Reproductive Performance of Japanese Quail Hens (Coturnixcoturnix japonica) Fed with Feed Restriction Regimes during Growth Period

RT Hertamawati1, Suyadi2*, E Soedjarwo2, O Sjofjan2

ABSTRACT

Reproductive performance of quail hens (Coturnixcoturnix japonica) at sexual maturity was evaluated following two feeding restriction programs (100%, 90% and 80% of ad libitum) and energy metabolism (EM) of ration: 2900 Kcal/kg and 2800 Kcal/kg between 2 weeks and 5 weeks of age with five replicates of 10 chicks per replicate. Body weight and feed conversion were measured weekly during feed restriction. After experimental feeding treatment, age at first egg, BW, egg weight, development of reproductive organ on sexual maturity were evaluated of one hen's quail per treatment. The results of the experiment indicated that the restricted feeding until 80% of ad libitum was consequently (p <0.01) delayed sexual maturity and influence the development of the reproductive organ. However, it did not show significant influence on the body weight of the first-laid egg and initial egg production. Restricted feeding at 90% of ad libitum and EM ration 2900 Kcal/kg showed the best results for quail feed management during growth.

Agricultural Science Digest (2019)

INTRODUCTION

Japanese quail is a breed for eggs and meat production. There are few studies published on egg production (Vali, 2008). However, reports on quail reproductive and growth are limited. It is well known that both protein and energy in poultry ration are considered the most expensive items in the cost of a complete feed, where energy alone contributes to about 70% of the total cost of poultry ration (Skinner et al., 1992).

Furthermore, both dietary energy and protein represent approximately 85% of the total feed cost (Gunawardana et al., 2008). Hence, it is to be expected that many programs will be made to reduce their use in the rations without lowering performance. Many of these restriction programs involve quantitative feed and energy feeding regimes.

Only a little or limited information was reported to deal with the use of qualitative restricted feeding as a nutritional approach to reducing the cost of feeds or problems associated with egg production in Japanese quail hens. Some studies have determined the effects of qualitative and quantitative feed restriction on growth performance of broiler chicken (Jang et al., 2009), reproductive performance (Anderson, 2010), ovary morphology and laying traits of turkey (Renema et al., 1999).

The advantages of restricted feeding over full feeding during the rearing period are usually considered to be greater the longer the laying flock is kept. Although feed restriction delayed the onset of egg production by approximately two days as compared to control (full fed) in quail production but early feed restriction significantly (p <0.05) affected first egg weight and the number of eggs produced from 6 to 13 weeks of age in Japanese quail (Hassan et al., 2003).

Therefore, the experiment was aimed to study the effect of feed restriction on reproductive performance and egg production of Japanese quail, which would be very beneficial to poultry farmers in rural areas of Indonesian province and elsewhere.

MATERIALS AND METHODS

The experiment was conducted on State Polytechnic of Jember, East Java, Indonesia from April to June 2017. The sample was collected from 300 of Japanese quail hens at 2 weeks of age. Birds were housed with natural ventilation of 5 x 3 m² with laying cages of (40 x 20 x 15 cm³) at a density of 10 quail per cage. Quail hens were equally allotted to 2 dietary regimes, basic on EM R1= 2900 Kcal/kg; R2 = 2800 Kcal/kg and quantitative restricted feeding; P0 = 100% of ad libitum; P1 = 90% of ad libitum and P2 = 80% of (N = 300). Each group (n = 50) had five replicates containing 10 birds each.

All birds were reared under similar managerial and hygienic conditions. A starter diet containing 24% crude protein was fed from day-old to two weeks of age. Drinking...
water was provided via automatic nipple drinkers. Following 2 weeks on ad libitum feeding, all birds were fed according to treatment diets from 14 to 42 days of age and maintained until the first laid egg is seen. The composition of the experimental diet was given in Table 1.

Body weight and total feed intake data were determined on 14, 28, 35 and 42 days of age. Birds were maintained on assigned feeding regimens until first oviposition. Quails were individually weighed and mortality was recorded as occurred. Body weight, age at the first egg, first-egg weight, and development of reproductive organs were measured at sexual maturity. Initial egg production was recorded daily and egg weights (EW) were measured.

All of the data were studied by analysis of variance, including the effects of restricted feeding and EM content of the feed. When the F-test was significant, the least squares mean being compared. Initial egg production was recorded for two weeks period.

**RESULTS AND DISCUSSION**

**Reproductive Performance and Onset Sexual Maturity**

The effect of restricted feeding and EM of a ration on reproductive performance consisting of the average age of sexual maturity, the body weight of sexual maturity and first egg weight of quail hens are presented in Table 2. Restricted feeding on different EM ration indicated existence to delay of age at sexual maturity (p < 0.01). The delay was due to dietary restriction inhibiting growth rates including reproductive organs (Bunan, 1990). Sexual maturity of quail was postponed up to 8.8 days at a feeding rate of 80% with ME 2900 Kcal/kg, and 9.6 days at EM 2800 Kcal/kg. Age of sexual maturity at ad libitum feeding and restricted 90% of ad libitum did not show a significant difference (p > 0.05). The significant difference occurred in treatment P2 (80% of ad libitum). Wilson *et al.* (1983) suggested that the reduction of ration as much as 20% of the recommended amount of ration could slow down the reproductive organs.

Body weight at sexual maturity was not influenced by restricted feeding (p > 0.05). The weight of quail bodies with feeding ad libitum had the highest body weight of 187.67 g and the lowest at the feeding rate of 80% of 167.00 g. According to Hassan *et al.* (2003), the optimum weight at the adult age was 150 g, while the age of sexually adult was about 42 days. Delays in sexual maturity of adult genital quail with limited feed were due to the lack of optimal body weight. Brody *et al.* (1984) suggested that sexual maturity takes a certain weight and age to finalize on each strain of poultry. To achieve the weight of

*a,b,c*: means within same column with different superscripts (p < 0.05) are significantly different
optimal sex required high protein consumption. Other factors affecting genitalia are the lighting and cage system. Restricted feeding was able to increase the weight of the first egg laid ($p < 0.01$). The first group of quail eggs provided with limited feeding was significantly ($p < 0.05$) higher than the quail group with feeding $ad$ $libitum$. Although the increase in egg weight was possible, the increase was estimated due to the influence of individual variations. Immature body weight decreased the weight of eggs, mainly due to increased body weight during sex maturity (Summers and Lesson, 1983).

### Development of Reproductive Organs

The effect of restricted feeding and $EM$ of a ration on the development of the reproductive organ of quail are presented in Table 3. Restricted feeding on different $EM$ ration showed an increase of weight of the ovary ($p < 0.01$). The highest weight of ovary was on restricted $90\%$ $ad$ $libitum$. The length and weight of oviduct generally increased with increasing feed restriction. The decreasing of reproductive organs development was due to the slow growth of the reproductive organ (Hurwitz and Plavnik, 1989).

#### Table 3: The average of the development of reproductive organs on sexual maturity with restricted feeding

| ME ration (kcal/kg) | Restricted Feeding (% $Ad$-libitum) | Ovary weight (g) | Oviduct weight (g) | Oviduct Length (cm) |

### Egg Production, Egg Weight, and Egg Mass

The effect of restricted feeding and $EM$ of a ration on initial egg production are presented in Table 4. Egg production, expressed as laying percentage was insignificantly affected by diet restriction until $90\%$ of $ad$ $libitum$ feeding, both in $ME$ of ration. Restricted feeding until $80\%$ decreased egg production ($p < 0.05$). The average of initial egg production ranged from 32.97 to 38.81% and in this research, a diet containing 2900 Kcal $EM$/kg was satisfactory for Japanese quail hens for obtaining better egg production. These results were different than reported by Azeem and Azeem (2011). They found that $ME$ required for Japanese quail during the laying period was 2800 kcal $ME$/kg. The higher egg weight was shown by $80\%$ $ad$ $libitum$ feeding, but the converse trend, where quail fed $80\%$ $ad$ $libitum$ feeding and 2800 to 2900 Kcal $ME$ recorded similar values. This was in agreement with the reports of Summer et al. (1991) that restricted feeding birds had higher feed intake and egg weight than $ad$ $libitum$ feeding.

The results of the study indicated that $80\%$ feed restriction significantly ($p < 0.05$) improved feed conversion. The increase of egg weight due to $80\%$ $ad$ $libitum$ feeding was attributed to the age of quail which affected to a greater extent by the development of reproductive organs of quail.

#### Table 4: The Average of Initial Egg Production with Restricted Feeding

| EM ration (kcal/kg) | Restricted Feeding (% $Ad$-libitum) | Feed intake (g/hens) | Egg weight (g) | Hen Day Production (%) | Feed conversion |
|--------------------|--------------------------------------|----------------------|----------------|------------------------|----------------|
| 2900               | Ad $libitum$                         | 342.56a              | 9.28a          | 38.81a                 | 6.1$^a$        |

| SEM                | 10.9                                 | 0.138                | 0.957          | 0.140                  |
| $p$ value          | $<0.001$                             | 0.041                | $<0.001$       | 0.002                  |

$^a,b,c$: means within same column with different superscripts ($p < 0.05$) are significantly different
Conclusion
Restricted feeding until 80% of ad libitum delayed age at sexual maturity, decreased the development of reproductive organs and egg production. However, it improved feed conversion value, and no effect was found on body weight during the onset of sexual maturity. Restricted feeding at 90% of ad libitum and EM ration 2900 Kcal/kg showed the best results for quail feed management during growth.
