Tightening QC Relaxations of AC Optimal Power Flow Problems via Complex Per Unit Normalization

Mohammad Rasoul Narimani, Member, IEEE, Daniel K. Molzahn, Senior Member, IEEE, and Mariesa L. Crow, Fellow, IEEE

Abstract—Optimal power flow (OPF) is a key problem in power system operations. OPF problems that use the nonlinear AC power flow equations to accurately model the network physics have inherent challenges associated with non-convexity. To address these challenges, recent research has applied various convex relaxation approaches to OPF problems. The QC relaxation is a promising approach that convexifies the trigonometric and product terms in the OPF problem by enclosing these terms in convex envelopes. The accuracy of the QC relaxation strongly depends on the tightness of these envelopes. This paper presents two improvements to these envelopes. The first improvement leverages a polar representation of the branch admittances in addition to the rectangular representation used previously. The second improvement is based on a coordinate transformation via a complex per unit base power normalization that rotates the power flow equations. The trigonometric envelopes resulting from this rotation can be tighter than the corresponding envelopes in previous QC relaxation formulations. Using an empirical analysis with a variety of test cases, this paper suggests an appropriate value for the angle of the complex base power. Comparing the results with a state-of-the-art QC formulation reveals the advantages of the proposed improvements.

Index Terms—Optimal power flow, Convex relaxation.

I. INTRODUCTION

Optimal power flow (OPF) problems are central to many tasks in power system operations. OPF problems optimize an objective function, such as generation cost, subject to both the network physics and engineering limits. The AC power flow equations introduce non-convexities in OPF problems. Due to these non-convexities, OPF problems may have multiple local optima [1], [2] and are generally NP-Hard [3].

Many research efforts have focused on algorithms for obtaining locally optimal or approximate OPF solutions [4]. Recent research has also developed convex relaxations of OPF problems [5]. Convex relaxations bound the optimal objective values, can certify infeasibility, and, in some cases, provably provide globally optimal solutions to OPF problems.

The capabilities of convex relaxations are, in many ways, complementary to those of local solution algorithms. For instance, relaxations’ objective value bounds can certify how close a local solution is to being globally optimal. Accordingly, local algorithms and relaxations are used together in spatial branch-and-bound methods [6]. Solutions from relaxations are also useful for initializing some local solvers [7]. Relaxations are also needed for certain solution algorithms for robust OPF problems [8]. Moreover, the objective value bounds provided by relaxations are directly useful in other contexts, e.g., [9], [10]. The tractability and accuracy of these and other algorithms are largely determined by the employed relaxation’s tightness. Tightening relaxations is thus an active research topic [5].

The quadratic convex (QC) relaxation is a promising approach that encloses the trigonometric and product terms in the polar representation of power flow equations within convex envelopes [11]. These envelopes are formed with linear and second-order cone programming (SOCP) constraints, resulting in a convex formulation. The QC relaxation’s tightness strongly depends on the quality of these convex envelopes. This paper focuses on improving these envelopes.

Previous work has proposed a variety of approaches for tightening the QC relaxation. These include valid inequalities, such as “Lifted Nonlinear Cuts” [12], [13] and constraints that exploit bounds on the differences in the voltage magnitudes [14]. Additionally, since the accuracies of the trigonometric and product envelopes in the QC relaxation rely on the voltage magnitude and angle difference bounds, bound tightening approaches can significantly strengthen the QC relaxation [12], [15]–[19]. When bound tightening approaches provide sign-definite angle difference bounds (i.e., the upper and lower bounds on the angle differences have the same sign), tighter trigonometric envelopes can be applied [12].

This paper proposes two improvements to further tighten QC relaxations of OPF problems. The first improvement leverages a polar representation of the branch admittances in addition to the rectangular representation used in previous QC formulations. Within certain ranges, portions of the trigonometric envelopes resulting from the polar admittance representation are at least as tight (and generally tighter) than the corresponding portions of the envelopes from the rectangular admittance representation. In other ranges, the trigonometric envelopes from the polar admittance representation neither contain nor are contained within the
envelopes from the rectangular admittance representation. Thus, combining these envelopes tightens the QC relaxation, with empirical results suggesting limited impacts on solution times. The polar admittance representation also enables our second improvement. We exploit a degree of freedom in the OPF formulation related to the per unit base power normalization. Selecting a complex base power $S_{\text{base}} = |S_{\text{base}}|e^{j\psi}$ results in a coordinate transformation that rotates the power flow equations relative to the typical choice of a real-valued base power. We leverage the associated rotational degree of freedom $\psi$ to obtain tighter envelopes for the trigonometric functions. While previously proposed power flow algorithms [20] and state estimation algorithms [21] use similar formulations, this paper is, to the best of our knowledge, the first to exploit this rotational degree of freedom to improve convex relaxations.

This paper is organized as follows. Sections II and III review the OPF formulation and the previously proposed QC relaxation, respectively. Section IV describes the coordinate changes underlying our improved QC relaxation. Section V then presents these improvements. Section VI empirically evaluates our approach. Section VII concludes the paper. An extended version of this paper in [22] further describes and analyzes the envelopes used in the relaxation and also considers parallel lines and more general line models.

II. OVERVIEW OF THE OPTIMAL POWER FLOW PROBLEM

This section formulates the OPF problem using a polar voltage phasor representation. The sets of buses, generators, and lines are $\mathcal{N}, \mathcal{G},$ and $\mathcal{L}$, respectively. The set $\mathcal{R}$ contains the index of the bus that sets the angle reference. Let $S_i^d = P_i^d + jQ_i^d$ and $S_i^q = P_i^q + jQ_i^q$ represent the complex load demand and generation, respectively, at bus $i \in \mathcal{N}$, where $j = \sqrt{-1}$. Let $V_i$ and $\theta_i$ represent the voltage magnitude and angle at bus $i \in \mathcal{N}$. Let $g_{sh,i} + jh_{sh,i}$ denote the shunt admittance at bus $i \in \mathcal{N}$. For each generator, define a quadratic cost function with coefficients $c_{2,i}, c_{1,i}, c_{0,i}$. For simplicity, we consider a single generator at each bus by setting the generation limits at a coordinate transformation that rotates the power flow equations relative to the typical choice of a real-valued base power. We leverage the associated rotational degree of freedom $\psi$ to obtain tighter envelopes for the trigonometric functions. While previously proposed power flow algorithms [20] and state estimation algorithms [21] use similar formulations, this paper is, to the best of our knowledge, the first to exploit this rotational degree of freedom to improve convex relaxations.

The polar admittance representation also enables our second improvement. We exploit a degree of freedom in the OPF formulation related to the per unit base power normalization. Selecting a complex base power $S_{\text{base}} = |S_{\text{base}}|e^{j\psi}$ results in a coordinate transformation that rotates the power flow equations relative to the typical choice of a real-valued base power. We leverage the associated rotational degree of freedom $\psi$ to obtain tighter envelopes for the trigonometric functions. While previously proposed power flow algorithms [20] and state estimation algorithms [21] use similar formulations, this paper is, to the best of our knowledge, the first to exploit this rotational degree of freedom to improve convex relaxations.

The objective (1a) minimizes the generation cost. Constraints (1b) and (1c) enforce power balance at each bus. Constraint (1d) sets the reference bus angle. The constraints in (1e) bound the active and reactive power generation at each bus. Constraints (1f)–(1g), respectively, bound the voltage magnitudes and voltage angle differences. Constraints (1h)–(1k) relate the active and reactive power flows with the voltage phasors at the terminal buses. The constraints in (1l) limit the apparent power flows into both terminals of each line.

III. THE QC RELAXATION OF THE OPF PROBLEM

The QC relaxation convexifies the OPF problem (1) by enclosing the nonconvex terms in convex envelopes [11]. The relevant nonconvex terms are the square $V_i^2$, $\forall i \in \mathcal{N}$, and the products $V_i V_m \cos(\theta_{im})$ and $V_i V_m \sin(\theta_{im})$, $\forall (i,m) \in \mathcal{L}$. The envelope for the generic squared function $x^2$ is $(x^2)_T$:

\[
(x^2)_T = \begin{cases} x \geq x^2, \\ \bar{x} \leq (\bar{x} + x) x - \bar{x} \end{cases},
\]

where $\bar{x}$ is a lifted variable representing the squared term. Envelopes for the generic trigonometric functions $\sin(x)$ and $\cos(x)$ are $(\sin(x))^S$ and $(\cos(x))^C$:

\[
(\sin(x))^S = \begin{cases} \tilde{S} \leq \cos \left( \frac{x^*}{2} \right) (x - \bar{x}) + \sin \left( \frac{x^*}{2} \right) \text{ if } x \geq 0 \leq \bar{x}, \\ \tilde{S} \geq \cos \left( \frac{x^*}{2} \right) (x + \bar{x}) - \sin \left( \frac{x^*}{2} \right) \text{ if } x \leq 0 \leq \bar{x}, \\ \tilde{S} \geq \sin \left( \frac{x^*}{2} \right) (x - \bar{x}) + \sin (x) \text{ if } x \geq 0, \\ \tilde{S} \leq \sin \left( \frac{x^*}{2} \right) (x - \bar{x}) + \sin (x) \text{ if } x \leq 0 \end{cases},
\]

\[
(\cos(x))^C = \begin{cases} \tilde{C} \leq 1 - \cos \left( \frac{x^*}{2} \right) x^2, \\ \tilde{C} \geq \cos \left( \frac{x^*}{2} \right) (x - \bar{x}) + \cos (x) \end{cases},
\]
where $x^m = \max(|x|, |\gamma|)$. The envelopes $\langle \sin(x) \rangle^S$ and $\langle \cos(x) \rangle^C$ in (3) and (4) are valid for $-\frac{\pi}{2} \leq x \leq \frac{\pi}{2}$. Similar envelopes for the sine and cosine functions are defined analogously for other angle difference ranges. (See [22, Appendix A].)

The lifted variables $S$ and $C$ are associated with the envelopes for the functions $\sin(\theta_{lm})$ and $\cos(\theta_{lm})$. The QC relaxation of the OPF problem in (1) is:

$$
\begin{align}
\min & \sum_{i \in \mathcal{N}} c_{2,i} (P^g_i)^2 + c_{1,i} P^g_i + c_{0,i} \\
\text{subject to} & \quad (\forall i \in \mathcal{N}, \forall (l, m) \in \mathcal{L}) \\
& \quad P^g_i - P^d_i = g_{s,h,i} w_{ii} + \sum_{(l,m) \in \mathcal{L}, \text{s.t. } l = i} P_{lm} + \sum_{(l,m) \in \mathcal{L}, \text{s.t. } m = i} P_{ml}, \\
& \quad Q^g_i - Q^d_i = -b_{s,h,i} w_{ii} + \sum_{(l,m) \in \mathcal{L}, \text{s.t. } l = i} Q_{lm} + \sum_{(l,m) \in \mathcal{L}, \text{s.t. } m = i} Q_{ml}, \\
& \quad \theta_r = 0, \quad r \in \mathcal{R}, \\
& \quad P^g_i \leq P^d_i \leq P^g, \quad Q^g_i \leq Q^d_i \leq Q^g, \\
& \quad V_i \leq V_i \leq \overline{V}_i, \\
& \quad \underline{\theta}_{lm} \leq \theta_{lm} \leq \overline{\theta}_{lm}, \\
& \quad (V_i)^2 \leq w_{ii} \leq (\overline{V}_i)^2, \quad w_{ii} \in \langle V_i^2 \rangle^T, \\
& \quad P_{lm} = g_{lm} w_{ii} - g_{im} c_{lm} - b_{lm} s_{lm}, \\
& \quad Q_{lm} = -(b_{lm} + b_{c,lm}/2) w_{ii} + b_{lm} c_{lm} - g_{lm} s_{lm}, \\
& \quad P_{ml} = g_{lm} w_{mm} - g_{ml} c_{lm} + b_{lm} s_{lm}, \\
& \quad Q_{ml} = -(b_{lm} + b_{c,lm}/2) w_{mm} + b_{lm} c_{lm} + g_{lm} s_{lm}, \\
& \quad (P_{lm})^2 + (Q_{lm})^2 \leq (\overline{S}_{lm})^2, \quad (P_{ml})^2 + (Q_{ml})^2 \leq (\overline{S}_{lm})^2, \\
& \quad c_{lm} = \sum_{k=1,\ldots,8} \lambda_k p^{(k)}_l p^{(k)}_m, \quad \overline{C}_{lm} \in \langle \cos(\theta_{lm}) \rangle^C, \\
& \quad V_l = \sum_{k=1,\ldots,8} \lambda_k p^{(k)}_l, \quad V_m = \sum_{k=1,\ldots,8} \lambda_k p^{(k)}_m, \quad \overline{C}_{lm} = \sum_{k=1,\ldots,8} \lambda_k p^{(k)}_l p^{(k)}_m, \\
& \quad \sum_{k=1,\ldots,8} \lambda_k = 1, \quad \lambda_k \geq 0, \quad k = 1,\ldots,8, \\
& \quad s_{lm} = \sum_{k=1,\ldots,8} \gamma_k \xi^{(k)}_l \xi^{(k)}_m, \quad \overline{S}_{lm} \in \langle \sin(\theta_{lm}) \rangle^S, \\
& \quad V_l = \sum_{k=1,\ldots,8} \gamma_k \xi^{(k)}_l, \quad V_m = \sum_{k=1,\ldots,8} \gamma_k \xi^{(k)}_m, \quad \overline{S}_{lm} = \sum_{k=1,\ldots,8} \gamma_k \xi^{(k)}_l \xi^{(k)}_m, \\
& \quad \sum_{k=1,\ldots,8} \gamma_k = 1, \quad \gamma_k \geq 0, \quad k = 1,\ldots,8.
\end{align}
$$

where $\ell_{lm}$ represents the squared magnitude of the current flow into terminal $l$ of line $(l, m) \in \mathcal{L}$ and $(\cdot)^T$ is the transpose operator. The relationship between $\ell_{lm}$ and the power flows $P_{lm}$ and $Q_{lm}$ in (5p) tightens the QC relaxation [11, 23]. Appendix A in [22] gives an expression for $\ell_{lm}$ that considers lines with off-nominal tap ratios and non-zero phase shifts. Also, as shown in (5h), $w_{ii}$ is associated with the squared voltage magnitude at bus $i$.

The lifted variables $c_{lm}$ and $s_{lm}$ represent relaxations of the trilinear terms $V_l V_m \cos(\theta_{lm})$ and $V_l V_m \sin(\theta_{lm})$, respectively, with (5n) and (5o) formulating an “extreme point” representation of the convex hulls for the trilinear terms $V_l V_m \overline{C}_{lm}$ and $V_l V_m \overline{S}_{lm}$ [6, 24]. The auxiliary variables $\lambda_k, \gamma_k \in [0,1], k = 1,\ldots,8,$ are used in the formulations of these convex hulls. The extreme points of $V_l V_m \overline{C}_{lm}$ are $\rho(k) \in [V_l, V_m] \times [\overline{C}_{lm}, \overline{S}_{lm}], k = 1,\ldots,8$ and the extreme points of $V_l V_m \overline{S}_{lm}$ are $\zeta(k) \in [V_l, V_m] \times [\overline{S}_{lm}, \overline{S}_{lm}], k = 1,\ldots,8$. Since sine and cosine are odd and even functions, respectively, $c_{lm} = c_{ml}$ and $s_{lm} = -s_{ml}$.

A “linking constraint” from [19] is also enforced in (5r). This linking constraint is associated with the bilinear terms $V_l V_m$ that are shared in $V_l V_m \cos(\theta_{lm})$ and $V_l V_m \sin(\theta_{lm})$.

IV. COORDINATE TRANSFORMATIONS

The improvements to the QC relaxation’s envelopes that are our main contributions are based on certain coordinate transformations. This section describes these transformations. We first form the power flow equations using polar representations of the lines’ mutual admittances. We then introduce a complex base power in the per unit normalization that provides a rotational degree of freedom in the power flow equations.

While this section uses a PI circuit line model for simplicity, extensions to more general line models are straightforward. These extensions are presented in [22, Appendix A].

A. Power Flow Equations With Admittance in Polar Form

Equations (1h)–(1k) model the power flows through a line $(l, m) \in \mathcal{L}$ via a rectangular representation of the line’s mutual admittance, $g_{lm} + j b_{lm}$. In (5i)–(5l), the QC relaxation from [11] uses this rectangular admittance representation.

The line flows can be equivalently modeled using a polar representation of the mutual admittance, $Y_{lm} e^{j \delta_{lm}}$, where
$Y_{lm} = \sqrt{g_{lm}^2 + b_{lm}^2}$ and $\delta_{lm} = \arctan(b_{lm}/g_{lm})$ are the magnitude and angle of the mutual admittance for line $(l, m) \in \mathcal{L}$, respectively. Using polar admittance coordinates, the complex power flows $S_{lm}$ and $S_{ml}$ into each line terminal are:

$$S_{lm} = V_l e^{j\theta_l} \left( Y_{lm} e^{j\delta_{lm}} + j \frac{b_{lm}}{2} ight) V_m e^{j\theta_m},$$

(6a)

$$S_{ml} = V_m e^{j\theta_m} \left( -Y_{lm} e^{j\delta_{lm}} V_l e^{j\theta_l} + \left( Y_{lm} e^{j\delta_{lm}} + j \frac{b_{lm}}{2} \right) V_m e^{j\theta_m} \right),$$

(6b)

where $(\cdot)^*$ is the complex conjugate. Taking the real and imaginary parts of (6) yields the active and reactive line flows:

$$P_{lm} = \text{Re}(S_{lm}) = Y_{lm} \cos(\delta_{lm}) V_l^2 - Y_{lm} V_l V_m \cos(\theta_{lm} - \delta_{lm}),$$

(7a)

$$Q_{lm} = \text{Im}(S_{lm}) = -Y_{lm} \sin(\delta_{lm}) + \frac{b_{lm}}{2} V_l^2 - Y_{lm} V_l V_m \sin(\theta_{lm} - \delta_{lm}),$$

(7b)

$$P_{ml} = \text{Re}(S_{ml}) = Y_{lm} \cos(\delta_{lm}) V_m^2 - Y_{lm} V_l V_m \cos(\theta_{lm} + \delta_{lm}),$$

(7c)

$$Q_{ml} = \text{Im}(S_{ml}) = -Y_{lm} \sin(\delta_{lm}) + \frac{b_{lm}}{2} V_m^2 + Y_{lm} V_l V_m \sin(\theta_{lm} + \delta_{lm}).$$

(7d)

With the rectangular admittance representation, the active and reactive power flow equations (1h)–(1i) each have two trigonometric terms (i.e., $\cos(\theta_{lm})$ and $\sin(\theta_{lm})$). Conversely, there is only one trigonometric term in each of the power flow equations that use the polar admittance representation (7) (e.g., $\cos(\theta_{lm} - \delta_{lm})$ for $P_{lm}$ and $\sin(\theta_{lm} - \delta_{lm})$ for $Q_{lm}$). While these formulations are equivalent, the differing representations of the trigonometric terms suggest the possibility of using different trigonometric envelopes. The QC formulation we will propose in Section V-C exploits these differences.

### B. Rotated Power Flow Formulation

The base power used in the per unit normalization is traditionally chosen to be a real-valued quantity. More generally, complex-valued choices for the base power are also acceptable and can provide benefits for some algorithms. For instance, certain power flow [20] and state estimation algorithms [21], [25] leverage formulations with a complex-valued base power.

To improve the QC relaxation’s trigonometric envelopes, this section reformulates the OPF problem with a complex base power. Let $S_{\text{base}}^{\text{orig}}$ and $S_{\text{base}}^{\text{new}} e^{j\psi}$ denote the original and the new base power, respectively, where $S_{\text{base}}^{\text{orig}}$, $S_{\text{base}}^{\text{new}}$, and $\psi$ are real-valued. Thus, the original base $S_{\text{base}}^{\text{orig}}$ is real-valued, while the new base $S_{\text{base}}^{\text{new}} e^{j\psi}$ is complex-valued with magnitude $S_{\text{base}}^{\text{new}}$ and angle $\psi$. Quantities associated with the new base power will be accented with a tilde, $(\tilde{\cdot})$. Complex power flows in the original base and the new base are related as:

$$\tilde{S}_{lm} = S_{lm} \cdot \frac{S_{\text{base}}^{\text{orig}}}{S_{\text{base}}^{\text{new}} e^{j\psi}} = S_{lm} \cdot \frac{P_{i}^{\text{orig}} + jQ_{i}^{\text{orig}}}{P_{i}^{\text{new}} e^{j\psi}}.$$  

(8a)

$$\tilde{S}_{ml} = S_{ml} \cdot \frac{S_{\text{base}}^{\text{orig}}}{S_{\text{base}}^{\text{new}} e^{j\psi}}.$$  

(8b)

Since changing the magnitude of the base power does not affect the arguments of the trigonometric functions in the power flow equations, we choose $S_{\text{base}}^{\text{new}} = S_{\text{base}}^{\text{old}}$. With this choice,

$$\tilde{S}_{lm} = S_{lm} / e^{j\psi}, \quad \tilde{S}_{ml} = S_{ml} / e^{j\psi}.$$  

The angle of the base power, $\psi$, affects the arguments of the trigonometric functions, as shown in the following derivation:

$$\tilde{S}_{lm} = S_{lm} / e^{j\psi} = \left( Y_{lm} e^{-j(\delta_{lm} + \psi)} + (b_{c,l,m}/2) e^{-j(\delta_{lm} + \psi)} \right) V_l^2 - Y_{lm} V_l V_m e^{j(\delta_{lm} + \theta_{lm} - \psi)}.$$

(8a)

$$\tilde{S}_{ml} = S_{ml} / e^{j\psi} = \left( Y_{lm} e^{-j(\delta_{lm} + \psi)} + (b_{c,l,m}/2) e^{-j(\delta_{lm} + \psi)} \right) V_m^2 - Y_{lm} V_l V_m e^{-j(\delta_{lm} + \theta_{lm} + \psi)}.$$  

(8b)

Taking the real and imaginary parts of (8) yields:

$$\tilde{P}_{lm} = \text{Re}(\tilde{S}_{lm}) = Y_{lm} \cos(\delta_{lm} + \psi) - (b_{c,l,m}/2) \sin(\psi) \right) V_l^2 - Y_{lm} V_l V_m \cos(\theta_{lm} - \delta_{lm} - \psi),$$

(9a)

$$\tilde{Q}_{lm} = \text{Im}(\tilde{S}_{lm}) = -Y_{lm} \sin(\delta_{lm} + \psi) + (b_{c,l,m}/2) \cos(\psi) V_l^2 - Y_{lm} V_l V_m \sin(\theta_{lm} - \delta_{lm} - \psi),$$

(9b)

$$\tilde{P}_{ml} = \text{Re}(\tilde{S}_{ml}) = Y_{lm} \cos(\delta_{lm} + \psi) - (b_{c,l,m}/2) \sin(\psi) V_m^2 - Y_{lm} V_l V_m \cos(\theta_{lm} + \delta_{lm} + \psi),$$

(9c)

$$\tilde{Q}_{ml} = \text{Im}(\tilde{S}_{ml}) = -Y_{lm} \sin(\delta_{lm} + \psi) + (b_{c,l,m}/2) \cos(\psi) V_m^2 + Y_{lm} V_l V_m \sin(\theta_{lm} + \delta_{lm} + \psi).$$  

(9d)

The arguments of the trigonometric functions $\cos(\theta_{lm} - \delta_{lm} - \psi)$, $\sin(\theta_{lm} - \delta_{lm} - \psi)$, $\cos(\delta_{lm} + \delta_{lm} + \psi)$, and $\sin(\theta_{lm} + \delta_{lm} + \psi)$ in (9) are linear in $\psi$. For a given $\psi$, all other trigonometric terms in (9) are constants that do not require special handling.

### C. Rotated OPF Problem

We next represent the complex power generation and load demands using the new base power:

$$\tilde{S}_{i}^{\theta} = S_{i}^{\theta} \cdot \frac{S_{\text{base}}^{\text{orig}}}{S_{\text{base}}^{\text{new}} e^{j\psi}} = S_{i}^{\theta} \cdot \frac{P_{i}^{\text{orig}} + jQ_{i}^{\text{orig}}}{P_{i}^{\text{new}} e^{j\psi}}.$$  

Define $\tilde{S}_{i}^{\theta} = \tilde{P}_{i}^{\theta} + j\tilde{Q}_{i}^{\theta}$, $\forall i \in \mathcal{N}$. Taking the real and imaginary parts of $\tilde{S}_{i}^{\theta}$ yields the following relationship between the power generation in the new and original bases:

$$\begin{bmatrix} \tilde{P}_{i}^{\theta} \\ \tilde{Q}_{i}^{\theta} \end{bmatrix} = \begin{bmatrix} \cos(\psi) & \sin(\psi) \\ -\sin(\psi) & \cos(\psi) \end{bmatrix} \begin{bmatrix} P_{i}^{\theta} \\ Q_{i}^{\theta} \end{bmatrix}.$$  

(10)

The inverse relationship is well defined for any choice of $\psi$ since the matrix in (10) is invertible.
The analogous relationship for the power demands is:

\[
\begin{bmatrix}
\hat{P}_i^d
\end{bmatrix} = \begin{bmatrix}
\cos(\psi) & \sin(\psi) \\
-\sin(\psi) & \cos(\psi)
\end{bmatrix}
\begin{bmatrix}
\hat{Q}_i^d
\end{bmatrix}.
\]  

(11)

Applying (9)–(11) to (1) yields a “rotated” OPF problem:

\[
\begin{aligned}
\min \quad & \sum_{l \in G} c_{2,l} \left( \hat{P}_l^P \cos(\psi) - \hat{Q}_l^P \sin(\psi) \right)^2 \\
+ & c_{1,l} \left( \hat{P}_l^T \cos(\psi) - \hat{Q}_l^T \sin(\psi) \right) + c_{0,i}\end{aligned}
\]

subject to \( (\forall i \in \mathcal{N}, \forall (l,m) \in \mathcal{L}) \)

\[
\begin{aligned}
P_i^g - \hat{P}_i^g &= (g_{sh,i} \cos(\psi) - b_{sh,i} \sin(\psi)) V_i^2 \\
+ & \sum_{(l,m) \in \mathcal{L}, l=i} P_{ml} + \sum_{(l,m) \in \mathcal{L}, m=i} P_{ml}, \\
\hat{Q}_i^q - \hat{Q}_i^q &= -(g_{sh,i} \sin(\psi) + b_{sh,i} \cos(\psi)) V_i^2 \\
+ & \sum_{(l,m) \in \mathcal{L}, l=i} Q_{ml} + \sum_{(l,m) \in \mathcal{L}, m=i} Q_{ml}, \\
\theta_r = 0, \quad r \in \mathcal{R},
\end{aligned}
\]

(12a)

(12b)

(12c)

(12d)

(12e)

(12f)

(12g)

(12h)

The rotated OPF problem (12) is equivalent to (1) in that any solution \{\(\bar{V}^*, \theta^*, \bar{P}^*, \bar{Q}^*\)\} to (12) can be mapped to a solution \{\(V^*, \theta^*, \bar{P}^*, \bar{Q}^*\)\} to (1) using (10). Solutions to both formulations have the same voltage magnitudes and angles, \(V^*\) and \(\theta^*\).

Thus, (12) can be interpreted as revealing a degree of freedom associated with choosing the base power angle \(\psi\) in order to tighten the relaxation for typical OPF problems.

V. ROTATED QC RELAXATION

This section leverages the coordinate transformations presented in Section IV to tighten the QC relaxation. We first propose and analyze new envelopes for the trigonometric functions and trilinear terms. We then describe an empirical analysis that informs the choice of the base power angle \(\psi\) in order to tighten the relaxation for typical OPF problems.

A. Convex Envelopes for the Trigonometric Terms

A key determinant of the QC relaxation’s tightness is the quality of the convex envelopes for the trigonometric terms in the power flow equations. The rotated OPF formulation (12) has four relevant trigonometric terms for each line: \(\cos(\theta_{lm} - \delta_{lm} - \psi), \sin(\theta_{lm} - \delta_{lm} - \psi), \cos(\theta_{lm} + \delta_{lm} + \psi), \) and \(\sin(\theta_{lm} + \delta_{lm} + \psi), \forall (l,m) \in \mathcal{L}\). This contrasts with the two unique trigonometric terms \(\cos(\theta_{lm})\) and \(\sin(\theta_{lm})\) per pair of connected buses in the OPF formulation (1).

This would seem to suggest that at least twice as many lifted variables would be required in order to relax the rotated OPF formulation (12) compared to the original OPF formulation (1), i.e., \(C_{lm}^{\hat{C}}\) or \(C_{lm}^{\hat{S}}\) and \(S_{lm}^{\hat{C}}\) or \(S_{lm}^{\hat{S}}\). For relaxing the sending end quantities \(\cos(\theta_{lm} - \delta_{lm} - \psi), \sin(\theta_{lm} - \delta_{lm} - \psi)\) and the receiving end quantities \(\cos(\theta_{lm} + \delta_{lm} + \psi), \sin(\theta_{lm} + \delta_{lm} + \psi)\) in (12) versus \(C_{lm}\) and \(S_{lm}\) for relaxing \(\cos(\theta_{lm})\) and \(\sin(\theta_{lm})\) in (1). However, this is not the case since the arguments of the trigonometric terms in the rotated OPF formulation are not independent. For notational convenience, define \(\tilde{\delta}_{lm} = \delta_{lm} + \psi\). The angle sum and difference identities imply the following relationships:

\[
\begin{bmatrix}
\sin(\tilde{\delta}_{lm} + \tilde{\theta}_{lm}) \\
\cos(\tilde{\delta}_{lm} + \tilde{\theta}_{lm})
\end{bmatrix} = \begin{bmatrix}
\sin(\delta_{lm}) & \cos(\delta_{lm}) \\
\cos(\delta_{lm}) & -\sin(\delta_{lm})
\end{bmatrix}
\begin{bmatrix}
\cos(\theta_{lm}) \\
\sin(\theta_{lm})
\end{bmatrix}.
\]

(13)

Rearranging these relationships yields:

\[
\begin{bmatrix}
\sin(\theta_{lm} + \delta_{lm}) \\
\cos(\theta_{lm} + \delta_{lm})
\end{bmatrix} = \begin{bmatrix}
\alpha_{lm} & \beta_{lm} \\
-\beta_{lm} & \alpha_{lm}
\end{bmatrix}\begin{bmatrix}
\sin(\theta_{lm} - \delta_{lm}) \\
\cos(\theta_{lm} - \delta_{lm})
\end{bmatrix}.
\]

(14)

where, for notational convenience, \(\alpha_{lm} = (\cos(\delta_{lm})\) \(-\sin(\delta_{lm})\) \and \(\beta_{lm} = 2 \cos(\delta_{lm})\sin(\delta_{lm})\). The implication of (14) is that only two (rather than four) lifted variables are defined per line (chosen to be the sending end quantities \(C_{lm}^{\hat{C}}\) and \(S_{lm}^{\hat{S}}\) for relaxing the trigonometric terms \(\cos(\theta_{lm} - \delta_{lm})\) and \(\sin(\theta_{lm} - \delta_{lm})\)). The remaining trigonometric functions, \(\sin(\theta_{lm} + \delta_{lm})\) and \(\cos(\theta_{lm} + \delta_{lm})\), are representable in terms of \(\sin(\theta_{lm} - \delta_{lm})\) and \(\cos(\theta_{lm} - \delta_{lm})\) via the linear transformation (14). Since the matrix in (14) is invertible for all \(\tilde{\delta}_{lm}\), the transformation (14) is always well-defined.

While not explicitly including the lifted variables \(\hat{C}_{lm}^{\hat{S}}\) and \(\hat{S}_{lm}^{\hat{S}}\) for the receiving end quantities, we tighten the relaxation of (12) by enforcing the trigonometric envelopes associated with both the sending and receiving end quantities using (14):

\[
\begin{aligned}
\hat{C}_{lm}^{\hat{S}} &\in \langle \cos(\theta_{lm} - \delta_{lm} - \psi) \rangle^C, \\
\hat{S}_{lm}^{\hat{S}} &\in \langle \sin(\theta_{lm} - \delta_{lm} - \psi) \rangle^S, \\
\alpha_{lm} \hat{C}_{lm}^{\hat{S}} + \beta_{lm} \hat{C}_{lm}^{\hat{S}} &\in \langle \sin(\theta_{lm} + \delta_{lm} + \psi) \rangle^S, \\
-\beta_{lm} \hat{C}_{lm}^{\hat{S}} + \alpha_{lm} \hat{C}_{lm}^{\hat{S}} &\in \langle \cos(\theta_{lm} + \delta_{lm} + \psi) \rangle^C.
\end{aligned}
\]

(15a)

(15b)

(16a)

(16b)

Related special consideration is needed for parallel lines. While the rest of this section considers systems without parallel lines for simplicity, [22, Appendix B] discusses this issue in detail. Using the linear relationships in (14), all relevant trigonometric terms in (12) can be represented as linear combinations of \(\sin(\theta_{lm} - \delta_{lm} - \psi)\) and \(\cos(\theta_{lm} - \delta_{lm} - \psi)\) for each unique pair of connected buses \((l, m) \in \mathcal{L}\). The QC relaxations of (1) and (12) hence have the same number of lifted variables (two per pair of connected buses).
There are two characteristics that distinguish the trigonometric expressions in (1) and (12): First, the power flow equations (1h)–(1k) contain weighted sums of two trigonometric functions of $\theta_{lm}$, while (9a)–(9d) each contain a single trigonometric function of $\theta_{lm}$. (The trigonometric expressions $\cos(\delta_{lm} + \psi)$, $\sin(\delta_{lm} + \psi)$, $\cos(\psi)$, and $\sin(\psi)$ in (9a)–(9d) are constants that do not require special consideration.) Second, the base power angle $\psi$ used to formulate (12) provides a degree of freedom that shifts the arguments of the trigonometric functions in (9a)–(9d). We next discuss how both of these characteristics can be exploited to tighten the QC relaxation.

Regarding the first distinguishing characteristic, factorizing out $-V_l V_m$ to focus on the trigonometric functions shows that the relaxation of (1h) depends on the quality of a weighted sum of trigonometric envelopes: $g_{lm} \langle \cos(\theta_{lm}) \rangle_C^C + b_{lm} \langle \sin(\theta_{lm}) \rangle_S^C$.

The relaxation of (9a) depends on the quality of the envelope $Y_{lm} \langle \cos(\theta_{lm} - \delta_{lm} - \psi) \rangle_C^C$. (The relaxations of (1h)–(1k) and (9a)–(9d) are analogous.) To focus on the first characteristic, consider the latter envelope with $\psi = 0$.

Fig. 1 illustrates examples of these envelopes for a line with the same mutual admittance ($g_{lm} + j b_{lm} = 0.6 - j0.8$) for different intervals of angle differences ($\theta_{lm} \leq \theta_{lm} \leq \bar{\theta}_{lm}$). While transmission lines with such large resistances are atypical, we choose this admittance to better visualize our approach in Fig. 1. Our approach is valid for all values of line admittances.

To compare these envelopes, we consider their boundaries. As shown in [22, Appendix C], either the upper or lower boundary of the envelope $Y_{lm} \langle \cos(\theta_{lm}) \rangle_C^C$ is at least as tight (and sometimes tighter) compared to the corresponding boundary of the envelope $g_{lm} \langle \cos(\theta_{lm}) \rangle_C^C + b_{lm} \langle \sin(\theta_{lm}) \rangle_S^C$ for certain values of $\delta_{lm}$, $\theta_{lm}$, and $\gamma_{lm}$. In this case, there is no general dominance relationship for the other boundary. For other values of $\delta_{lm}$, $\gamma_{lm}$, and $\theta_{lm}$, none of the boundaries of the envelope $Y_{lm} \langle \cos(\theta_{lm} - \delta_{lm}) \rangle_C$ dominate or are dominated by a boundary of the envelope $g_{lm} \langle \cos(\theta_{lm}) \rangle_C^C + b_{lm} \langle \sin(\theta_{lm}) \rangle_S^C$.

Thus, a QC relaxation that enforces the intersection of these envelopes is generally tighter than relaxations constructed using either of these envelopes individually. Section V-D discusses this further.

The second characteristic distinguishing between the envelopes for (1) and (12) is the ability to choose $\psi$ in the latter envelopes. As shown in Fig. 2, changing $\psi$ rotates the arguments of these envelopes. We also visualize the impacts that different values of $\psi$ have on the sine and cosine envelopes in an animation available at https://arxiv.org/src/1912.05061v3/anc/rotated-envelope_animation.gif.

Analytically comparing the impacts of different values for $\psi$ is not straightforward. Accordingly, this section will later describe an empirical study that suggests a good choice for $\psi$ for typical OPF problems.

**B. Envelopes for Trilinear Terms**

In addition to the trigonometric functions considered thus far, the products between the voltage magnitudes and the trigonometric functions in (9) are another source of non-convexity.

![Fig. 1](https://arxiv.org/src/1912.05061v3/anc/rotated_envelope_animation.gif)
in the rotated OPF problem (12). We next exploit the relationship between the sending and receiving end trigonometric functions (14) in order to relax these products using a limited number of additional lifted variables.

Similar to (5n)–(5o), we relax the trilinear products by constructing linear envelopes using the upper and lower bounds on \( V_l, V_m, \cos(\theta_l - \delta_l - \psi), \sin(\theta_l - \delta_l - \psi), \cos(\theta_l + \delta_l + \psi), \) and \( \sin(\theta_l + \delta_l + \psi) \). We use the linear relationship (14) to represent the upper and lower bounds on the receiving end quantities \( \cos(\theta_l + \delta_l + \psi) \) (denoted \( \tilde{C}_{lm}^{(r)}, \tilde{C}_{lm}^{(s)} \)) and \( \sin(\theta_l + \delta_l + \psi) \) (denoted \( \tilde{S}_{lm}^{(r)}, \tilde{S}_{lm}^{(s)} \)) in terms of the bounds on the sending end quantities \( \cos(\theta_l - \delta_l - \psi) \) (denoted \( \tilde{C}_{lm}^{(s)}, \tilde{C}_{lm}^{(r)} \)) and \( \sin(\theta_l - \delta_l - \psi) \) (denoted \( \tilde{S}_{lm}^{(s)}, \tilde{S}_{lm}^{(r)} \)). We then enforce constraints on the sending end quantities derived from the intersection of the transformed bounds associated with the receiving end quantities along with the bounds on the sending end quantities. Intersecting these bounds forms a polytope in terms of the sending end quantities \( \tilde{C}_{lm}^{(s)} \) (representing \( \cos(\theta_l - \delta_l - \psi) \)) and \( \tilde{S}_{lm}^{(s)} \) (representing \( \sin(\theta_l - \delta_l - \psi) \)), expressible as a convex combination of its extreme points.

Fig. 3 shows the bounds on both the sending and receiving end quantities in terms of the sending end quantities. The yellow region is the polytope formed by the bounds on \( \cos(\theta_l - \delta_l - \psi) \) and \( \sin(\theta_l - \delta_l - \psi) \). The red region is the polytope formed by using (14) to represent the bounds on the receiving end quantities \( \cos(\theta_l + \delta_l + \psi) \) and \( \sin(\theta_l + \delta_l + \psi) \) in terms of the sending end quantities \( \cos(\theta_l - \delta_l - \psi) \) and \( \sin(\theta_l - \delta_l - \psi) \). The black dots are the vertices of the polytope shown by the dashed black lines formed from the intersection of the yellow and red polytopes. Appendix D in [22] shows how to compute these vertices.

Enforcing the constraints associated with both the yellow and red polytopes adds an unnecessary computational burden. We instead restrict the sending end quantities \( \cos(\theta_l - \delta_l - \psi) \) and \( \sin(\theta_l - \delta_l - \psi) \) to lie within the polytope shown by the black dashed line in Fig. 3. This implicitly ensures satisfaction of the bounds on the receiving end quantities.

To relax the product terms \( V_l V_m \cos(\theta_l - \delta_l - \psi) \) and \( V_l V_m \sin(\theta_l - \delta_l - \psi) \), we first represent the quantities \( \cos(\theta_l - \delta_l - \psi) \) and \( \sin(\theta_l - \delta_l - \psi) \) using lifted variables \( \tilde{C}_{lm}^{(s)} \) and \( \tilde{S}_{lm}^{(s)} \), respectively. We then extend the polytope shown by the black dashed lines in Fig. 3 using the upper and lower bounds on \( V_l \) and \( V_m \). The resulting four-dimensional polytope is the convex hull of the quadrilinear polynomial \( V_l V_m \tilde{C}_{lm}^{(s)} \tilde{S}_{lm}^{(s)} \), which we represent using an extreme point formulation similar to (5n)–(5o). Let \( \bar{T}_{lm} = \{ (\tilde{C}_{lm}^{(s)1}, \tilde{S}_{lm}^{(s)1}) \), \( (\tilde{C}_{lm}^{(s)2}, \tilde{S}_{lm}^{(s)2}) \), \ldots, \( (\tilde{C}_{lm}^{(s)N}, \tilde{S}_{lm}^{(s)N}) \} \) denote the coordinates of the intersection points (black dots) in Fig. 3, where \( \bar{N} \) is the number of intersection points which ranges from 4 to 8 depending on the value of \( \psi \). The extreme points of \( V_l V_m \tilde{C}_{lm}^{(s)} \tilde{S}_{lm}^{(s)} \) are then denoted as \( \eta^{(k)} \in [V_l, V_m] \times \)}
\[ [V_{im}, \overline{V}_{im}] \times T_{im}, \ k = 1, \ldots, 4\tilde{N}. \] The auxiliary variables \( \lambda_k \in [0,1], \ k = 1, \ldots, 4\tilde{N}, \) are used to form the convex hull of the quadrilinear term \( V_{im} \tilde{C}_{lm}^{(s)} \tilde{S}_{lm}^{(s)}. \)

The envelopes for the trilinear terms are:
\[
\tilde{c}_{lm} = \sum_{k=1,\ldots,4\tilde{N}} \lambda_k \tilde{C}_{lm}^{(s)}(k), \quad \tilde{s}_{lm} = \sum_{k=1,\ldots,4\tilde{N}} \lambda_k \tilde{S}_{lm}^{(s)}(k),
\]
\[
V_{l} = \sum_{k=1,\ldots,4\tilde{N}} \lambda_k \tilde{C}_{lm}^{(s)}(k), \quad V_{m} = \sum_{k=1,\ldots,4\tilde{N}} \lambda_k \tilde{S}_{lm}^{(s)}(k),
\]
\[
\tilde{C}_{lm}^{(s)}(k) = \sum_{k=1,\ldots,4\tilde{N}} \lambda_k \tilde{C}_{lm}^{(s)}(k), \quad \tilde{S}_{lm}^{(s)}(k) = \sum_{k=1,\ldots,4\tilde{N}} \lambda_k \tilde{S}_{lm}^{(s)}(k),
\]
\[
\tilde{C}_{lm}^{(s)} \in \langle \cos(\theta_{lm} - \delta_{lm} - \psi) \rangle^C,
\]
\[
\tilde{S}_{lm}^{(s)} \in \langle \sin(\theta_{lm} - \delta_{lm} - \psi) \rangle^S,
\]
\[
\lambda_{lm}^{\tilde{C}_{lm}^{(s)}} + \beta_{lm}^{\tilde{C}_{lm}^{(s)}} \in \langle \sin(\theta_{lm} + \delta_{lm} + \psi) \rangle^S,
\]
\[
- \beta_{lm}^{\tilde{C}_{lm}^{(s)}} + \alpha_{lm}^{\tilde{C}_{lm}^{(s)}} \in \langle \cos(\theta_{lm} + \delta_{lm} + \psi) \rangle^C,
\]
where the last four trigonometric envelope constraints correspond to (15)–(16).

Note that (17) precludes the need for the linking constraint (5r) that relates the common term \( V_{l}V_{m} \) in the products \( V_{l}V_{m} \sin(\theta_{lm}) \) and \( V_{l}V_{m} \cos(\theta_{lm}). \)

C. QC Relaxation of the Rotated OPF Problem

Replacing the squared and trilinear terms with the corresponding lifted variables in the rotated OPF formulation (12) results in our proposed “Rotated QC” (RQC) relaxation: [2]

\[
\min \ (12a)
\]
subject to \( (\forall i \in \mathcal{N}, \forall (l, m) \in \mathcal{L}) \)
\[
\tilde{P}_{i}^{\vartheta} - \tilde{P}_{i}^{\varphi} = (g_{sh,i} \cos(\psi) - b_{sh,i} \sin(\psi)) w_{ii} + \sum_{(l,m) \in \mathcal{L}, \ s.t. i = l} \tilde{P}_{lm} + \sum_{(l,m) \in \mathcal{L}, \ s.t. m = i} \tilde{P}_{ml},
\]
\[
\tilde{Q}_{i}^{\vartheta} - \tilde{Q}_{i}^{\varphi} = -(g_{sh,i} \sin(\psi) + b_{sh,i} \cos(\psi)) w_{ii} + \sum_{(l,m) \in \mathcal{L}, \ s.t. i = l} \tilde{Q}_{lm} + \sum_{(l,m) \in \mathcal{L}, \ s.t. m = i} \tilde{Q}_{ml},
\]
\[
\tilde{P}_{lm} = (Y_{lm} \cos(\delta_{lm} + \psi) - b_{c,lm}/2 \sin(\psi)) w_{lt} - Y_{lm} \tilde{c}_{lm},
\]
\[
\tilde{Q}_{lm} = -(Y_{lm} \sin(\delta_{lm} + \psi) + b_{c,lm}/2 \cos(\psi)) w_{lt} - Y_{lm} \tilde{s}_{lm},
\]
\[
\tilde{P}_{ml} = -Y_{lm} \tilde{c}_{lm} + (Y_{lm} \cos(\delta_{lm} + \psi) - b_{c,lm}/2 \sin(\psi)) w_{mm},
\]
\[
\tilde{Q}_{ml} = Y_{lm} \tilde{s}_{lm} - (Y_{lm} \sin(\delta_{lm} + \psi) + b_{c,lm}/2 \cos(\psi)) w_{mm},
\]
\[
\tilde{P}_{lm}^{2} + \tilde{Q}_{lm}^{2} \leq w_{ll} \tilde{\ell}_{lm},
\]
\[
\tilde{\ell}_{lm} = \left( b_{c,lm}^{2}/4 + Y_{lm}^{2} - Y_{lm} b_{c,lm} \cos(\delta_{lm} + \psi) \sin(\psi) \right) w_{ll} + Y_{lm}^{2} w_{mm}
\]
\[
+ Y_{lm} b_{c,lm} \sin(\delta_{lm} + \psi) \cos(\psi) \right) w_{ll} + Y_{lm}^{2} w_{mm}
\]
\[
+ \left( -2Y_{lm}^{2} \cos(\delta_{lm} + \psi) + Y_{lm} b_{c,lm} \sin(\psi) \right) \tilde{c}_{lm} + \left( 2Y_{lm}^{2} \sin(\delta_{lm} + \psi) + Y_{lm} b_{c,lm} \cos(\psi) \right) \tilde{s}_{lm},
\]
Equations (5h), (12d)–(12h), (17), (18).

D. Tightened QC Relaxation of the Rotated OPF Problem

Applying the angle sum and difference identities in combination with (14) reveals a linear relationship between the trigonometric functions used in the original QC relaxation (5), \( \cos(\theta_{lm}) \) and \( \sin(\theta_{lm}) \), and those in the RQC relaxation (18), \( \cos(\theta_{lm} - \delta_{lm} - \psi) \) and \( \sin(\theta_{lm} - \delta_{lm} - \psi) \):

\[
\begin{bmatrix}
\cos(\theta_{lm}) \\
\sin(\theta_{lm})
\end{bmatrix}
= M_{lm}
\begin{bmatrix}
\sin(\theta_{lm} + \delta_{lm} + \psi) \\
\cos(\theta_{lm} + \delta_{lm} + \psi)
\end{bmatrix}
= M_{lm}
\begin{bmatrix}
\sin(\theta_{lm} - \delta_{lm} - \psi) \\
\cos(\theta_{lm} - \delta_{lm} - \psi)
\end{bmatrix},
\]
where the constant matrix \( M_{lm} \) is defined as

\[
M_{lm} = \frac{1}{2}
\begin{bmatrix}
\sin(\delta_{lm} + \psi) & \cos(\delta_{lm} + \psi) \\
\cos(\delta_{lm} + \psi) & -\sin(\delta_{lm} + \psi)
\end{bmatrix}
= \begin{bmatrix}
\alpha_{lm} & \beta_{lm} \\
-\beta_{lm} & \alpha_{lm}
\end{bmatrix}
\]

with \( \alpha_{lm} \) and \( \beta_{lm} \) defined as in (14). As mentioned in Section V-A, the RQC relaxation (18) can be further tightened by additionally enforcing the envelopes \( \langle \cos(\theta_{lm}) \rangle^C \) and \( \langle \sin(\theta_{lm}) \rangle^S \) used in the original QC relaxation (5). This results in the “Tightened Rotated QC” (TRQC) relaxation:

\[
\min \ (12a)
\]
subject to \( (\forall i \in \mathcal{N}, \forall (l, m) \in \mathcal{L}) \)
\[
\tilde{C}_{lm}^{(s)} \in \langle \cos(\theta_{lm}) \rangle^C,
\]
\[
\tilde{S}_{lm}^{(s)} \in \langle \sin(\theta_{lm}) \rangle^S
\]

Equations (5h), (12d)–(12h), (17), (18d)–(18i).

E. An Empirical Analysis for Determining the Rotation \( \psi \)

The key parameter in our proposed QC formulation is the rotation \( \psi \). Choosing an appropriate value for \( \psi \) using an analytical method is challenging because, as shown in Fig. 1, \( \psi \) simultaneously affects the envelopes for both the sine and cosine functions such that values of \( \psi \) which lead to tighter envelopes for the cosine function can result in looser envelopes for the sine function (and vice-versa). Moreover, the single value for \( \psi \)
applied to the entire system requires balancing the impacts of $\psi$ among all lines simultaneously. Thus, choosing an appropriate value for $\psi$ is not straightforward. We therefore use the following empirical analysis to choose a value for $\psi$ that works well for a range of test cases. In our results, we denote the best value of $\psi$ for each case as $\psi^*$. 

Fig. 4 shows the optimality gaps for the PGLib-OPF test cases as a function of $\psi$, each normalized by the maximum gap for that case over all values for $\psi$. The results in the figure were generated by sweeping $\psi$ from $-90^\circ$ to $90^\circ$ in steps of $0.5^\circ$. (The figure is exactly symmetric for values of $\psi$ from $90^\circ$ to $-90^\circ$.) The shaded red bands around the median line (in black) show every fifth percentile of the results.

The results in Fig. 4 indicate that good values of $\psi$ are consistent across the test systems. Thus, we suggest using $\psi = 80^\circ$, which is where the median of the optimality gaps over all the test cases was smallest. Moreover, the symmetry in Fig. 4 implies that selecting $\psi$ within the intervals $[-90^\circ, -80^\circ], [-15^\circ, -5^\circ]$, and $[80^\circ, 90^\circ]$ results in nearly the smallest optimality gaps for almost all of the test cases compared to the optimality gaps from the RQC relaxation using $\psi^*$. 

Our ongoing work is generalizing the rotated QC formulation proposed in this paper by allowing for different values of $\psi$ for each line in the system in order to construct tighter envelopes (i.e., independent choices of $\psi_{lm}$ for each $(l, m) \in \mathcal{L}$ rather than one value of $\psi$ for the entire system). While complicating the overall formulation, this generalization simplifies the impacts from choosing each $\psi_{lm}$ and thus has the potential to enable analytical methods for identifying the best values for $\psi_{lm}$ for each $(l, m) \in \mathcal{L}$. One possible approach is to compute the value of $\psi_{lm}$ that minimizes the areas of the envelopes (i.e., the yellow and red regions in Fig. 2).

VI. NUMERICAL RESULTS

This section demonstrates the effectiveness of the proposed approach using selected test cases from the PGLib-OPF v18.08 benchmark library [26]. These test cases were selected since existing relaxations fail to provide tight bounds on the best known objective values. Our implementations use Julia 0.6.4, JuMP v0.18 [27], PowerModels.jl [28], and Gurobi 8.0 as modeling tools and the solver. The results are computed using a laptop with an i7 1.80 GHz processor and 16 GB of RAM.

Table I summarizes the results from applying the QC (5), RQC (18), and TRQC (20) relaxations to selected test cases. The first column lists the test cases. The next group of columns represents optimality gaps, defined as

$$OptimalityGap = \frac{\text{LocalSolution} - \text{QCBound}}{\text{LocalSolution}}. \quad (21)$$

The optimality gaps are defined using the local solutions to the non-convex problem (1) from PowerModels.jl. The final group of columns shows the solver times.

Comparing the second and third columns in Table I reveals that using admittances in polar form without rotation (i.e., the RQC relaxation (18) with $\psi = 0$) can improve the optimality gaps of some test cases (e.g., improvements of 3.76% and 3.19% for “case30_ieee” and “case24_ieee_rts_api”, respectively, relative to the original QC relaxation (5)). However, the RQC relaxation with $\psi = 0$ has worse performance in other cases, such as “case300_ieee” and “case14_ieee_sad”, which have 0.02% and 2.29% larger optimality gaps, respectively.

Using a non-zero value for $\psi$ can improve the optimality gaps. Solving the RQC relaxation (18) with the suggested $\psi = 80^\circ$ obtained from the empirical analysis in Section V-E results in 1.08% better optimality gaps, on average, compared to the original QC relaxation. The RQC relaxation (18) with $\psi^*$ (the best value of $\psi$ for each case) provides optimality gaps that are not worse than those obtained by the original QC relaxation (5) for all test cases, yielding an improvement of 1.36% on average compared to the original QC relaxation. As one specific example, the gap from the original QC relaxation for “case162_ieee_dtc_sad” is 6.22% compared to 6.30% for the RQC relaxation (18) with $\psi = 0$ relaxation (18). Use of the suggested $\psi = 80^\circ$ reduces the gap to 5.65%, which is superior to the gap obtained from the QC relaxation (5). Using $\psi^*$ further reduces the optimality gap to 5.59%.

Enforcing the envelopes from both the original QC relaxation and the RQC relaxation, i.e., the TRQC relaxation (20), further improves the optimality gaps. Solving the TRQC relaxation (20) with the suggested $\psi = 80^\circ$ results in 1.29% better gaps, on average, compared to the original QC relaxation. The TRQC relaxation with $\psi^*$ yields optimality gaps that are 1.57% and 0.21% better, on average, compared to the original QC relaxation and the RQC relaxation with $\psi^*$. The additional envelopes $\langle \sin(\theta_{lm}) \rangle^S$ and $\langle \cos(\theta_{lm}) \rangle^C$ in the TRQC relaxation increase the average solver time by 22%.

Fig. 5 visualizes the optimality gaps for variants of the QC relaxation over a range of test cases. Positive values indicate an improvement in the optimality gap of the associated variant relative to the original QC relaxation (5). The test cases are sorted in order of increasing optimality gaps obtained from the original QC relaxation. The TRQC relaxation with $\psi^*$ achieves the smallest optimality gaps. While the RQC relaxation with $\psi = 0$ obtains a worse optimality gap for some test cases compared to the original QC relaxation, both the QC and TRQC relaxations with $\psi^*$ outperform the QC relaxation for all test cases. As expected from the analysis in Section V-E, applying

AC: AC local solution from (1), QC Gap: Optimality gap for the QC relaxation from (5), RQC Gap: Optimality gap for the Rotated QC relaxation from (18), TRQC Gap: Optimality gap for the Tightened Rotated QC Relaxation from (20), \(\psi^*\): Use of the best \(\psi\) for this case.

Fig. 5. Comparison of optimality gap differences with respect to the original QC relaxation (5) for different QC relaxation variants.

VII. CONCLUSION

This paper proposes and empirically tests two improvements for strengthening QC relaxations of OPF problems by tightening the envelopes used for the trigonometric terms. The first improvement represents the line admittances in polar form. The second improvement applies a complex base power normalization with angle \(\psi\) in order to rotate the arguments of the trigonometric terms. An empirical analysis is used to suggest a good value for \(\psi\). Comparison to the state-of-the-art QC relaxation reveals the effectiveness of the proposed improvements.

Our ongoing work is extending the RQC relaxation to allow for distinct values of \(\psi\) for each line.

Mohammad Rasoul Narimani (Member, IEEE) received the B.S. and M.S. degrees in electrical engineering from the Razi University and Shiraz University of Technology, respectively. He also received the Ph.D. degree in electrical engineering from the Missouri University of Science & Technology. His research interests are in the application of optimization techniques to electric power systems. He is a Postdoc at Texas A&M University, College Station.

Daniel K. Molzahn (Senior Member, IEEE) received the B.S., M.S., and Ph.D. degrees in electrical engineering and the masters of public affairs degree from the University of Wisconsin–Madison, where he was a National Science Foundation Graduate Research Fellow. He is an Assistant Professor with the School of Electrical and Computer Engineering at the Georgia Institute of Technology. He also holds an appointment as a Computational Engineer in the Energy Systems Division at Argonne National Laboratory and is a Fellow of the Strategic Energy Institute at Georgia Tech. He was a Dow Postdoctoral Fellow in sustainability at the University of Michigan, Ann Arbor. His research focuses on optimization and control of electric power systems.

Mariesa L. Crow (Fellow, IEEE) received the B.S.E. degree in electrical engineering from the University of Michigan and the Ph.D. degree in electrical engineering from the University of Illinois-Urbana/Champaign. She joined the Missouri University of Science & Technology in 1991. She is the Fred Finley Distinguished Professor Emeritus of electrical engineering at Missouri S&T. Her area of professional interest is computational methods and power electronics applications to renewable energy systems, microgrids, and energy storage. She is a Registered Professional Engineer in the State of Missouri.
