Abstract
Background: There are few contemporary epidemiological data on stroke for Central Europe. We performed a population-based study evaluating the incidence of stroke, stroke types, and ischemic stroke (IS) subtypes in Brno, the second biggest city in the Czech Republic (CR).

Methods: Using the National Registry of Hospitalized Patients, and hospital databases, we identified all patients hospitalized with a stroke diagnosis in Brno hospitals in 2011. For Brno residents with validated stroke diagnosis, we calculated (a) the overall incidence of hospitalized stroke, (b) incidence rates for IS, subarachnoid hemorrhage (SAH) and intracerebral hemorrhage (ICH), and (c) incidence rates for IS subtypes. We calculated the average annual age- and sex-standardized incidence (European Standard Population and World Health Organization), to compare our results with other studies.

Results: The overall crude incidence of stroke in Brno was 213/100,000 population. The incidence of stroke for stroke types were as follows: SAH, 6.9; ICH, 26.4; and IS, 180 cases per 100,000 population, respectively. The WHO-standardized annual stroke incidence was 107 for all strokes and 88 for IS, 14.4 for ICH, and 5 for SAH. For IS subtypes, the WHO-standardized incidence was large artery atherosclerosis 25.8, cardioembolism 27.8, lacunar 21.6, other determined etiology 6.2, and undetermined etiology 6.5 cases per 100,000 population.

Conclusions: The stroke incidence is lower than that previously reported for the CR and Eastern Europe probably reflecting socioeconomic changes in post-communistic countries in the region. These findings could contribute to stroke prevention strategies and influence health policies.

Introduction

Stroke is the second leading cause of death worldwide, and a significant increase in cerebrovascular disease occurrence is expected [1]. The incidence rates of stroke vary between countries [2]. The former communist coun-

tries in Central and Eastern Europe including the Czech Republic (CR) had reportedly higher stroke incidence compared to Western Countries, but reliable, current epidemiological data are missing (Global Burden of Disease Study 2010 [GBD]) [3].

The CR, the postcommunist country in Central Europe, underwent extensive changes in lifestyle, stroke management, and treatment of stroke risk factors after the collapse of the Iron Curtain in 1989. Specialized stroke centers were accredited in 2010 [4], quality control is being performed, and the management of stroke risk factors improved significantly (decrease in the prevalence of smoking, in total cholesterol, and in blood pressure and improved hypertension control) [5]. It would be anticipated that such socioeconomic changes may be reflected in stroke incidence.

Previously, we reported the incidence of hospitalized stroke in the CR using the validated nationwide registry of all hospitalized patients [6, 7]. We performed a population-based study to assess the stroke incidence rates (SIR) for first-ever stroke, stroke types, and ischemic stroke (IS) subtypes in Brno.

Methods

This is a population-based study evaluating the incidence of stroke, stroke types, and IS subtypes in Brno, CR.

Brno

Brno, with 378,968 residents, is the second largest city in the CR [8]. In Brno, there are 4 hospitals with certified stroke units (St Anne’s University Hospital, University Hospital Brno, Hospital of Merciful Brothers, and Military Hospital Brno). All 4 hospitals participated in our study.

National Registry of Hospitalized Patients [6]

National Registry of Hospitalized Patients (NRHOSP) is a nationwide registry that has been previously validated for stroke diagnoses [6]. All inpatient medical facilities are legally mandated to prospectively register all completed inpatient admissions into the NRHOSP.

Design

All patients hospitalized with stroke in Brno hospitals in 2011 were identified through the NRHOSP. Discharge summaries were retrieved from hospital electronic databases and reviewed. The completeness of stroke ascertainment in our study was assessed at the national (nationwide registry NRHOSP) as well as regional level (4 cooperating hospitals’ patient databases). We included only patients (1) hospitalized in Brno hospitals; (2) legal residents of Brno city; (3) with confirmed stroke diagnosis (International Classification of Diseases Tenth Revision [ICD-10], IS [I63], subarachnoid hemorrhage [SAH, I60], and intracerebral hemorrhage [ICH, I61]); (4) with stroke event that occurred between January 1 and December 31, 2011; and (5) with first time stroke events. A group of cerebrovascular neurologists assigned stroke type and IS subtype using TOAST criteria based on clinical history, documented neurological examination, and the results of diagnostic and radiographic studies (brain imaging [CT/MRI], cardiac imaging [echocardiography, either transthoracic or transesophageal], duplex imaging of extracranial arteries, CT or MR angiography, electrocardiogram [ECG], ECG monitoring via telemetry, Holter monitoring, and relevant blood tests). In case of a disagreement, a senior stroke neurologist made the final decision on the IS subtype.

Definitions

We used the World Health Organization (WHO) definition for stroke: rapidly developing clinical signs of focal or global disturbance of cerebral function, lasting more than 24 h or until death, and with no apparent nonvascular cause [9]. We did not use the new tissue-based definition to allow comparison with prior studies [10]. To distinguish between IS, ICH, and SAH, CT, MRI, autopsy report, spinal fluid examination, and/or surgical data were used. We assessed IS subtypes using the TOAST criteria: (1) large artery atherosclerosis (LAA), (2) cardioembolism (CE), (3) lacunar, (4) stroke of other determined etiology (stroke-other), and (5) stroke of undetermined etiology (stroke-undetermined).

Statistical Analysis

Descriptive statistics with confidence intervals (CIs) were calculated assuming normal approximation of the binomial distribution. Crude and standardized incidence rates were calculated in accordance with the CDC definitions. To compare our SIR with that observed in other studies, we standardized our SIR. Population standards used throughout this document were obtained from the WHO report [11], USA census [12], and the Eurostat report [13].Incidence rate calculations are based on Poisson distribution with mean equal to the observed number of events, and 95% CIs for incidence rates are based on $\chi^2$ approximation of the exact Poisson distribution confidence limits [25]. All crude, standardized, age- and sex-specific rates, and all descriptive statistics summarizing our population were calculated using R.

Results

According to NRHOSP and hospital databases, there were 2,230 potential stroke cases in Brno in 2011 [8]. After excluding ineligible patients (400 Brno non-residents, 278 Brno rural area residents, 452 with a non-stroke diagnosis, 292 recurrences or duplicates/rehospitalizations [repeat hospitalization in different departments–internal medicine, neurology, rehabilitation]), a total of 808 strokes were identified. Of these 808 stroke cases, there were 682 (84.4%) IS, 100 (12.4%) ICH, and 26 (3.2%) SAH. The distribution of IS subtypes (TOAST) was as follows: CE 237 (35%), LAA 189 (28%), lacunar 160 (23%), stroke-undetermined 49 (7%) and stroke-other 47 (7%). Mean age at stroke onset was 72.8 years (SD = 12.4), and...
Table 1. Incidence rates for stroke per 100,000 population in Brno in 2011

| Stroke type          | Crude incidence rate | Incidence adjusted for Czech population | Incidence adjusted to 2000 WHO standard | Incidence adjusted to 2000 USA population | Incidence adjusted to 2010 European population |

48.9% were women. Brain neuroimaging (CT and MRI) was available in 801 (99%) and 100 (12.4%) of the included patients, respectively. The overall crude SIR in Brno was 213 per 100,000 population. SIR for the 3 stroke types was as follows: SAH 6.9; ICH 26.4; and IS 180 per 100,000 population (Table 1).

The population size of the CR was 10,436,560 inhabitants based on the 2011 census [8]. The overall SIR adjusted for Czech population was 192; SIR for the 3 stroke types was SAH 6.8; ICH 24.2; and IS 161 per 100,000 population. Men had a higher SIR compared to women for total stroke (207 for men and 179 for women), ICH (25.1 vs. 23.4), and IS (176 vs. 149), while women had higher incidence of SAH (6.6 for men and 7.1 for women) compared with men. Among patients with IS, CE was the most common subtype with an incidence of 53.9, followed by LAA 45.8; lacunar 38.8; stroke-other 11.6; and stroke-undetermined 11.3 per 100,000 population. Sex distribution revealed that CE and stroke-unknown were higher in women, while LAA, lacunar, and stroke-other were more common in men (Tables 1–4). We noted an increase in overall SIR with age, ranging from 6 (in the age-group 0–44 years) to 62 (in the age-group 75–84 years) per 100,000 population.

The overall annual SIR in Brno adjusted to the 2000 USA Standard [11] was 107; the corresponding SIRs were SAH 5.0; ICH 14.4; and IS 113, per 100,000 population. The overall annual SIR in Brno adjusted to the 2010 European Standard [12] was 195; the corresponding SIRs were SAH 6.6; ICH 24.4; and IS 164, per 100,000 population (Table 1). The annual SIR in Brno adjusted to the 2000 USA Standard [11] and 2010 European Standard [12], IS subtypes, age and sex distributions, and 95% CI are available on the online-only data supplement.

### Discussion

To the best of our knowledge, this is the first population-based study on stroke and IS subtype incidence rates in the CR and in Central Europe. Recently, we evaluated the incidence of hospitalized stroke in the CR using the nationwide NRHOSP [7]. The CR nationwide study [7] and the current Brno population-based study present complementary stroke incidence data; SIR adjusted to the 2000 WHO World Standard [11] was 131 and 107 per 100,000 population, respectively. Both studies suggest that the SIR in the CR is comparable to other Western European countries [14, 15]. According to a recent systematic review [15], CR would rank in the second SIR quartile (Q2: 80–112).

The GBD estimates that in 2011, there were 22,636 incident cases of IS in the CR [16], corresponding to the incidence 215 per 100,000 population (95% CI 145–312).
Stroke Incidence in Brno, Czech Republic

[3], which is close to our previously presented estimates for the CR (21,943 incident cases of IS; crude incidence rate for IS 211 per 100,000 population) [7]. In this Brno study, we present a lower crude incidence of IS (180 per 100,000 population). Based on the 2011 census, the South Moravian Region (Brno) has the fifth lowest average age in the CR [8]. The lower stroke incidence in Brno (urban area) compared to other parts of the CR with higher SIRs (rural) could be due to the differences in prevalence of stroke risk factors, their management, and level of control and is in accordance with reported trends of lower SIRs in urban settings compared to rural areas [17].

For hemorrhagic strokes, GBD estimates that in 2011, the incidence was 54 (95% CI 35–81) [3] (ICH 39 and SAH 15) per 100,000 [16]. In this Brno study, we found lower crude incidence rates: ICH 26 and SAH 7 per 100,000. This difference may be related to differences in methodology. GBD utilized 119 stroke incidence studies to calculate regional- and country-specific estimates of incidence [1] with few incidence studies included from Central and Eastern Europe [18].

We noted an increase in SIR with age, which has been previously described and attributed to higher prevalence of vascular risk factors in the elderly [14]. Men had higher SIRs (226 vs. 201 per 100,000) and younger stroke onset (mean age [SD]: 70.5 [12.0] vs. 75.1 [12.2] years) in overall stroke, which is in accordance with recent reviews [14, 15]. Furthermore, men had higher incidence rates for ICH (26.8 vs. 26) and IS (192 vs. 168) in comparison to women, while women had a slightly higher incidence rate of SAH (7.1 vs. 6.6).

The 2 most common IS subtypes accounting for more than 60% of all the strokes were CE (35%) and LAA (28%), with lacunar in 23% and stroke-undetermined in 7%. Other population-based studies (Rochester [19], Erlangen [20, 21], and Oxford Vascular Study [22], Table 3) reported a similar frequency of CE (19–29%) [19–22] and lacunar (16–23%) [19–22] with a lower frequency of LAA (13–16%) [19–22] and higher prevalence of stroke-undetermined (35–42%) [19–22]. The incidence of IS subtype differed by gender, with a 2 times greater age-adjusted incidence rate of LAA in men, similar to the Erlangen study [20]; the Rochester study [19] reported an even greater SIR for LAA in men. The relatively low percentage of stroke-undetermined (7%) in our study in comparison with other studies (11–42%) [19–22] is presumably due to the extensive evaluation utilized to assess for stroke mechanism: (a) according to guidelines and Ministry of Health regulations, all patients with stroke in the CR must be admitted to certified stroke centers; in our study, 656 (81%) patients were treated in a certified stroke center; (b) stroke units within stroke centers routinely use prolonged ECG monitoring via telemetry and subsequent Holter monitoring, leading to detection of atrial fibrillation with resulting CE subtype; (c) 85% patients received at least 1 diagnostic test to detect large artery stenosis (LAA subtype); and (d) our patient population is hospital-based with a resulting low frequency of patients with minimal assessment for stroke etiology. All of these factors contributed to the higher detection of CE and LAA subtype and lower frequency of stroke-undetermined.

Our study has limitations. First, we did not include patients who may have had stroke but were not hospitalized or died before hospitalization. Hospitalization rates differ between countries (ranking from ~10% in Japan [23] to ~90% in Sweden [24]). However, in the CR, all stroke cases should be managed in the hospital, given the guidelines of the Czech Neurological Society [25] and official regulations that require every patient with a potential stroke event to be hospitalized in a specialized stroke unit, the effective stroke unit network [4], and the universal healthcare system (free of charge to the patient) [7]. Our community-based study combines registry data (NRHOSP), which has full national coverage and was previously validated [6], with hospitalization data from all Brno hospitals providing care for stroke patients. Nevertheless, the percentage of nonfatal and nonhospitalized stroke cases is reported to be around 4% in other population-based studies (Germany 4.5% [20]). If we account for these cases, there would not be a substantial difference in SIRs. Second, we might have missed Brno inhabitants who had a stroke while outside of Brno. However, this is a limitation of most population-based studies and likely would not have a significant impact on the overall incidence. Third, Brno is the second biggest city in the CR; this urban area may have different SIRs than rural areas, and these SIRs may not be applicable to the whole CR. The present Brno study reports slightly lower SIRs than the previous study for the entire CR [7]. This finding is in line with the generally observed trends of lower SIRs in urban areas [17]. Nevertheless, the SIRs in both studies are comparable, which further supports the high-quality healthcare system and effective stroke unit coverage throughout the CR as reported previously [4]. Fourth, this study aimed to ascertain stroke incidence and cannot address stroke recurrence rates. Last, the data date to the year 2011, which was chosen intentionally, given that the national census was performed that year.
Conclusions

We presented the first population-based assessment of the incidence of first-ever stroke, stroke types, and IS subtypes in Central Europe. These stroke incidence estimates are essential to the development of health policy, with the goal to improve the primary and secondary prevention of stroke in an era of growing stroke burden as the population ages.

Statement of Ethics

The present study conforms to the guidelines issued in the Declaration of Helsinki. This study was approved by the Institutional Ethics Committees (Ethics Committees of St Anne’s University Hospital, University Hospital Brno, Hospital of Merciful Brothers, Military Hospital Brno, and Institute of Health Information and Statistics of the CR, RF. 36v(2014)). Consent was waived by the IRB for this retrospective medical record review study, with no direct patient contact.
