Edited by Anthony A. James, University of California, Irvine, CA, and approved March 16, 2018 (received for review January 12, 2018)

*Wolbachia* are maternally inherited, intracellular bacteria at the forefront of vector control efforts to curb arbovirus transmission. In international field trials, the cytoplasmic incompatibility (CI) drive system of *wMel Wolbachia* is deployed to replace target vector populations, whereby a *Wolbachia*-induced modification of the sperm genome kills embryos. However, *Wolbachia* in the embryo rescue the sperm genome impairment, and therefore CI results in a strong fitness advantage for infected females that transmit the bacteria to offspring. The two genes responsible for the *wMel*-induced sperm modification of CI, *cifA* and *cifB*, were recently identified in the eukaryotic association module of prophage WO, but the genetic basis of rescue is unresolved. Here we use transgenic and cytological approaches to demonstrate that maternal *cifA* expression independently rescues CI and nullifies embryonic death caused by *wMel Wolbachia* in *Drosophila melanogaster*. Discovery of *cifA* as the rescue gene and previously one of two CI induction genes establishes a “Two-by-One” model that underpins the genetic basis of CI. Results highlight the central role of prophage WO in shaping *Wolbachia* phenotypes that are significant to arthropod evolution and vector control.

**cytoplasmic incompatibility | rescue | Wolbachia | prophage WO | Drosophila melanogaster**

The bacteria *Wolbachia* occur in an estimated 40–52% of arthropod species (1, 2) and 47% of the Onchocercidae family of filarial nematodes (3), making them the most widespread bacterial symbiont in the animal kingdom (2). In arthropods, *Wolbachia* mainly reside in the cells of the reproductive tissues, transmit transovarially (4), and often commandeer host fertility, sex ratios, and sex determination to enhance their maternal transmission via male killing, feminization, parthenogenesis, or cytoplasmic incompatibility (CI) (5, 6).

Discovered nearly half a century ago (7), *Wolbachia*-induced CI is the most common reproductive modification and results in embryonic lethality when an infected male mates with an uninfected female, but this lethality is rescued when the female is likewise infected (8). As such, rescue can provide a strong fitness advantage to infected females, the transmitting sex of *Wolbachia* (9–11). Alone, CI-induced lethality is deployed in vector control studies to crash the resident uninfected mosquito population through release of *Wolbachia*-infected males (12–17). Together, CI-induced lethality and rescue constitute a microbrial drive system that is used in field studies worldwide to stably replace an uninfected mosquito population with an infected one via release of males and females harboring *wMel Wolbachia* (18), which confer resistance against dengue and Zika viruses (19, 20). The efficacy of this drive system for spreading *Wolbachia* in target populations critically depends on *Wolbachia*’s ability to rescue its own lethal sperm modifications.

While CI is gaining momentum as a natural, sustainable, and inexpensive tool for vector control, the genes that underpin this microbial adaptation are not fully known. Our previous screen of *Wolbachia* genomes and transcriptomes from infected ovaries identified two adjacent genes, *cifA* and *cifB*, from the *wMel* strain in *Drosophila melanogaster* as the only genes strictly associated with CI (21). These two genes occur in the eukaryotic association module of prophage WO (22) and recapitulate CI when dually expressed in uninfected male flies (21, 23). Each gene alone is incapable of inducing CI (21), and the rescue gene remains unknown. As *cifA* and *cifB* are the only two *wMel* genes strictly associated with CI, we previously hypothesized that the CI induction and rescue genes might be the same (21). Here we test the hypothesis that transgenic expression of *cifA* and/or *cifB* genes from *wMel Wolbachia* in ovaries can rescue CI and nullify the associated embryonic defects in *D. melanogaster*.

**Results and Discussion**

Since *Wolbachia* cannot be genetically transformed, we tested the ability of *cifA* to transgenically rescue wild-type CI using a GAL4-UAS system for tissue-specific expression in uninfected *D. melanogaster* females. In transcriptomes of *wMel*-infected *D. melanogaster*, *cifA* is a highly expressed prophage WO gene (24). As such, we conducted the transgenic experiments under the control of either *nos-GAL4-tubulin* in uninfected germline stem cells or the maternal triple driver, MTD-GAL4, to drive higher transgene expression throughout oogenesis. MTD-GAL4 utilizes two *nos-GAL4* driver variants (including *nos-GAL4-tubulin*) and

**Significance**

The World Health Organization recommended pilot deployment of *Wolbachia*-infected mosquitoes to curb viral transmission to humans. Releases of mosquitoes are underway worldwide because *Wolbachia* can block replication of these pathogenic viruses and deterministically spread by a drive system termed cytoplasmic incompatibility (CI). Despite extensive research, the underlying genetic basis of CI remains only half-solved. We recently reported that two prophage WO genes recapitulate the modification component of CI in a released strain for vector control. Here we show that one of these genes underpins rescue of CI. Together, our results reveal the complete genetic basis of this selfish trait and pave the way for future studies exploring WO prophage genes as adjuncts or alternatives to current control efforts.

**Author contributions:** J.D.S. and S.R.B. designed research; J.D.S., J.O., E.M.L., and H.Z. performed research; S.R.B. contributed new reagents/analytic tools; J.D.S., J.O., and S.R.B. analyzed data; J.D.S. and S.R.B. wrote the paper; and J.O., E.M.L., and H.Z. provided feedback on the paper.

**Conflict of interest statement:** J.D.S. and S.R.B. are listed as inventors on a provisional patent relevant to this work. S.R.B. is a coinventor on two other pending patents related to controlling arthropods.

an ovarian tumor driver (25). Control CI and rescue crosses with either driver yielded the expected hatching rates. Crosses between infected males and uninfected females expressing cifA under the control of MTD-GAL4 showed a markedly significant increase in embryonic hatching relative to cifA expression under nos-GAL4-tubulin and at levels similar to that in control rescue crosses (Fig. L4). These results are consistent with complete rescue of CI by cifA, in association with increased expression throughout the developing egg chambers. Similar results with nos-GAL4-tubulin expression in unin- fected ovaries resulted in a small increase in hatch rate that was inconsistently significant among replicates (Fig. S1). An analysis of cifA gene expression revealed that MTD-GAL4 associates with a three-order-of-magnitude increase over nos-GAL4-tubulin, supporting strength of expression as a factor for rescue (Fig. 1B).

We expanded our evaluation of cif gene expression under the control of MTD-GAL4 in uninfected females to test if cifB alone or in combination with cifA impacts CI penetrance. As expected, infected males crossed to either uninfected females or females transgenically expressing cifB under MTD-GAL4 yielded similar CI penetrance (Fig. 2). These results suggest that cifB does not rescue CI when transgenically expressed in the ovaries, and its CI-related function is specific to testes. In contrast, MTD-GAL4 expression of cifA, by itself or in combination with cifB, significantly rescued CI to levels comparable to rescue by infected females (Fig. 2). These results are consistent with cifA independently functioning as the rescue factor and suggest that cifB does not inhibit cifA’s ability to rescue CI. As Wolbachia can induce phenotypes known to bias sex ratios, we collected the surviving offspring from the transgenic and control rescue crosses and sexed them to demonstrate normal sex ratios, indicating that rescue was not sex-specific (Fig. S2).

Next, we tested if the canonical cytological defects observed in early CI embryos [early mitotic failure, chromatin bridging, and regional mitotic failure (26)] were nullified under cifA-induced rescue. We examined embryos from control and transgenic crosses after 1–2 h of development and binned their cytology into one of five phenotypes as previously established for D. melanogaster CI (21). Nearly half of CI-induced lethality in embryos is the result of embryonic arrest during advanced developmental stages in Dipteran species (27–30). As expected, the control CI cross yielded high levels of all three CI-associated defects, and the embryos from the control rescue cross developed with significantly fewer abnormalities (Fig. 3). MTD-GAL4 transgenic expression of cifA in uninfected females, either alone or dually expressed with cifB, resulted in significantly fewer cytological defects (Fig. 3). These effects were not seen with transgenic cifB expression, again validating that cifA alone can recapitulate wild-type rescue by Wolbachia.

These data are in contrast with previous work reporting the inability to transgenically rescue CI in D. melanogaster (23); however, there are three critical differences between the studies. First, wPip’s homologs from Culex pipiens were used in the prior work instead of wMel’s cif genes from D. melanogaster here. Thus, differences in host background interactions could explain the discrepancy. Second, a T2A sequence between the wPip gene

---

**Fig. 1.** cifA rescues cytoplasmic incompatibility when it is highly expressed throughout oogenesis. (A) Hatch rate assays were conducted with transgenic expression of cifA under the control of nos-GAL4-tubulin or MTD-GAL4 drivers. Each dot represents a replicate. Rescue occurred only under MTD-GAL4 expression. Horizontal dotted lines from top to bottom separate cross-types with CI, cifA expression, and rescue. Wolbachia infections are represented by filled sex symbols, and expressed genes are noted to the right of the corresponding sex. n = 27–59 for each experimental cross across two experiments (both shown). Vertical bars represent medians, and letters to the right indicate significant differences based on α = 0.05 calculated by Kruskal–Wallis and Dunn’s test for multiple comparisons. (B) Gene expression fold change of cifA relative to the Drosophila housekeeping gene rp49 was determined on a subset of abdomens from females expressing cifA via MTD-GAL4 or nos-GAL4-tubulin with 2−ΔΔCt. Horizontal bars represent medians with 95% confidence intervals, and letters above indicate significance based on a Mann–Whitney U test. In both cases, statistical comparisons are between all groups. Exact P values are provided in Table S2. Hatch rate experiments testing expression of cifA under MTD-GAL4 or nos-GAL4-tubulin have been repeated four and five times, respectively.

**Fig. 2.** Rescue of cytoplasmic incompatibility is specific to cifA. Hatch rate assays were conducted with transgenic expression of cifA, cifB, and cifA:B using the MTD-GAL4 driver for expression throughout oogenesis. Each dot represents a replicate. Wolbachia infections are represented by filled sex symbols, and expressed genes are noted to the right of the corresponding sex. n = 11–29 for each experimental cross. Vertical bars represent medians, and letters to the right indicate significant differences based on α = 0.05 calculated by Kruskal–Wallis and Dunn’s test for multiple comparisons. Statistical comparisons are between all groups. Exact P values are provided in Table S2. Hatch rate experiments testing expression of cifA under MTD-GAL4 have been repeated four times.
This modification-rescue model posits that each strain of *Wolbachia* has its own set of *cifA*- and *cifB*-associated CI modifications and one *cifA* rescue factor. The different roles of *cifA* and *cifB* are intriguing. We predict that the function of *cifA* is dependent on differential localization and/or modification of gene products in testes/sperm (CI) relative to ovaries/embryos (rescue). Moreover, one could speculate that the putative anti-oxidant catalase-rel domain of the *CifA* protein acts as a functional switch in response to reactive oxygen species, known to be higher in *Wolbachia*-infected testes (34), whereas the Puf-family RNA binding domain and STE are involved in RNA binding and transcriptional (mis)regulation of an unknown host factor.

It has been hypothesized that divergence in modification and rescue genes leads to bidirectional CI (21, 35, 36), which is a reciprocal incompatibility between males and females infected with different *Wolbachia* strains (7, 37–40). Comparative genomic analyses of *cifA* and *cifB* genes reveal extremely high levels of amino acid divergence (21), strong codivergence (21, 33), and recombination (36), consistent with the very rapid evolution of bidirectional CI across *Wolbachia* that can contribute to reproductive isolation and speciation (40, 41). Indeed, divergence of the *cifA* and *cifB* genes into several phylogenetic types correlates with bidirectional CI patterns in *Drosophila* and *Culex* (21, 36). There are at least two explanations for how simple genetic changes in these genes can contribute to bidirectional CI. First, a single mutation in the *cif* gene could produce variation in the modification and rescue components that render two *Wolbachia* strains incompatible. For instance, given an ancestral and derived allele of *cifA*, males and females with *Wolbachia* carrying the same *cifA* allele are compatible; however, males with *Wolbachia* carrying the ancestral *cifA* allele cause a sperm modification that is unable to be rescued by embryos with *Wolbachia* carrying the derived *cifA* allele, and vice versa. Thus, a single mutation in *cifA* alone can enable the switch from being compatible to incompatible *Wolbachia*. Second, mutations in both *cifA* and *cifB* could be required for the evolution of bidirectional CI. For example, CifA-CifB protein binding (23) and/or differential localization in the sperm and egg may underpin bidirectional CI between *Wolbachia* strains. In this model, amino acid divergence in the homologs was used to allow for bicistronic expression, but ribosome skipping results in a C-terminal sequence extension to the first protein and a proline addition to the second protein that generates sequence artifacts and could alter function (31). Finally, different insertion sites are capable of different levels of expression due to their local chromatin environment (32), thus the chosen sites may produce insufficient product to cause rescue.

*cifA* encodes a putative catalase-rel domain, a sterile-like transcription factor (STE) domain, and a domain of unknown function (DUF3243) that shares homology with a putative Puf-family RNA binding domain in *cifA*-like homologs (33), whereas *cifB* has nuclease and deubiquitilase domains (23, 33). Only the deubiquitilase annotation has been functionally tested and confirmed (23). Based on subcellular localization (PSORTb) and transmembrane helix predictors (TMbase), CifA is a cytoplasmic protein without transmembrane helices (Fig. S3). Codon-based and Fisher’s exact tests of neutrality demonstrate that closely related (76.2–99.8% pairwise nucleotide identity) type 1 *cifA* homologs (21) largely evolve by purifying selection (Fig. S4 *A* and *B*), and sliding window analyses [sliding window analysis of *K*<sub>s</sub> and *K*<sub>s</sub>/K<sub>a</sub> (SWAKK) and Java codon delimited alignment, JCoDA] reveal that purifying selection is strongest on the catalase-rel domain and the unannotated region at the N terminus, with considerably weaker purifying selection on the putative DUF3243 and STE domains (Fig. 4 and Fig. S4C). This is supported by prior work reporting stronger amino acid conservation within the type 1 CifA N terminus relative to the C terminus (33).

These findings illustrate that the *Wolbachia* prophage WQ gene *cifA* recapitulates rescue of wild-type CI. As *cifA* is one of two genes involved in induction of CI, results support the hypothesis that a gene involved in CI induction is also the rescue gene (21). In addition, transgenic expression of *cifA* in yeast inhibits a temperature-dependent growth defect caused by *cifB* expression (23). The discovery that CI is induced by *cifA* and *cifB* and rescued by *cifA* motivates a Two-by-One model of CI where two genes act as the CI modification factors (in the male), and one of these same genes acts as the rescue factor (in the female).
Cif proteins may contribute to weakened binding, which in turn yields Wolbachia strains incapable of CI but capable of rescuing CI by the ancestral variant (42, 43). A compensatory substitution in the other Cif protein could in theory restore binding and yield bidirectional incompatibility with the ancestral Cif variants. Codivergence between amino acid sequences of these proteins is consistent with this model. Under both models, the presence of multiple WO prophages carrying cifA genes may also promote incompatibilities through the production of multiple CI product complexes simultaneously (21). In support of these hypotheses, complex diversification and duplication of cifA and cifB have been reported in Droso-
hila and C. pipiens that harbor a variety of incompatible Wolbachia strains (21, 36).

In conclusion, our findings reveal the connected genetic basis of CI and rescue and highlight the fundamental impact of prophage WO genes on the adaptive phenotypes of an obligate intracellular bacteria. In addition to genetically dissecting this widespread form of reproductive parasitism and microbial drive, we also establish a Two-by-One model to explain the modifica-
tion and rescue components of CI. Finally, beneficial applica-
tions of CI and rescue genes as transgenic drive constructs may be possible as adjuncts or alternatives to pest control or vector control strategies currently employing Wolbachia-infected mos-
quitos (15–18).

Materials and Methods

Fly Rearing and Strains. D. melanogaster stocks y w (BDSC 1495), nos-GALA-
tubulin (BDSC 4442), MTD-GAL4 containing nos-GALA-tubulin, nos-GALA-VP16, and ntu-GAL4-VP16 (BDSC 31777), and UAS transgenic lines homozygous for cifA, cifB, and cifA/B (21) were maintained at 12:12 light:dark at 25 °C and 70% relative humidity (RH) on 50 mL of a standard media. GAL4 lines were found to be infected with wMel Wolbachia, and uninfected lines were produced through tetracycline treatment as previously described (21). Infection status was frequently confirmed via PCR using WolbF and WolbR3 primers (44) (Fig. S5).

During virgin collections, flies were stored at 18 °C overnight to slow eclosion rate, and virgin flies were kept at room temperature.

Hatch Rate and Sex Ratio Assays. Virgin MTD-GAL4 females were collected for the first 3 d of emergence and aged 9–11 d before crossing to nonvirgin homozygous UAS (cifA, cifB, or cifA/B) males. The start of collections for the maternal and paternal lineages was staggered by 7 d. Single pair matings occurred in 8-oz bottles, and a grape-juice agar plate was smeared with yeast and affixed to the opening of each bottle with tape. The flies and bottles were then stored at 25 °C and 70% RH for 24 h, at which time the plates were replaced with freshly smeared plates and again stored for 24 h. Plates were then removed and the number of embryos on each plate were counted and stored. After 30 h the remaining unhatched embryos were counted (Fig. S6).

The hatch rate was calculated by dividing the number of hatched embryos by the initial embryo count and multiplying by 100. Hatch rate was plotted against clutch size for 3 MTD-GAL4 and 4 nos-GALA-tubulin rescue crosses conducted in this study to reveal a significant correlation (Fig. S5), and a threshold clutch size for analysis was set equal to exclusion of 99% of plates with a hatch rate of 0 for each genotype (31 for nos-GALA-tubulin and 48 for MTD-GAL4). Larvae were moved into vials of standard media and the offspring sex ratio determined after 15–18 d (Fig. S6).

Hatch rates testing MTD-GAL4 or nos-GALA-tubulin expression of cifA were conducted four and five times, respectively. Sex ratio experiments were conducted once.

Gene Expression. To compare the level of UAS-cifA expression between MTD-
GAL4 and nos-GALA-tubulin flies, mothers from hatch rate assays were col-
lected after the allotted laying period, abdomens were immediately dissected, and samples were frozen in liquid nitrogen and stored at −80 °C until processing. RNA was extracted using the Direct-zol RNA MiniPrep Kit (Zymo), DNase treated with DNA-free (Ambion, Life Technologies), and cDNA was generated with Superscript VILO (Invitrogen). Quantitative PCR was performed on a Bio-Rad CFX-96 Real-Time System using iTaq Universal SYBR Green Supermix (Bio-Rad). Forty cycles of PCR were performed against positive controls (extracted DNA), negative controls (water), no RT control (RNA), and cDNA with the following conditions: 50 °C 10 min, 95 °C 5 min, 40x (95 °C 10 s, 55 °C 30 s), 95 °C 30 s. Primers used were cifA opt and rp49 forward and reverse (Table S1). Fold expression of UAS-cifA relative to the D. melanogaster housekeeping gene rp49 was determined with 2ΔΔCt.

This experiment and corresponding hatch rate were performed once.

Embryo Cytology. Flies were collected as described for the hatch rate assays, but with 60 females and 12 males in each bottle with a grape-juice agar plate attached. All flies used were siblings of those from the hatch rate, grape-
juice plates replaced as described above, and embryos collected in parallel to egg laying by hatch rate females. Embryos were collected, dechorio-
nated, washed, methanol fixed, stained with propidium iodide, imaged, and categorized as previously described (21) (Fig. S6). This experiment was performed once.

Putative CifA Localization. The PSORTb v3.0.2 web server (45) was used to predict subcellular localization of the wMel CifA protein to either the cytoplasm, cytoplasmic membrane, periplasm, outer membrane, or extracellular space. A localization score is provided for each location, with scores of 7.5 or greater considered probable localizations. The TMPred web server (46) was used to predict transmembrane helices in wMel CifA. TMPred scores were generated for transmembrane helices spanning from inside-to-outside (i-o) and outside-to-inside (o-i), and scores above 500 are considered significant.

cifA Selection Analyses. Selection analyses were conducted using four in-
dependent tests of selection: codon-based Z test of neutrality (47), Fisher’s exact test of neutrality (47), Sliding window analysis of Ks and Ks’ (SWAKK) (48), and Java Codon Delimitated Alignment (JCoDA) (49). The first two analyses were conducted using the MEGA6 desktop app with a MUSCLE translation alignment generated in Geneious v5.5.9. The SWAKK 2.1 web server and the JCoDa v1.4 desktop app were used to analyze divergence between wMel and wHa CifA with a sliding window of 25 codons and a jump size of 1 codon for SWAKK and 5 codons for JCoDa.

Statistical Analyses. All statistical analyses were conducted in GraphPad Prism (GraphPad Prism 7 or online tools). Hatch rate and sex ratio statistical comparisons were made using Kruskal–Wallis followed by Dunn’s multiple comparison test.

Expression was compared using a Mann–Whitney U test. Correlations be-
tween hatch rate and clutch size were determined using Spearman rho. Pairwise χ2 analyses were used for cytology studies to compare defective and normal embryos followed by generation of Bonferroni adjusted P values.

An unpaired t test was used for statistical comparison of RNA fold expression. All P values are reported in Table S2.

Data Availability. All source data and replicate data are available as Sup-
porting Information along with this publication.

ACKNOWLEDGMENTS. We thank Daniel LePage for preliminary work, Sarah R. Bordenstein and Jessamyn Perlmutter for manuscript preparation, and Jared Nordman for kindly providing the MTD-GAL4 line.
