L}_{\text{LNV}}$ is that for lepton number violation. These Lagrangian parts are given by:

\[
\mathcal{L}_{\text{LNC}} = h^U_i \bar{Q}_{1L}^c \chi U_R + h^D_{\alpha \beta} \bar{Q}_\alpha^L \chi^* D_{\beta R} \\
+ h^{\epsilon \delta}_{ij} \bar{\psi}_{iL}^c \epsilon_j e_R + h^{\epsilon \delta \eta \zeta}_{iabc} (\bar{\psi}_{iL}^c)_a (\psi_{jL}^c)_b (\phi)_c \\
+ h_i^d \bar{Q}_{1L} \phi d^c_{iR} + h_u^{\alpha \beta} \bar{Q}_\alpha^L \phi^* u_{iR} + \text{H.c.}
\]

\[
\mathcal{L}_{\text{LNV}} = s_i^U \bar{Q}_{1L}^c \chi u_{iR} + s_\alpha^d \bar{Q}_\alpha^L \chi^* d_{iR} \\
+ s^D_i \bar{Q}_{1L} \phi D_{\alpha R} + s_\alpha^U \bar{Q}_\alpha^L \phi^* U_R + \text{H.c.} \tag{27}
\]

where $a$, $b$ and $c$ stand for the $SU(3)_L$ indices.

During the SSB sequence of this model, the VEV $\omega$ gives the masses for the exotic quarks $U$ and $D_\alpha$, the VEV $u$ which is the source of lepton-number violations gives the masses for the quarks $u_1$ and $d_\alpha$, the VEV $v$ gives the masses for the quarks $u_\alpha$ and $d_1$ as well as all ordinary leptons.
III. EFFECTIVE POTENTIAL IN THE ECONOMICAL 331 MODEL

From the Higgs potential (1), we obtain $V_0$ in a form which is dependent on the VEVs as follows:

$$V_0(u, \omega, v) = \frac{\mu_1^2}{2}(u^2 + \omega^2) + \frac{\mu_2^2}{2}v^2 + \frac{\lambda_1}{4}(u^4 + \omega^4 + 2u^2\omega^2) + \frac{\lambda_2}{4}v^4 + \frac{\lambda_3}{4}(u^2v^2 + v^2\omega^2). \quad (28)$$

We see that $V_0(u, \omega, v)$ has a quartic form like in the SM, but it depends on three variables, $u$, $\omega$ and $v$; it also has the mixings between these variables. However, we can transform $u$ into $\omega$ by $t_\theta$ as defined in Eq. (17). We note that, if the Universe’ energies allow of the existence of the gauge symmetry $SU(3)_L \otimes U(1)_X$ and the SSB sequence in the E331 model, the VEVs $u$, $\omega$ and $v$ must satisfy the constraint (4). This leads to $t_\theta \ll 1$, and we can neglect the contribution of $u$. On the other hand, by developing the Higgs potential (1), we obtain two minimum equations which permit us to transform the mixing between $\omega$ and $v$ to the form that depends only on $\omega$ or $v$.

Therefore, we can write $V_0$ in Eq. (28) as a sum of two parts corresponding to two stages of SSB:

$$V_0(\omega, v) = V_0(\omega) + V_0(v), \quad (29)$$

in which $V_0(\omega)$ and $V_0(v)$ are still in the quartic form.

In order to derive the effective potential, we start from the full Higgs Lagrangian:

$$\mathcal{L} = \mathcal{L}^{GB\text{mass}} + V(\chi, \phi), \quad (30)$$

where $\mathcal{L}^{GB\text{mass}}$ and $V(\chi, \phi)$ are respectively given by (9) and (1).

Expanding the Higgs fields $\chi$ and $\phi$ around their VEVs which are $u$, $\omega$ and $v$, we obtain

$$\mathcal{L} = \frac{1}{2}\partial^\mu \omega \partial_\mu \omega + \frac{1}{2}\partial^\mu v \partial_\mu v + V_0(\omega, v) + \sum_{\text{boson}} m_{\text{boson}}^2(\omega, v)W^\mu W_\mu. \quad (31)$$

where $W$ runs over all gauge fields and Higgs bosons. In the E331 model, we have two massive bosons like the SM bosons $Z_1$ and $W^\pm$, two new heavy neutral boson $X$ and $Z_2$, the singly charged gauge bosons $Y^\pm$, one singly charged Higgs $H^\pm_2$, one heavy neutral Higgs $H^0_1$ and one SM-like Higgs $H^0$. The masses of the gauge bosons and the Higgses presented in Table I from which we can split the boson masses into two parts for two SSB stages:

$$m_{\text{boson}}^2(\omega, v) = m_{\text{boson}}^2(\omega) + m_{\text{boson}}^2(v). \quad (32)$$
Bảng I. Mass formulations of bosons in the E331 model

| Bosons          | $m^2(\omega, v)$ | $m^2(\omega)$ | $m^2(v)$ |
|-----------------|------------------|---------------|----------|
| $m^2_{\omega \pm}$ | $\frac{g^2}{4} v^2$ | 0             | 80.39$^2$ (GeV)$^2$ |
| $m^2_{Y \pm}$    | $\frac{g^2}{4}(\omega^2 + v^2)$ | $\frac{g^2}{4} \omega^2$ | 80.39$^2$ (GeV)$^2$ |
| $m^2_{\chi^0}$   | $\frac{g^2}{4} \omega^2$ | $\frac{g^2}{4} \omega^2$ | 0        |
| $m^2_{Z_1} \sim m^2_{Z_2}$ | $\frac{g^2}{4} v^2$ | 0             | 91.68$^2$ (GeV)$^2$ |
| $m^2_{Z_2} \sim m^2_{Z'}$ | $\frac{g^2}{3-4s^2} v^2$ | $\frac{g^2}{3-4s^2} \omega^2$ | 0        |
| $m^2_{H^0}$      | $\frac{1}{2} (2\lambda_2 - \frac{\lambda_2^2}{2\lambda_1}) v^2$ | 0             | 125$^2$ (GeV)$^2$ |
| $m^2_{H^0}$      | $2\lambda_1 \omega^2 + \frac{\lambda_2^2}{2\lambda_1} v^2$ | $2\lambda_1 \omega^2$ | $\frac{\lambda_2^2}{2\lambda_1} v^2$ |
| $m^2_{H^\pm}$    | $\frac{\lambda_4}{2} (\omega^2 + v^2)$ | $\frac{\lambda_4}{2} \omega^2$ | $\frac{\lambda_4}{2} v^2$ |

In the effective potential, we must consider contributions from all fermions and bosons. But for fermions, we retain only the top and exotic quarks because their contributions dominate over those from the other fermions. Therefore, from the Lagrangian we acquire two motion equations according to $\omega$ and $v$,

\[
\partial^\mu \omega \partial_\mu \omega + \frac{\partial V_0(\omega)}{\partial \omega} + \sum \frac{\partial m^2_{bosons}(\omega)}{\partial \omega} W^\mu W_\mu + \sum \frac{\partial m_{exotic-quarks}(\omega)}{\partial \omega} Q\bar{Q} = 0, \tag{33}
\]
\[
\partial^\mu v \partial_\mu v + \frac{\partial V_0(v)}{\partial v} + \sum \frac{\partial m^2_{bosons}(v)}{\partial v} W^\mu W_\mu + \frac{\partial m_{top-quark}(v)}{\partial v} t\bar{t} = 0. \tag{34}
\]

From Eq. (33), using Bose-Einstein and Fermi-Dirac distributions respectively for bosons and fermions to average over space, we obtain the one-loop effective potential $V_{eff}(\omega)$ at high temperatures:
\[ V_{\text{eff}}(\omega) = V_0(\omega) + \frac{1}{64\pi^2} \left[ 6m_1^4(\omega) \ln \frac{m_1^2(\omega)}{Q^2} + 6m_Y(\omega) \ln \frac{m_Y^2(\omega)}{Q^2} \right. \\
+ 3m_{Z_2}(\omega) \ln \frac{m_{Z_2}^2(\omega)}{Q^2} + m_{H_1}^4(\omega) \ln \frac{m_{H_1}^2(\omega)}{Q^2} \\
+ 2m_{H_2}^4(\omega) \ln \frac{m_{H_2}^2(\omega)}{Q^2} - 36m_0^4(\omega) \ln \frac{m_0^2(\omega)}{Q^2} \right] \\
+ \frac{T^4}{4\pi^2} \left[ 6F_-(\frac{m_Y(\omega)}{T}) + 6F_-(\frac{m_Y(\omega)}{T}) + 3F_-(\frac{m_{Z_2}(\omega)}{T}) \right. \\
+ F_-(\frac{m_{H_0}(\omega)}{T}) + 2F_-(\frac{m_{H_2}(\omega)}{T}) + 36F_+(\frac{m_{H_2}(\omega)}{T}) \left], \right. \tag{35} \\
\]

in which \( m_Q \) indicates the masses of three exotic quarks, and the terms in the form \( F_+ \left( \frac{m}{T} \right) \) describe the thermal contributions of particles with masses \( m \). These terms are given by

\[ F_+ \left( \frac{m}{T} \right) = \int_0^\frac{\pi}{T} \alpha J^{(1)}_+ (\alpha, 0) d\alpha, \tag{36} \]

where

\[ J^{(1)}_+ (\alpha, 0) = 2 \int_0^\infty \frac{(x^2 - \alpha^2)^{1/2}}{e^x - 1} dx. \tag{37} \]

Similarly, from Eq. (34), we obtain the high-temperature effective potential \( V_{\text{eff}}(v) \):

\[ V_{\text{eff}}(v) = V_0(v) + \frac{1}{64\pi^2} \left[ 6m_1^4(v) \ln \frac{m_1^2(v)}{Q^2} + 6m_Y(v) \ln \frac{m_Y^2(v)}{Q^2} \right. \\
+ 3m_{Z_1}(v) \ln \frac{m_{Z_1}^2(v)}{Q^2} + m_{H_0}^4(v) \ln \frac{m_{H_0}^2(v)}{Q^2} + m_{H_1}^4(v) \ln \frac{m_{H_1}^2(v)}{Q^2} \\
+ 2m_{H_2}^4(v) \ln \frac{m_{H_2}^2(v)}{Q^2} - 12m_4^4(v) \ln \frac{m_4^2(v)}{Q^2} \right] \\
+ \frac{T^4}{4\pi^2} \left[ 6F_-(\frac{m_Y(v)}{T}) + 6F_-(\frac{m_Y(v)}{T}) + 3F_-(\frac{m_{Z_1}(v)}{T}) \right. \\
+ F_-(\frac{m_{H_0}(v)}{T}) + F_-(\frac{m_{H_2}(v)}{T}) + 2F_-(\frac{m_{H_2}(v)}{T}) + 12F_+(\frac{m_{H_2}(v)}{T}) \right], \tag{38} \\
\]

in which \( m_t \) indicates the mass of the top quark.

Eqs. (31)-(35) and (38) do not consist of any mixing between \( \omega \) and \( v \). Therefore, we can write the total effective potential in the E331 model as

\[ V_{\text{eff}}^{E331} = V_{\text{eff}}(\omega) + V_{\text{eff}}(v). \tag{39} \]
The effective potentials $V_{\text{eff}}(\omega)$ and $V_{\text{eff}}(v)$ seem to depend on the arbitrary scales $Q'$ and $Q$ respectively. However, by the same reasoning as in Eqs. (35) and (38), we can show that the structure of these potentials remain unchanged for the changes in scales. At zero temperature, all thermal contributions vanish, and due to the quartic form of $V_0(\omega)$ and $V_0(v)$, we can rewrite Eqs. (35) and (38) as

$$V_{\text{eff}}^0(\omega) = \lambda_R' \omega^4 + M_R^2 \omega^2 + \Lambda_R' + \frac{1}{64\pi^2} \left[ 6m_Y^4(\omega) \ln \frac{m_Y^2(\omega)}{Q'^2} + 6m_X^4(\omega) \ln \frac{m_X^2(\omega)}{Q'^2} \right. $$

$$+ 3m_Z^4(\omega) \ln \frac{m_Z^2(\omega)}{Q'^2} + m_Y^4(\omega) \ln \frac{m_Y^2(\omega)}{Q'^2} $$

$$+ 2m_H^4(\omega) \ln \frac{m_H^2(\omega)}{Q'^2} - 36m_Q^4(\omega) \ln \frac{m_Q^2(\omega)}{Q'^2} \right] , \quad (40)$$

and

$$V_{\text{eff}}^0(v) = \lambda_R v^4 + M_R v^2 + \Lambda_R + \frac{1}{64\pi^2} \left[ 6m_W^4(v) \ln \frac{m_W^2(v)}{Q^2} + 6m_Y^4(v) \ln \frac{m_Y^2(v)}{Q^2} \right. $$

$$+ 3m_Z^4(v) \ln \frac{m_Z^2(v)}{Q^2} + m_Y^4(v) \ln \frac{m_Y^2(v)}{Q^2} $$

$$+ 2m_H^4(v) \ln \frac{m_H^2(v)}{Q^2} \right] , \quad (41)$$

where $\lambda_R', M_R', \Lambda_R', \lambda_R, M_R, \text{and} \Lambda_R$ are the renormalized constants. The changes such as $Q' \rightarrow k'Q'$ (or $Q \rightarrow \kappa Q$) induce the terms which contain $\kappa'$ (or $\kappa$) and are proportional to $m_{\text{bosen}}^4(\omega) \sim \omega^4$ (or $m_{\text{bosen}}^4(v) \sim v^4$). Those terms can be absorbed by $\lambda_R'$ (or $\lambda_R$). This makes the physics remain the same.

By this reason, we can put $Q' = \epsilon' \omega_0$ and $Q = \epsilon \omega_0$ into Eqs. (40) and (41), respectively. Combining the terms which contain $\epsilon'$ and $\epsilon$ with the renormalized constants, we have:

$$V_{\text{eff}}^0(\omega) = \frac{\lambda_0'}{4} \omega^4 + M_0'^2 \omega^2 + \Lambda_0' + \frac{1}{64\pi^2} \left[ 6m_Y^4(\omega) \ln \frac{\omega^2}{\omega_0^2} + 6m_X^4(\omega) \ln \frac{\omega^2}{\omega_0^2} \right. $$

$$+ 3m_Z^4(\omega) \ln \frac{\omega^2}{\omega_0^2} + m_Y^4(\omega) \ln \frac{\omega^2}{\omega_0^2} $$

$$+ 2m_H^4(\omega) \ln \frac{\omega^2}{\omega_0^2} - 36m_Q^4(\omega) \ln \frac{\omega^2}{\omega_0^2} \right] , \quad (42)$$

and

$$V_{\text{eff}}^0(v) = \frac{\lambda_0}{4} v^4 + M_0 v^2 + \Lambda_0 + \frac{1}{64\pi^2} \left[ 6m_W^4(v) \ln \frac{v^2}{v_0^2} + 6m_Y^4(v) \ln \frac{v^2}{v_0^2} \right. $$

$$+ 3m_Z^4(v) \ln \frac{v^2}{v_0^2} + m_Y^4(v) \ln \frac{v^2}{v_0^2} $$

$$+ 2m_H^4(v) \ln \frac{v^2}{v_0^2} \right] , \quad (43)$$
where $\lambda_0$, $M_0^2$, $\Lambda_0$, $\lambda_0$, $M_0^2$, $\Lambda_0$ are the parameters those can be specified from the conditions (52) and (58). And we acquire:

$$
\lambda_0 = \left\{ \frac{m_{H_1^0}^2(\omega_0)}{2\omega_0^2} - \frac{3}{32\pi^2} (6m_Y^4(\omega_0) + 6m_X^4(\omega_0) + 3m_{Z_2}^4(\omega_0) + m_{H_1^0}^4(\omega_0) + 2m_{H_2^+}^4(\omega_0) - 36m_Q^4(\omega_0)) \right\},
$$

$$
M_0^2 = \left\{ \frac{1}{4} m_{H_1^0}^2(\omega_0) + \frac{1}{32\pi^2\omega_0^2} (6m_Y^4(\omega_0) + 6m_X^4(\omega_0) + 3m_{Z_2}^4(\omega_0) + m_{H_1^0}^4(\omega_0) + 2m_{H_2^+}^4(\omega_0) - 36m_Q^4(\omega_0)) \right\},
$$

$$
\Lambda_0 = \frac{\omega_0^2}{4} \left\{ \frac{m_{H_1^0}^2(\omega_0)}{2} - \frac{1}{32\pi^2\omega_0^2} (6m_Y^4(\omega_0) + 6m_X^4(\omega_0) + 3m_{Z_2}^4(\omega_0) + m_{H_1^0}^4(\omega_0) + 2m_{H_2^+}^4(\omega_0) - 36m_Q^4(\omega_0)) \right\},
$$

$$
\lambda_0 = \left\{ \frac{m_{H_0}^2(v_0) + m_{H_1^0}^2(v_0)}{2v_0^2} - \frac{3}{32\pi^2} (6m_W^4(v_0) + 6m_Y^4(v_0) + 3m_{Z_1}^4(v_0) + m_{H_0}^4(v_0) + m_{H_1^0}^4(v_0) + 2m_{H_2^+}^4(v_0) - 12m_t^4(v_0)) \right\},
$$

$$
M_0^2 = \left\{ \frac{-m_H^2(v_0) + m_{H_0}^2(v_0)}{4} + \frac{1}{32\pi^2v_0^2} (6m_W^4(v_0) + 6m_Y^4(v_0) + 3m_{Z_1}^4(v_0) + m_{H_0}^4(v_0) + m_{H_1^0}^4(v_0) + 2m_{H_2^+}^4(v_0) - 12m_t^4(v_0)) \right\},
$$

$$
\Lambda_0 = \frac{v_0^2}{4} \left\{ \frac{m_{H_0}^2(v_0) + m_{H_1^0}^2(v_0)}{2} - \frac{1}{32\pi^2v_0^2} (6m_W^4(v_0) + 6m_Y^4(v_0) + 3m_{Z_1}^4(v_0) + m_{H_0}^4(v_0) + m_{H_1^0}^4(v_0) + 2m_{H_2^+}^4(v_0) - 12m_t^4(v_0)) \right\}.
$$

In the special case, when $M_0^2 = 0$, the potential (43) reduces to the Coleman-Weinberg potential.

**IV. ELECTROWEAK PHASE TRANSITION**

In sequence of SSB of the E331 model, the SSB which breaks the gauge symmetry $SU(3)_L \otimes U(1)_X$ down to the $SU(2)_L \otimes U(1)_Y$ through $\chi_3^0$ generates the masses for the
exotic quarks, the heavy gauge bosons $X^0$ and $Z_2$, and gives the first part of mass for $Y^\pm$. The SSB which breaks the symmetry $SU(2)_L \otimes U(1)_Y$ down to the $U(1)_Q$ through $\chi^0_1$ and $\phi^0_2$ generates the masses for the SM particles and gives the last part of mass for $Y^\pm$. Because $\omega_0 \sim O(1)$ TeV, $u_0 \sim O(1)$ GeV, and $v_0 = 246$ GeV \cite{17, 20}, the breaking $SU(3) \to SU(2)$ occurs before the breaking $SU(2) \to U(1)$.

Associated with this sequence of SSB, a sequence of EWPT takes place with the transition $SU(3) \to SU(2)$ at the scale of $\omega_0$ and the transition $SU(2) \to U(1)$ at the scale of $v_0$ as the Universe cools down from the hot big bang. Our analysis so far shows that the former is the first transition which depends only on $\omega$, while the latter is the second transition which depends only on $v$.

From Table I, the gauge bosons $X^0$ and $Z_2$ are only involved in the first transition, the gauge bosons $W^\pm$, $Z_1$ and $H^0$ are only involved in the second transition, but the bosons $Y^\pm$, $H^0_1$, and $H^+_2$ are involved in both transitions. The total mass of $Y^\pm$ – i.e. $m_{Y^\pm}(\omega, v)$, whose formula is given by \cite{12} – is generated as follows. As the Universe is at the $\omega_0$ scale and the EWPT $SU(3) \to SU(2)$ happens, $Y^\pm$ eats the Goldstone boson $\chi^\pm_2$ of the triplet $\chi$ to acquire the first part of mass, $m_{Y^\pm}(\omega)$. When the Universe cools to the $v_0$ scale and the EWPT $SU(2) \to U(1)$ is turned on, $Y^\pm$ eats the Goldstone boson $\rho^\pm_1$ of triplet $\phi$ and get the last part of mass, $m_{Y^\pm}(v)$.

A. Phase transition $SU(3) \to SU(2)$

Taking place at the scale of $\omega_0$ which is chosen to be in the range $1 - 5$ TeV, the EWPT $SU(3) \to SU(2)$ involves exotic quarks and heavy bosons, without the involvement of the SM particles. From Eq. \cite{33}, the high-temperature effective potential of the EWPT can be rewritten as

\[
V_{eff}(\omega) = D'(T^2 - T^2_0)\omega^2 - E'T\omega^3 + \frac{\chi'_T}{4}\omega^4,
\]  

(50)
function of $m$ \( S \) \((1)-(5), we present the contours of $F$ the ansatz in \[12\] and assume $V$ \(\omega\) which is a function of three unknown masses, $m$

From the conditions \((52), we have the minima of the effective potential \((50):$\]

\[
V_{\text{eff}}(\omega) = 0; \quad \frac{\partial V_{\text{eff}}(\omega)}{\partial \omega} \Big|_{\omega = \omega_0} = 0; \quad \frac{\partial^2 V_{\text{eff}}(\omega)}{\partial \omega^2} \Big|_{\omega = \omega_0} = m_{H_0}^2(\omega) \Big|_{\omega = \omega_0}. \tag{52}
\]

From the conditions \((52), we have the minima of the effective potential \((50):$\]

\[
\omega = 0, \quad \omega \equiv \omega_c = \frac{2E'T_c'}{\lambda_T'}, \tag{53}
\]

where $\omega_c$ is a critical VEV of $\chi$ at the broken state, and $T'_c$ is the critical temperature of phase transition which is given by

\[
T'_c = \frac{T_0'}{\sqrt{1 - E'^2/D'T'_c}}. \tag{54}
\]

Now, we consider the phase transition strength:

\[
S' = \frac{\omega_c}{T_c'} = \frac{2E'}{\lambda_T'}, \tag{55}
\]

which is a function of three unknown masses, $m_{H_0}$, $m_{H^\pm}$ and $m_Q$. For simplicity, we follow the ansatz in \[12\] and assume $m_{H^\pm} = m_Q$. Then we plot the transition strength $S'$ as the function of $m_{H_0}^2(\omega_c)$ and $m_{H^\pm}^2(\omega_c)$ with $\omega_c$ is in the range from 1 TeV to 5 TeV. In Figs. \[1\]-\[5\], we present the contours of $S'$ in the $(m_{H^\pm}, m_{H_0}^2)$-plane; each Fig. corresponds with a
Bảng II. The mass ranges of $H_1^0$ and $H_2^{\pm}$ for the EWPT $SU(3) \rightarrow SU(2)$ to be the first-order phase transition, and their upper bounds as required by the condition $m_{\text{boson}} < 2.2 \times T_c'$. 

| $\omega$ [TeV] | $T_c'$ [GeV] | $m_{H_1^0}$ [GeV] | $m_{H_2^{\pm}}$ [GeV] | Upper bound [GeV] |
|----------------|--------------|-------------------|-----------------------|------------------|
| 1              | 350          | $0 < m_{H_1^0} < 300$ | $0 < m_{H_2^{\pm}} < 720$ | 770              |
| 2              | 650          | $0 < m_{H_1^0} < 600$ | $0 < m_{H_2^{\pm}} < 1440$ | 1430             |
| 3              | 950          | $0 < m_{H_1^0} < 900$ | $0 < m_{H_2^{\pm}} < 2150$ | 2090             |
| 4              | 1300         | $0 < m_{H_1^0} < 1200$ | $0 < m_{H_2^{\pm}} < 2870$ | 2860             |
| 5              | 1600         | $0 < m_{H_1^0} < 1500$ | $0 < m_{H_2^{\pm}} < 3590$ | 3520             |

The smooth contours are the sets of the $(m_{H_2^{\pm}}, m_{H_1^0})$-pairs which make $S' > 1$ and then the EWPT $SU(3) \rightarrow SU(2)$ to be the first-order phase transition. The uneven contours are the sets of the $(m_{H_2^{\pm}}, m_{H_1^0})$-pairs which are unusable because they make $S' \rightarrow \infty$. Our results show that the heavy particle masses must be in the range of a few TeV, and the strength of the first-order phase transition $SU(3) \rightarrow SU(2)$ is in the range $1 < S' < 13$. 

According to Ref. [25], the accuracy of a high-temperature expansion for the effective potential such as that in Eq. (50) will be better than 5% if $m_{\text{boson}} < 2.2$, where $m_{\text{boson}}$ is the relevant boson mass. This requirement sets the "upper bounds" of the mass ranges of $H_1^0(\omega)$ and $H_2^{\pm}(\omega)$. From Table II, this requirement is satisfied by all mass ranges of $H_1^0$, while it narrows slightly most of the mass ranges of $H_2^{\pm}$.

From Eq. (55), the phase transition strength $S'$ depends on the parameters $E'$ and $\chi_{T'_c}$. From Eq. (51), $E'$ expresses the contributions of the new bosons while $\chi_{T'_c}$ includes the contributions of the exotic quarks to the phase transition strength. Therefore, the new bosons and exotic quarks can be triggers for the EWPT $SU(3) \rightarrow SU(2)$ to be the first-order.

### B. Phase transition SU(2) → U(1)

Occurring at the scale $v_0 = 246$ GeV, the phase transition $SU(2) \rightarrow U(1)$ does not involve the exotic quarks or the boson $X^0$. In this stage, the contribution from $Y^{\pm}$ is equal to that from $W^{\pm}$. The effective potential is given by Eq. (38). We write the high-temperature expansion of this potential as

\[ \text{Eq. (38)} \]
Hình 1. The contours of $S' = \frac{\langle \sigma v \rangle}{\langle n \rangle}$ in the case $\omega_c = 1$ TeV. Solid (and smooth) contour: $S' = 1$; dashed contour: $S' = 2$; dotted contour: $S' = 3$; dotted-dashed contour: $S' = 4$; uneven contour: $S' \to \infty$. In this case, the mass ranges of $m_{H_1^0}$ and $m_{H_2^\pm}$ for the first-order phase transition are $0 < m_{H_1^0} < 300$ GeV and $0 < m_{H_2^\pm} < 720$ GeV, respectively.

Hình 2. The contours of $S' = \frac{\langle \sigma v \rangle}{\langle n \rangle}$ in the case $\omega_c = 2$ TeV. Solid (and smooth) contour: $S' = 1$; dashed contour: $S' = 2$; dotted contour: $S' = 3$; dotted-dashed contour: $S' = 4$; uneven contour: $S' \to \infty$. The mass ranges of $m_{H_1^0}$ and $m_{H_2^\pm}$ for the first-order phase transition are $0 < m_{H_1^0} < 600$ GeV and $0 < m_{H_2^\pm} < 1440$ GeV, respectively.

$$V_{eff}(v) = D(T^2 - T_0^2)v^2 - ET|v|^3 + \frac{\lambda_T}{4}v^4,$$

(56)
Hình 3. The contours of $S' = \frac{\omega_c}{T'_{c}}$ in the case $\omega_c = 3 \text{ TeV}$. Solid (and smooth) contour: $S' = 1$; dashed contour: $S' = 2$; dotted contour: $S' = 3$; dotted-dashed contour: $S' = 4$; uneven contour: $S' \to \infty$. The mass ranges of $m_{H_0}$ and $m_{H_2}^\pm$ for the first-order phase transition are $0 < m_{H_0} < 900 \text{ GeV}$ and $0 < m_{H_2}^\pm < 2150 \text{ GeV}$, respectively.

Hình 4. The contours of $S' = \frac{\omega_c}{T'_{c}}$ in the case $\omega_c = 4 \text{ TeV}$. Solid (and smooth) contour: $S' = 1$; dashed contour: $S' = 2$; dotted contour: $S' = 3$; dotted-dashed contour: $S' = 4$; uneven contour: $S' \to \infty$. The mass ranges of $m_{H_1}$ and $m_{H_2}^\pm$ for the first-order phase transition are $0 < m_{H_1} < 1200 \text{ GeV}$ and $0 < m_{H_2}^\pm < 2870 \text{ GeV}$, respectively.
Hình 5. The contours of $S' = \frac{\partial V}{\partial v}$ in the case $\omega_c = 5$ TeV. Solid (and smooth) contour: $S' = 1$; dashed contour: $S' = 2$; dotted contour: $S' = 3$; dotted-dashed contour: $S' = 4$; uneven contour: $S' \to \infty$. The mass ranges of $m_{H_0}^0$ and $m_{H_2}^0$ for the first-order phase transition are $0 < m_{H_0}^0 < 1500$ GeV and $0 < m_{H_2}^0 < 3590$ GeV, respectively.

in which

$$D = \frac{1}{24 v_0^2} \left[ 6m_W^2(v_0) + 6m_Y^2(v_0) + 3m_{Z_1}^2(v_0) + m_{H_0}(v_0) + m_{H_1}^0(v_0) + 2m_{H_2}^0(v_0) + 6m_t^2(v_0) \right],$$

$$T_0^2 = \frac{1}{D} \left\{ \frac{m_{H_1}^2(v_0) + m_{H_1}^0(v_0)}{4} - \frac{1}{32\pi^2 v_0^2} \left( 6m_W^4(v_0) + 6m_Y^4(v_0) + 3m_{Z_1}^4(v_0) \right. \right.$$  

$$+ m_{H_0}^4(v_0) + m_{H_1}^4(v_0) + 2m_{H_2}^4(v_0) - 12m_t^4(v_0) \left. \right) \right\},$$

$$E = \frac{1}{12\pi v_0^2} \left( 6m_W^2(v_0) + 6m_Y^2(v_0) + 3m_{Z_1}^2(v_0) + m_{H_0}^2(v_0) + m_{H_1}^2(v_0) + 2m_{H_2}^2(v_0) \right),$$

$$\lambda_T = \frac{m_{H_0}^2(v_0) + m_{H_1}^2(v_0)}{2v_0^2} \left\{ 1 - \frac{1}{8\pi^2 v_0^2(m_{H_0}^2(v_0) + m_{H_1}^2(v_0))} \left[ 6m_W^4(v_0) \ln \frac{m_W^2(v_0)}{bT^2} \right. \right.$$  

$$+ 6m_Y^4(v_0) \ln \frac{m_Y^2(v_0)}{bT^2} + 3m_{Z_1}^4(v_0) \ln \frac{m_{Z_1}^2(v_0)}{bT^2} + m_{H_0}^4(v_0) \ln \frac{m_{H_0}^2(v_0)}{bT^2} \right.$$  

$$\left. + 2m_{H_2}^4(v_0) \ln \frac{m_{H_2}^2(v_0)}{bT^2} - 12m_t^4(v_0) \ln \frac{m_t^2(v_0)}{bT^2} \right] \right\},$$

where $v_0$ is the value at which the zero-temperature effective potential $V_{eff}^{\omega_K}(v)$ gets the minimum. Here, we acquire $V_{eff}^{\omega_K}(v)$ from $V_{eff}(v)$ in Eq. (38) by neglecting all terms in the form $F_\pm \left( \frac{m}{T} \right)$.

From the minimum conditions for $V_{eff}^{\omega_K}(v)$

$$V_{eff}^{\omega_K}(v_0) = 0, \quad \frac{\partial V_{eff}^{\omega_K}(v)}{\partial v} \bigg|_{v=v_0} = 0, \quad \frac{\partial^2 V_{eff}^{\omega_K}(v)}{\partial v^2} \bigg|_{v=v_0} = \left[ m_{H_0}^2(v) + m_{H_1}^2(v) \right] \bigg|_{v=v_0}, \quad (58)$$
we can see that in this EWPT, $m_{H_0}^2(v)$ and $m_{H_1^0}^2(v)$ generate the masses of the SM particles and the last mass part of $Y^\pm$. We also have the minima of the effective potential (56):

\[ v = 0, \quad v \equiv v_c = \frac{2E}{\lambda T_c}, \]

where $v_c$ is the critical VEV of $\phi$ at the broken state, and $T_c$ is the critical temperature of phase transition which is given by

\[ T_c = \frac{T_0}{\sqrt{1 - E^2/D\lambda T_c}} \]  

(60)

We investigate the phase transition strength

\[ S = \frac{v_c}{T_c} = \frac{2E}{\lambda T_c} \]

(61)
of this EWPT. In the limit $E \to 0$, the transition strength $S \to 0$ and the phase transition is a second-order. To have a first-order phase transition, we requires $S \geq 1$. We plot $S$ as a function of $m_{H_1^0}(v_0)$ and $m_{H_2^\pm}(v_0)$. As shown in Fig. 6 for the masses of $H_2^\pm$ and $H_1^0$ which are respectively in the ranges $250 \text{ GeV} < m_{H_2^\pm}(v) < 1200 \text{ GeV}$ and $0 \text{ GeV} < m_{H_1^0}(v) < 620 \text{ GeV}$, the transition strength is in the range $1 \leq S < 3$.

Hình 6. The contours of transition strength $S = \frac{2E}{\lambda T_c}$. Solid smooth contour: $S = 1$; dashed smooth contour: $S = 1.1$; dotted smooth contour: $S = 1.15$; dash-dotted smooth contour: $S = 1.5$; even contours: $S \to \infty$. The mass ranges of $m_{H_1^0}$ and $m_{H_2^\pm}$ for the EWPT $SU(2) \to U(1)$ to be the first-order are $0 \text{ GeV} < m_{H_1^0}(v) < 620 \text{ GeV}$ and $250 \text{ GeV} < m_{H_2^\pm}(v) < 1200 \text{ GeV}$, respectively.

Considering the requirement for the high-temperature expansion to be applicable on the effective potential (38), $\frac{m_{H_1^0}}{T} < 2.2$, we show in Fig. 7 that with $T = T_c \sim 130 \text{ GeV},$
Hình 7. The condition \( \frac{m_{boson}}{f} < 2.2 \) narrows the mass ranges of \( H_2^\pm \) and \( H_1^0 \) as well as the range of transition strength.

the mass ranges of \( H_2^\pm \) and \( H_1^0 \) are respectively narrowed to:

\[
255 \text{ GeV} < m_{H_2^\pm} < 280 \text{ GeV},
\]

and

\[
0 \text{ GeV} < m_{H_1^0} < 58 \text{ GeV}.
\]

Corresponding with these ranges of mass, the range of phase-transition strength is narrowed to \( 1 \leq S < 1.15 \). Thus the EWPT \( SU(2) \rightarrow U(1) \) is the first-order phase transition, but it seems quite weak.

As we can see in Eqs. (61) and (57), the new bosons contribute to the phase transition strength \( S \) via the parameters \( E \) and \( \lambda_{T_c} \). Hence these new bosons can be triggers for the EWPT \( SU(2) \rightarrow U(1) \) to be the first-order.

In Fig. 8 we illustrate the dependence of the effective potential \( V_{eff}(v) \) on the temperature. When the Universe cools through the phase-transition critical temperature \( T_c \), the Higgs field \( v \) tends to get a nonzero VEV \( v_0 \) which is in the range \( 0 < v_0 < 246 \text{ GeV} \), and the second minimum of \( V_{eff}(v) \) gradually appears at \( v_0 \). As the temperature drops from \( T_c \), the second minimum becomes lower and the first minimum gradually disappears, while the VEV \( v_0 \) tends to 246 GeV. The tendency of \( v_0 \) can be seen in Fig. 9 where we show that
Hình 8. The dependence of the effective potential $V_{eff}(v)$ on the temperature. With $m_{H_1^0}(v) = 50$ GeV and $m_{H_2^0}(v) = 280$ GeV, we have the critical temperature $T_c = 127.974$ GeV and the phase-transition strength $S = 1.03$. Solid line: $T_c$; lines above the solid line: $T > T_c$; lines under the solid line: $T < T_c$.

$v_0$ reaches to 246 GeV for the temperatures which are far below $T_c$. At 0°K, the non-zero minimum locates exactly at $v_0 = 246$ GeV. This result is consistent with the SM.

C. Constraint on the mass of the charged Higgs boson

From the EWPT $SU(2) \rightarrow U(1)$, we have derived the mass ranges of $H_2^0(v)$ and $H_1^0(v)$ in Eqs. (62) and (63). So we have

$$0 \text{ GeV} < m_{H_1^0} = \sqrt{m_{H_1^0}^2(v) + m_{H_1^0}^2(\omega)} < 1501.12 \text{ GeV}, \quad (64)$$
Hình 9. The tendency of nonzero minimum for lower temperatures. We choose $m_{H_1}(v) = 50 \text{GeV}$, $m_{H_2}(v) = 280 \text{GeV}$. Dot-dashed line: $T = 50 \text{GeV}$. Dotted line: $T = 10 \text{GeV}$. Solid line: $T = 1 \text{GeV}$. $v_0$ reaches to 246 GeV as the temperature decreases.

and we obtain

$$2.149 < \lambda_4 < 2.591,$$

and

$$0 < \frac{\lambda_3}{2\lambda_1} < 0.0556,$$  \hspace{1cm} (66)

From the phase transition $SU(3) \rightarrow SU(2)$, we have also derived

$$0 < \lambda_4 < 10.3,$$  \hspace{1cm} (67)

and

$$0 < \lambda_1 < 0.45,$$  \hspace{1cm} (68)

for any $\omega$. Eqs. (65)-(68) lead to $2.149 < \lambda_4 < 2.591$; $0 < \lambda_1 < 0.45$ and $0 < \frac{\lambda_3}{2\lambda_1} < 0.0556$.

V. CONCLUSION AND OUTLOOKS

We have investigated the EWPT in the E331 model using the high-temperature effective potential. Although the effective potential in the model depends complicatedly on three VEVs, $u$, $\omega$, and $v$, it can be transformed to a sum of two parts so that each part depends
only on $\omega$ or $v$, which corresponds a stage of SSB. Thanks to that the EWPT can be seen as a sequence of two EWPTs. The first, $SU(3) \rightarrow SU(2)$, takes place at the energy scale $\omega_0$ to generate the masses for the exotic quarks, the heavy gauge bosons $X^0$ and $Z_2$, as well as a mass part of $Y^\pm$. The second, $SU(2) \rightarrow U(1)$, occurs at the scale $v_0$ to give the masses for the SM particles and the remained mass part of $Y^\pm$.

At the TeV scale, the EWPT $SU(3) \rightarrow SU(2)$ is strengthened by the new bosons and the exotic quarks to be the strongly first-order; if the masses of these new particles are about $10^2 - 10^3$ GeV, the phase transition strength is in the range $1 - 13$. As the energy is lowered to the scale of $10^2$ GeV, the EWPT $SU(2) \rightarrow SU(1)$ is strengthened by only the new bosons; with the contributions of the mass parts from $H_1^0$, $H_2^\pm$ and $Y^\pm$ which are in the ranges $10 - 10^2$ GeV, the strength of this transition is about $1 - 1.15$. Therefore, both EWPTs can be the first-order; the $SU(3) \rightarrow SU(2)$ appears very strong, while the $SU(2) \rightarrow SU(1)$ seems quite weak.

However, both of these first-order EWPTs can be sufficiently strong to provide B violation necessary for baryogenesis, as shown via the parameter ranges which we have specified. If $H_1^0$ and $H_2^\pm$ exist, their contributions to the strengths of each EWPT are meaningly large. In this case, the sequence of strongly first-order EWPTs in the model may provide a source of large deviations from thermal equilibrium. And the model may fully describe the continual existence of BAU since being generated in the early Universe.

In the next works, we will investigate the electroweak sphalerons as well as the C- and CP-violating interactions to know if the model possesses all necessary components for EWBG.
