Wigner and Serber symmetries for the two-nucleon system provide unique examples of long distance symmetries in Nuclear Physics, i.e. symmetries of the meson exchange forces broken only at arbitrarily small distances. We analyze the large $N_c$ picture as a key ingredient to understand these, so far accidental, symmetries from a more fundamental viewpoint. A set of sum rules for NN phase-shifts, NN potentials and coarse grained $V_{\text{lowk}}$ NN potentials can be derived showing Wigner SU(4) and Serber symmetries not to be fully compatible everywhere. The symmetry breaking pattern found from the partial wave analysis data, high quality potentials in coordinate space at long distances and their $V_{\text{lowk}}$ relatives is analyzed on the light of large $N_c$ contracted SU(4)$_C$ symmetry. Our results suggest using large $N_c$ potentials as long distance ones for the two-nucleon system where the meson exchange potential picture is justified and known to be consistent with large $N_c$ counting rules. We also show that potentials based on chiral expansions do not embody the Wigner and Serber symmetries nor do they scale properly with $N_c$. We implement the One Boson Exchange potential realization saturated with their leading $N_c$ contributions due to $\pi, \sigma, \rho$ and $\omega$ mesons. The short distance $1/r^{3}$ singularities stemming from the tensor force can be handled by renormalization of the Schrödinger equation. A good description of deuteron properties and deuteron electromagnetic form factors in the impulse approximation for realistic values of the meson-nucleon couplings is achieved.

International Workshop on Effective Field Theories: from the pion to the upsilon
2-6 February 2009
Valencia, Spain

∗Speaker.

1. Introduction

The standard point of view in Particle Physics has often been that increasing the energy implies a higher degree of symmetry. In QCD, for instance, scale invariance roughly sets in for momenta much higher than the quark masses. In Nuclear Physics the situation may be exactly the opposite; some symmetries such as those introduced by Wigner \[1\] and Serber \[1\] are unveiled at low energies where the wavelength becomes larger than a certain scale. For obvious reasons we call them Long Distance Symmetries (LDS) \[3, 4\]. In the meson exchange picture this implies the presence of arbitrarily large symmetry breaking counterterms. We analyze these, so far accidental, LDS in the two-nucleon system below pion production threshold corresponding to CM momenta \(p \leq 400\text{MeV}\).

2. Wigner symmetry

The Wigner SU(4) spin-flavour symmetry corresponds to the algebra of isospin \(T^a\), spin \(S^i\) and Gamow-Teller \(G^ia\) generators in terms of the one particle spin \(\sigma^i_A\) and isospin \(\tau^a_A\) Pauli matrices,

\[
T^a = \frac{1}{2} \sum_A \tau^a_A, \quad S^i = \frac{1}{2} \sum_A \sigma^i_A, \quad G^{ia} = \frac{1}{2} \sum_A \sigma^i_A \tau^a_A. \tag{2.1}
\]

The two-body Casimir operator is \(C_{SU(4)} = T^a T_a + S^i S_i + G^{ia} G_{ia}\). The one-nucleon irreducible representations is a quartet made of a spin and isospin doublet

\[
\mathbf{4} = (p \uparrow, p \downarrow, n \uparrow, n \downarrow) = (S = 1/2, T = 1/2).
\]

Two nucleon states with relative angular momentum \(L\) and total spin \(S\) and isospin \(T\) fulfilling \((-1)^{S+L+T} = -1\) due to Fermi statistics correspond to an antisymmetric sextet and a symmetric decuplet which, in terms of \((S, T)\) representations of the \(SU_5(2) \otimes SU_7(2)\) subgroup, are

\[
\mathbf{6}_A = (1, 0) \oplus (1, 0) \quad L = 0, 2, \ldots \quad \rightarrow \left( ^1S_0, ^3S_1 \right), \left( ^1D_2, ^3D_{1,2,3} \right), \left( ^1G_2, ^3G_{1,2,3} \right), \ldots \tag{2.2}
\]

\[
\mathbf{10}_S = (0, 0) \oplus (1, 1) \quad L = 1, 3, \ldots \quad \rightarrow \left( ^1P_1, ^3P_{0,1,2} \right), \left( ^1F_1, ^3F_{0,1,2} \right), \ldots \tag{2.3}
\]

In particular, one obtains \(V_S_{J_1}(r) = V_{S_0}(r)\) which seems verified for \(r > 2\text{fm}\) (see Fig. 1 (left)) for high quality potentials \[3\], i.e. having \(\chi^2/\text{DOF} < 1\) for 6000 data \!. However, one might think that since a symmetry of the potential implies a symmetry of the S-matrix one should also have \(\delta_{S_0}(p) = \delta_{S_1}(p)\) at low energies, in total contradiction to the data in Fig. 1 (see Sect. 3).

3. Serber symmetry

A vivid demonstration of Serber symmetry is demonstrated in Fig. 2 (left) where the pn differential cross section at low CM momenta, \(p \leq 250\text{MeV}\), fulfills to a good approximation

\[
\frac{d\sigma_{pn}}{d\Omega} = |f_{pn}(\pi - \theta)|^2 = |f_{pn}(\theta)|^2, \quad \tag{3.1}
\]

suggesting no interaction in odd \(L\)-waves as \(P_L(\theta) = (-)^L P_L(\pi - \theta)\), a fact verified by NN potentials in the spin-triplet states for \(r > 1.2\text{fm}\), see Fig. 2 (middle) for the P-wave case. This assumption

\footnote{\text{There is no reference. According to R. Serber \[4\] the name "Serber force" was coined by E. Wigner around 1947.}}
can also be tested by looking at Deuteron photodisintegration, $\gamma d \to pn$, dominated above threshold by the $E_1$ transition $^3S_1 \to ^3P$. Neglecting tensor force and meson exchange currents (MEC) the cross section for a normalized deuteron state $u_d(r)$ with binding energy $B_d$ reads [8]

$$\sigma_{E1}(\gamma d \to pn) = \frac{\alpha \pi}{3p} \left| \langle p^2 + 2\mu_{pm}B_d \rangle \right| \left| \int_0^\infty dr u_d(r) r u_p(r) \right|^2$$

(3.2)

with $E_\gamma = B_d + p^2/(2\mu_{pm})$. For a free spherical P-wave $u_p(r) = pr j_1(pr)$, the agreement is good using $u_d(r)$ from effective range (ER) theory [6] or from a potential [3] (POT), see Fig. 2 (right).

A further hint for Serber symmetry comes from the late 50’s Skyrme proposal [7] to introduce a pseudopotential representing the NN effective interaction in nuclei in the form

$$V_{\text{effective}}(p', p) = t_0(1 + x_0 P_\sigma) + t_1(1 + x_1 P_\sigma)(p'^2 + p^2) + t_2(1 + x_2 P_\sigma) p' \cdot p + \ldots$$

(3.3)

with $P_\sigma = (1 + \sigma_1 \cdot \sigma_2)/2$ the spin exchange operator. $P_\sigma = -1$ for spin singlet $S = 0$ and $P_\sigma = 1$ for spin triplet $S = 1$ states. Serber symmetry corresponds to take $x_2 = -1$ in the P-wave term, $p' \cdot p$. Mean field theory calculations fitting single nucleon states yield $x_2 = -0.99$ [8].
4. Renormalization and Long Distance Symmetry

In the meson exchange picture \([9]\) the NN interaction can be decomposed as the sum

\[ V(x) = V_{\text{short}}(x) + V_{\text{long}}(x) \]

where the short range and scheme dependent piece is given by distributional contact terms

\[ V_{\text{short}}(r) = C_0 \delta(x) + C_2 \{ \nabla^2 \delta(x) \} + \ldots , \]

whereas the long distance piece \(V_{\text{long}}(x)\) is scheme independent and usually produces power divergences \(\sim 1/r^n\) at short distances. We introduce a short distance cut-off, \(r_c\), which will be removed in the end \(^2\). LDS means that even if \(V_{I,S_0}(r) = V_{I,S_1}(r)\) for any \(r > r_c\) one has \(C_{0,1,S_0} \neq C_{0,1,S_1}\). We analyze the implications by looking at finite energy \(S\)-wave scattering states

\[ u_p(r) = u_{p,c}(r) + p \cot \delta_0(p) u_{p,s}(r) \to \cos(pr) + \cot \delta_0(p) \sin(pr) , \]

where \(p = \sqrt{2\mu_pE}\) is CM momentum. For \(p \to 0\) then \(\delta_0(p) \to -\alpha_0 p\) and zero energy states are

\[ u_0(r) = u_{0,c}(r) - u_{0,s}(r)/\alpha_0 \to 1 - r/\alpha_0 \, , \]

Here \(u_{p,c}(r), u_{p,s}(r), u_{0,c}(r)\) and \(u_{0,s}(r)\) depend on \(V(r)\) only. Orthogonality in \(r_c \leq r < \infty\) requires

\[ 0 = \int_{r_c}^{\infty} dr \left[ u_{0,c}(r) - \frac{1}{\alpha_0} u_{0,s}(r) \right] \left[ u_{p,c}(r) + p \cot \delta_0(p) u_{p,s}(r) \right] . \]

Note that the potential \(V(r)\) and the scattering length \(\alpha_0\) are independent variables. Thus we assume Wigner symmetry for the potential \(V_{I,S_0}(r) = V_{I,S_1}(r)\) but experimentally different scattering lengths \(\alpha_{S_0} = -23.74\text{fm}\) and \(\alpha_{S_1} = 5.42\text{fm}\), yielding from Eq. \((4.5)\) the structure for \(r_c \to 0\)

\[ p \cot \delta_{S_0}(p) = \frac{\alpha_{S_0} \mathscr{A}(p) + \mathscr{B}(p)}{\alpha_{S_0} \mathscr{C}(p) + \mathscr{D}(p)} \, , \quad p \cot \delta_{S_1}(p) = \frac{\alpha_{S_1} \mathscr{A}(p) + \mathscr{B}(p)}{\alpha_{S_1} \mathscr{C}(p) + \mathscr{D}(p)} \, , \]

showing that a symmetry of the potential for any \(r > r_c, r_c \to 0\), is not necessarily a symmetry of the S-matrix. The result for \(\pi + \sigma\) exchange, while not exact, works rather well (see Fig. \([3]\)).

5. Sum rules

Based on the LDS idea we have recently derived the sum rules for phase shifts \([3, 4]\)

\[ \begin{array}{ccl}
\delta_{L}(p) = \delta_{L}(p) & \text{Wigner} & \text{all } L \\
\delta_{L}(p), \delta_{L}(p) = 0 & \text{Serber} & \text{odd } L \end{array} \]

where we have defined the multiplet center \(\delta_{L}^{ST} = 1/(3(2L + 1)) \sum_{J=L-1}^{L+1} (2J + 1) \delta_{L,J}^{ST}\). From data Fig. \([3]\) shows that one has Wigner for \textit{even} \(L\) and Serber for \textit{triplet odd} \(L\). The LDS character accommodates the symmetry for increasing \(p\) and \(L\); what matters is the impact parameter, \(b \sim L/p\).

The previous sum rules have a parallel long distance potential analog, and are also well verified for \(r > 1.5\text{fm} [4]\). This suggests that a coarse graining of the interaction using e.g. the \(V_{\text{lowk}}\) potentials \([1]\) works and justifies \textit{per se} the symmetry obtained phenomenologically by fitting single particle states \([8]\) for the Skyrme effective force, Eq. \((3.3), [4]\). We find that \(V_{I,L,\text{lowk}}(p,p) \ll V_{I,L,\text{lowk}}(p,p)\) for \((-1)^L = -1\) and \(V_{I,L,\text{lowk}}(p,p) \sim V_{I,L,\text{lowk}}(p,p)\) for \((-1)^L = 1\).

\(^2\)The constants \(C_0, C_2\) etc. are scale dependent. The equivalence with momentum space renormalization is shown in Ref. \([1]\) where the limit \(r_c \to 0\) implies the irrelevance of \(C_2\) in the presence of a singular chiral potential.
Serber symmetry is possible but less evident (see [4]). This suggests to use large its contracted spin-flavour group. Thus, large nucleon-nucleon potentials

As it is well known, in the large \( N_c \) limit with \( \alpha_s N_c \) fixed, nucleons are heavy, \( M_N \sim N_c \) [13], and the NN potential \( \sim N_c \) becomes meaningful. The amazing aspect is that the symmetry pattern of the sum rules for the old nuclear Wigner and Serber symmetries largely complies to the large \( N_c \) and QCD based contracted \( SU(4)_C \) symmetry [13, 14] where the tensorial spin-flavour structure is

\[
V(r) = V_C(r) + \tau_1 \cdot \tau_2 [\sigma_1 \cdot \sigma_2 W_S(r) + S_{12} W_T(r)] \sim N_c
\]

Other operators are \( O(N_c^{-1}) \) and hence suppressed by a relative \( 1/N_c^2 \) factor. One has the sum rules

\[
\begin{align*}
V_{1L}(r) &= V_{1L}(r) = V_C(r) - 3W_S(r) + O(N_c^{-1}), \quad (−1)^L = +1 \\
V_{1L}(r) &= V_C(r) + 9W_S(r) + O(N_c^{-1}), \quad (−1)^L = −1 \\
V_{1L}(r) &= V_C(r) + W_S(r) + O(N_c^{-1}), \quad (−1)^L = −1
\end{align*}
\]

Thus, large \( N_c \) implies Wigner symmetry only in even-L channels, exactly as observed in Fig. 3. Serber symmetry is possible but less evident (see [4]). This suggests to use large \( N_c \) itself and its contracted spin-flavour group \( SU(4)_C \) as a long distance symmetry. Actually, the energy independent potential may be obtained in a multi-meson exchange picture consistently with large \( N_c \) counting rules [15]. Retaining one boson exchange (OBE) with \( \pi, \sigma, \rho \) and \( \omega \) mesons one has

\[
\begin{align*}
V_C(r) &= -\frac{g_{\pi NN}^2 e^{-m_\pi r}}{4\pi} + \frac{g_{\sigma NN}^2 e^{-m_\sigma r}}{4\pi}, \\
W_S(r) &= \frac{g_{\pi NN}^2 m_\pi^2 e^{-m_\pi r}}{48\pi \Lambda_N^2} + \frac{f_{\rho NN}^2 m_\rho^2 e^{-m_\rho r}}{24\pi \Lambda_N^2}, \\
W_T(r) &= \frac{g_{\pi NN}^2 m_\pi^2 e^{-m_\pi r}}{48\pi \Lambda_N^2} \left[ 1 + \frac{3}{m_\pi r} + \frac{3}{(m_\pi r)^2} \right] - \frac{f_{\rho NN}^2 m_\rho^2 e^{-m_\rho r}}{48\pi \Lambda_N^2} \left[ 1 + \frac{3}{m_\rho r} + \frac{3}{(m_\rho r)^2} \right]
\end{align*}
\]

where \( \Lambda_N = 3M_p/N_c \) and \( g_{\pi NN}, g_{\sigma NN}, f_{\rho NN}, g_{\omega NN} \sim \sqrt{N_c} \) and \( m_\pi, m_\sigma, m_\rho, m_\omega \sim N_0 \). To leading and subleading order in \( N_c \) one may neglect spin orbit, meson widths and relativity. The tensor force \( W_T \) is singular at short distances \( \sim 1/r^3 \) and requires renormalization (see [17] for the \( \pi \) case).

\( ^3 \)The LDS character implies relaxing the contact interaction piece not to be of the same form as the long distance potentials, i.e. \( V_{\text{short}}(\vec{x}) \neq (C_C + \tau_1 \cdot \tau_2 [\sigma_1 \cdot \sigma_2 C_S + S_{12} C_T]) \delta(\vec{x}) \) avoiding the extra symmetry, \( \tau_2 \sigma_1 \rightarrow -\tau_2 \sigma_1 \) [16].
Table 1: Deuteron properties for renormalized large \( N_c \) OBE potentials. We use \( \gamma = \sqrt{2\mu_\rho B_d} \) with \( B_d = 2.224575(9) \) and take \( g_{\pi NN} = 13.1083, m_\pi = 138.03 \text{MeV}, m_\rho = 770 \text{MeV}, m_\omega = 782 \text{MeV} \). A fit to the \(^1S_0\) phase shift gives \( m_\sigma = 501 \text{MeV} \) and \( g_{\sigma NN} = 9.1 \). \( \pi \sigma \rho \omega \) uses \( f_{pNN} = 15.5 \) and \( g_{\omega NN} = 9.857 \) while \( \pi \sigma \rho \omega^* \) uses \( f_{pNN} = 17.0 \) and \( g_{\omega NN} = 10.147 \). Experimental or recommended values from Ref. [19].

| \( \pi([7]) \) | Input | \( \gamma(\text{fm}^{-1}) \) | \( \eta \) | \( A_S(\text{fm}^{-1/2}) \) | \( r_m(\text{fm}) \) | \( Q_d(\text{fm}^2) \) | \( P_D \) | \( \langle r^1 \rangle \) |
|----------------|------|----------------|---|----------------|---|-------------|---|-------------|
| \( \pi \sigma \) | Input | 0.02633 | 0.8681 | 1.9351 | 0.2762 | 7.88% | 0.476 |
| \( \pi \sigma \rho \omega \) | Input | 0.02597 | 0.9054 | 2.0098 | 0.2910 | 6.23% | 0.432 |
| \( \pi \sigma \rho \omega^* \) | Input | 0.02625 | 0.8902 | 1.9773 | 0.2819 | 7.22% | 0.491 |
| Nijm93([5]) | Input | 0.02521 | 0.8845(8) | 1.9659 | 0.2821 | 9.09% | 0.497 |
| Test ([19]) | Input | 0.02514 | 0.8845(8) | 1.9686 | 0.2703 | 5.635% | 0.4502 |

Deuteron properties are shown in Table 1 for parameters always reproducing the \(^1S_0\) phase shift, Fig. 1 (middle). Space-like electromagnetic form factors in the impulse approximation [20] for \( G_E^0(\mathbf{q}^2) = 1/(1 + \mathbf{q}^2/m_\rho^2) \) and without MEC are plotted in Fig. 4 (see [21] for the \( \pi \) case). Overall, the agreement is good for realistic couplings.

For large \( N_c \), the central potential is leading, Eq. (6.5). Energy independent potentials using power counting within Chiral Perturbation Theory (ChPT) [22] yield a central force \( V_{\text{ChPT}}^C \) only to \( O(1/f_{\pi}^4 M_N) \) i.e. \( N^2\text{LO} \) and ChPT potentials do not scale properly with \( N_c \) since \( g_A \sim N_c, f_\pi \sim \sqrt{N_c} \) and there are terms scaling as \( V_{\text{ChPT}}^C \sim g_A^2/f_{\pi}^2 \sim N_c^2 \) and not as \( \sim N_c \), even after inclusion of \( \Delta [23] \). Moreover, Wigner and Serber symmetries are violated at long distances since

\[
V_{\text{ChPT}}^C(r) = (1 + 2\tau_1 \cdot \tau_2) e^{-m_\sigma r} \frac{r^2}{r^2} + \cdots
\]

(6.8)

These features might perhaps explain why renormalizing ChPT potentials in different schemes a mismatch of \( 10^6 \) at \( p = 400 \text{MeV} \) for the \(^1S_0\) phase shift is persistently obtained [24, 25].

7. Conclusions

Wigner and Serber symmetries in the NN system are realized as long distance ones and are largely compatible with the large \( N_c \) picture. When large \( N_c \) NN-potentials are saturated by \( \pi, \sigma, \rho \) and \( \omega \) exchange and subsequently renormalized, we obtain satisfactory results for the deuteron and central partial waves. This suggests that large \( N_c \) potentials might eventually provide a workable scheme, less directly related to ChPT but closer in spirit to the common wisdom of Nuclear Physics.

---

4The Goldberger-Treiman relation gives \( g_{\pi NN} = g_{\pi MN}/f_\pi = 12.8 \) for pions and \( g_{\sigma NN} = M_N/f_\pi = 10.1 \) for scalars for \( f_\pi = 92.3 \text{MeV} \) and \( g_A = 1.26 \). Sakurai’s universality and KSF yield \( g_{\sigma NN} = g_{\sigma NN}/2 = m_\rho/f_\pi/\sqrt{2} = 2.9 \). From \( SU(3) \) we have \( g_{\sigma NN} = 3g_{\rho NN} - g_{\sigma NN} = 8.7 \) using OZI rule, \( g_{\rho NN} = 0 \). \( \rho - \text{meson dominance yields} \ f_{pNN} = \kappa_\rho g_{\rho NN} \) with \( \kappa_\rho = \mu_\rho - \mu_\pi - 1 = 3.7 \) with \( \mu_\rho = 2.79 \) and \( \mu_\pi = -1.91 \). Adding \( \rho^1, \rho^2 \) states yields \( \kappa_\rho = 6.1 \) and thus \( f_{\rho NN} = 18 \).
