Abstract
The present work considers the damped Pinney equation, defined as the model arising when a linear in velocity damping term is included in the Pinney equation. In the general case, the resulting equation does not admit Lie point symmetries or reduction to a simpler form by any obvious coordinate transformation. In this context, the method of Kuzmak–Luke is applied to derive a perturbation solution, for weak damping and slow time dependence of the frequency function. The perturbative and numerical solutions are shown to be in good agreement. The results are applied to examine the time evolution of Gaussian-shaped wave functions in the Kostin formulation of dissipative quantum mechanics.

1. Introduction

As is well known, the Pinney equation [1] is ubiquitous in nonlinear dynamics. A partial list of applications includes the exact solution for the classical and quantum harmonic oscillators [2, 3], the search for invariants (constants of motion) [4–6], the stability analysis of charged particle motion in accelerators [7, 8], the propagation of gravitational waves [9], the amplitude-phase representation of quantum mechanics [10], the derivation of the Feynman propagator for variable-mass problems [11], numerical solutions for non-relativistic quantum problems [12], cosmological particle-creation models [13], cosmological models for the Friedmann–Robertson–Walker metric [14], isotropic, four-dimensional cosmological theories [15, 16], rotating shallow water-wave systems [17], curve flows in affine geometries [18], the stabilizer set of Virasoro orbits [19], Bose–Einstein condensates with time-dependent traps and/or time-dependent scattering length [20, 21], discretized Pinney models [22, 23] and nonlinear oscillations of transversally isotropic hyperelastic tubes [24].

However, in spite of such a large number of applications, the Pinney equation in itself does not have any dissipation term. Hence, it is natural to generalize the model by inclusion of the simplest damping mechanism, a term linear in the velocity. We call the resulting model the damped Pinney equation. As discussed in more detail in section 5, damped Pinney equations arise in quantum mechanical models with dissipation. Specifically the Kostin formulation [25] of the non-conservative quantum time-dependent harmonic oscillator admits an exact Gaussian solution in terms of the solutions of a damped Pinney equation [26]. A damped Pinney equation also comes for Kostin’s dissipative quantum mechanics under an arbitrary potential, after an expansion in the neighborhood of the classical path [27]. In addition, the Pauli equation for the Aharonov–Bohm effect with a time-dependent mass particle also reduces to a damped Pinney equation [28].

There is a close relation between the solutions of the time-dependent harmonic oscillator and of the Pinney equation, see the nonlinear superposition law (2) in section 2. At first sight, one can expect some simple connection between the solutions of the damped harmonic oscillator and damped Pinney equations. However, as is shown in the following, this relationship, if existing, is nontrivial. Additional difficulties arise from the non-existence of a useful obvious point or non-local transformations removing the
damping term and casting the damped Pinney equation into some well-known integrable class of equations. Reduction to Abel or Emden–Fowler equations can be shown to be trivial, but this does not help us very much in solving the original problem. Indeed such classes of equations can be integrated only in some particular cases but not for the general damped Pinney equation. Finally, the symmetry structure of the damped Pinney equation is poor in comparison to the three-parameter group, SL(2, R), always admitted by the usual Pinney equation. These issues are discussed in more detail in section 2.

In view of the above difficulties, the present work is dedicated to the modest task of providing an approximate solution for the damped Pinney equation, assuming weak damping. In addition, a slow variation of the frequency function is allowed. The perturbation technique chosen is the method of Kuzmak–Luke \cite{29–31}, which is appropriate to generate bounded solutions for strongly nonlinear oscillator equations. Afterwards the perturbative solution is applied to dissipative quantum mechanics in Kostin’s version. A damped Pinney equation appears naturally in this formulation of dissipative quantum systems.

This work is organized as follows. In section 2, the damped Pinney equation is presented and some of its basic properties are discussed. In section 3, the Kuzmak–Luke method is applied to derive a perturbative solution, free from secular divergences. Section 4 shows good agreement of the approximate solution with some numerical examples. In section 5, the general connection between the damped Pinney equation and the dissipative quantum mechanics is explored. The final section is dedicated to conclusions.

2. The damped Pinney model

As is well known \cite{1}, the general solution for the Pinney equation

$$\dot{x} + \omega^2(t)x = \frac{k}{x^3},$$ \hspace{1cm} (1)

where \(\omega = \omega(t)\) is a time-dependent frequency function and \(k\) a numerical constant, can be written as

$$x = (c_1 \sigma_1^2 + c_2 \sigma_2^2 + 2c_3 \sigma_1 \sigma_2)^{1/2},$$ \hspace{1cm} (2)

where \(c_1, c_2\) and \(c_3\) are constants such that \(c_1 c_2 - c_3^2 = k\) and \(\sigma_1, \sigma_2\) are solutions for the time-dependent harmonic oscillator equation,

$$\ddot{\sigma}_i + \omega^2(t)\sigma_i = 0, \quad i = 1, 2, 3,$$ \hspace{1cm} (3)

with unit Wronskian, \(\sigma_1 \sigma_2 - \sigma_2 \sigma_1 = 1\). We restrict \(k\) to be positive to prevent ‘collapse into the origin’ issues. Notice the differences to the quantum case, where the wave function for the time-dependent singular harmonic oscillator is regular provided \(k > -\hbar^2/(4m^2)\), restoring dimensional quantities \cite{32}. However, in the formal classical limit, setting \(\hbar \equiv 0\) we strictly need \(k > 0\) to avoid \(x\) collapsing to the origin. This can be verified e.g. from the solution shown in equation (2) or from the potential function associated with equation (1), namely \(V = \omega^2 x^2/2 + k/(2x^2)\) which is not bounded from below if \(k < 0\). As a particular example for \(\omega = 1\) and initial conditions \(x(0) = 1, \dot{x}(0) = 0\), equation (2) gives \(x^2 = \cos^2 t + k \sin^2 t\). Therefore one would have \(x = 0\) at some time \(t = t_0 > 0\) for any \(k \leq 0\).

Equation (1) does not include any mechanism for dissipation. In this context, it is natural to add a term linear in the velocity, yielding the damped Pinney equation

$$\dot{x} + 2c \dot{x} + \omega^2(t)x = \frac{k}{x^3},$$ \hspace{1cm} (4)

where \(c > 0\) is a constant positive parameter. Note that a time dependence of the damping coefficient easily could be easily removed by an appropriate change of coordinates. Hence the basic properties of the system are already displayed for a constant \(c\).

Unlike the undamped (\(c \equiv 0\)) case, the integration of equation (4) is a challenge in general. Indeed equation (4) does not possess a universal Lie point symmetry group for an arbitrary frequency function. This is in contrast to the richer sl(2, R) algebra always admitted by the usual Pinney equation \cite{33} for any choice of \(\omega(t)\). It can be shown that the damped Pinney equation has geometric symmetries for particular functional dependencies of \(\omega(t)\), but these special cases are outside the scope of the present work. Also the application of symmetry generators, which are quadratic in the velocity, does not produce new results. Actually, a coordinate transformation puts equation (4) into the form of a generalized Emden–Fowler equation of index \(-3\). There is an extensive literature on the integrability of generalized Emden–Fowler equations of arbitrary index \cite{34,35}, but we believe that it is still interesting to investigate in more detail the index \(n = -3\) case.

There is no easily identifiable point transformation, so that the damped Pinney equation could be put into a simpler, always integrable form. As a tentative example, consider the quasi-invariance transform

$$x = \rho(t) Q(T), \quad T = T(t),$$ \hspace{1cm} (5)

where \(Q\) is the new dependent variable and \(\rho\) and \(T\) are functions of time to be determined according to convenience. The resulting equation is given by

$$\rho \ddot{T} + \frac{d^2 Q}{dT^2} + (\rho \ddot{\rho} + 2 \dot{\rho} \dot{T} + 2 \dot{\rho} \dot{T} + 2 \dot{\rho} \dot{T}) \frac{dQ}{dT} + (\dot{\rho} + \omega^2 \rho) Q = \frac{k}{\rho^3 Q^3}.$$ \hspace{1cm} (6)

From equation (6), it is easy to verify that it is not possible simultaneously to eliminate the damping term and set the coefficient of the inverse cubic term to a constant.

Indeed the damping term in equation (6) can be eliminated provided

$$\ddot{T} = \frac{\rho \ddot{\rho}}{\rho^2},$$ \hspace{1cm} (7)

ignoring an irrelevant multiplicative constant that could be included. By use of equations (6) and (7) we derive

$$\frac{\dot{Q}^2}{Q^2} + W^2 Q = \frac{k e^{\dot{\rho} t}}{Q^3},$$ \hspace{1cm} (8)

where \(W = W(t)\) is a function of time, defined in terms of the auxiliary equation

$$\dot{\rho} + 2 \dot{\rho} \dot{\rho} + \omega^2 \rho = \frac{W^2 e^{-\dot{\rho} t}}{\rho^3}.$$ \hspace{1cm} (9)
One can choose $W = \text{constant}$ or even $W = 0$, but in all cases equation (8) would still be explicitly time dependent through the inverse cubic term, since $\epsilon \neq 0$ and $k$ is assumed constant. The non-autonomous character of equation (8) prevents solvability in general. The time dependence should be written using $t = t(T)$, obtained via equation (7).

At least, setting $W \equiv 0$, one can cast the problem in the form of a generalized Emden–Fowler equation of index $-3$,

$$\frac{d^2 Q}{dT^2} = \mu(T) \frac{Q}{Q^3},$$  

(10)

where $\mu(T) = k \exp(4\epsilon t)$. This is equivalent to a choice of gauge [34]. However, from the practical point of view of computing the solution, this property is not very helpful. Consider the simplest case of a constant frequency function $\omega = \omega_0$. Since $\omega = 0$, it is trivial to solve equation (9) assuming $W = 0$. Using equation (7) and the particular solution $\rho = \exp(-\epsilon t) \cos[\sqrt{\omega_0^2 - \epsilon^2} t]$, equation (8) becomes

$$\frac{d^2 Q}{dT^2} = k \exp\left(\frac{4\epsilon}{\sqrt{\omega_0^2 - \gamma^2}} \tan^{-1}\left[\sqrt{\omega_0^2 - \gamma^2} T \right]\right).$$  

(11)

Equation (11) does not fall into any of the known integrable Emden–Fowler equations [35, 36]. Evidently, trying different particular solutions for equation (9) does not improve the scenario.

For time-dependent frequencies, the same procedure applies, but the resulting Emden–Fowler equation could be even more complicated. In the undamped ($\epsilon \equiv 0$) case, equation (11) reduces to the Ermakov–Pinney equation [1, 4], the integrability of which is well known. Also, in general, the non-autonomous Emden–Fowler equation of index $-3$ does not possess the Painlevé property. For instance, Conte [34] and Govinder and Leach [35] consider only the situation in which $\mu$ is a constant. In addition, there is no quadratic constant of motion for equation (4), except in the autonomous case [34].

A detailed analysis shows that the damped Pinney equation does not match the Tresse–Cartan conditions [37, 38] and hence is not linearizable through a general point transformation. Also, generalized Sundman transformations $Q = Q(x,t)$, $dT = F(x,t) dt$ and $F \partial Q / \partial x \neq 0$ can be shown to be useless. Indeed the damped Pinney equation does not match the conditions established in [39, 40] in order to be reduced to the free particle or similar simple equations via generalized Sundman transformations.

Another avenue could be the reduction to an Abel equation of the second kind through $v \equiv v(x) = \dot{x}$, so that

$$\frac{dv}{dx} = -2\epsilon v - \omega^2 x + \frac{k}{x^3}.$$  

(12)

However, equation (12) does not correspond to any of the known integrable Abel equations [41–43]. Also certain classes of non-local symmetries are not helpful, see equation (5.10) of [44]. The difficulties are due to the singular $\sim x^{-3}$ term.

Some Pinney equations with time-dependent damping and nonlinear terms have been considered in the literature, e.g. in the calculation of the geometric phases and angles of dynamical systems. Specifically [45] these modified Pinney equations are given by

$$\ddot{x} - \frac{m}{m} \dot{x} + \omega^2 x = \frac{k m^2}{x^3},$$  

(13)

where $m$, which can be interpreted as a time-dependent mass, and $\omega$ are arbitrary functions of time and $k$ is a constant. Note that in equation (13) the form of the time dependence allows the use of

$$Q = \frac{x}{\sqrt{m \rho}}, \quad T = \int \frac{dt}{\rho^2},$$  

(14)

where $\rho$ is an arbitrary function of time, to convert equation (13) to a Pinney equation in a standard form,

$$\frac{d^2 Q}{dT^2} + \rho^3 \left[\dot{\rho} + \left(\omega^2 + \frac{\dot{m}}{2m} - \frac{3m^2}{4m^2}\right) \rho\right] Q = \frac{k}{3 \rho}.$$  

(15)

Therefore these systems are somewhat trivial. Note the particular form of the nonlinear term, which needs to be proportional to $m^2$ so that the scaling (14) works. From a physical point of view, the most relevant case would be the one in which the nonlinear term is time independent. In addition, other different classes of generalized Pinney models with nonlinear and time-dependent damping have been discussed elsewhere [46]. The conclusion of the section is that apparently damped Pinney equations in form (4) do not possess a closed-form solution valid for general $\omega(t)$, unlike the standard Pinney equation. The same applies to the alternative form given by equation (10) for arbitrary $\mu(t)$.

3. Approximate solution for weak damping and slow time dependence

The difficulties enumerated in the last section suggest the use of perturbation theory, in the case of weak damping. In other words, we restrict to a small damping coefficient, $\epsilon$. An approximate solution would be welcome for physical applications as shown in section 4. In this work, this modest goal of deriving an approximate solution is achieved through the method of Kuzmak–Luke [29–31], which is good enough for equations that remain nonlinear even when the perturbation parameter goes to zero. Indeed this is the case of equation (4) when $\epsilon \to 0$. In addition, the Kuzmak–Luke technique applies only for slowly varying non-autonomous systems. Therefore, we consider general frequency functions of the form

$$\omega = \Omega(\epsilon t),$$  

(16)

so that the time dependence is slow. In equation (16), $\Omega$ is an arbitrary analytic function of its argument. To avoid some singularities, it is assumed that $\Omega > 0$. Fortunately, equation (4) in the non-perturbed ($\epsilon \equiv 0$) case has a periodic solution so that all conditions to apply the Kuzmak–Luke method are satisfied. The naive perturbation theory would lead to a divergent solution.

Other methods of removal of the divergences in the perturbation series, like the Lindstedt–Poincaré approach, could also be chosen. However, we verified that the insistence on the use of such variational methods just adds unnecessary
technical problems, even observing that equation (4) admits the Lagrange function
\[
L = L(x, \dot{x}, t) = \frac{e^{2yt}}{2} \left( k^2 - \omega^2 x^2 - \frac{k}{\chi^2} \right). \tag{17}
\]
In practice, it can be checked that the Kuzmak–Luke method is among the simplest reliable approaches for the problem.

The Kuzmak–Luke procedure seeks a series solution
\[
x = x_0(\tau, \tilde{t}) + \epsilon x_1(\tau, \tilde{t}) + \cdots, \tag{18}
\]
where \( \tilde{t} = \epsilon t \) and
\[
\frac{dr}{d\tilde{t}} = f(\tilde{t}), \tag{19}
\]
with \( f = f(\tilde{t}) \) determined by the requirement that \( x_0 \) be periodic in \( \tau \) with a constant period that can be taken as \( 2\pi \) without loss of generality. In the calculations, \( \tau \) and \( \tilde{t} \) are regarded as independent variables.

To zeroth order in \( \epsilon \),
\[
f^2(\tilde{t}) \frac{\partial^2 x_0}{\partial \tau^2} + \Omega^2(\tilde{t})x_0 = \frac{k}{x_0^2}, \tag{20}
\]
with no damping terms. Equation (20) can be integrated once so that we obtain the slowly varying energy function
\[
E_0 = E_0(\tilde{t}) = \frac{f^2}{2} \left( \frac{\partial x_0}{\partial \tau} \right)^2 + \frac{\Omega^2(\tilde{t})x_0^2}{2} + \frac{k}{2x_0^2}. \tag{21}
\]
The energy integral can be used to derive the quadrature
\[
x_0 = \pm \left[ \left( \frac{k}{\Omega^2(\tilde{t})} + A^2(\tilde{t}) \right)^{1/2} + A^2(\tilde{t}) \cos \left( \frac{2\Omega(\tilde{t})\tau}{f(\tilde{t})} + \phi(\tilde{t}) \right) \right]^{1/2}, \tag{22}
\]
where the slowly varying amplitude \( A = A(\tilde{t}) \) and phase \( \phi = \phi(\tilde{t}) \) are chosen according to convenience. For simplicity, we ignore the time dependence of the phase, setting \( \phi = \text{constant} \).

In terms of the amplitude the energy is \( E_0 = \Omega \sqrt{\Omega^2 A^2 + k} \), reproducing the usual law \( E_0 \sim A^2 \) in the linear (\( k \equiv 0 \)) case. From now we adopt the positive sign in equation (22).

By inspection, the trajectories defined by equation (22) become periodic with period \( 2\pi \), independent of \( \tilde{t} \), if we define
\[
f(\tilde{t}) = 2\Omega(\tilde{t}). \tag{23}
\]
We should determine \( A^2(\tilde{t}) \) requiring the first-order correction \( x_1 \) to be a periodic function of \( \tau \), free from mixed secular terms. In the present case, this can be shown to be equivalent to
\[
\exp(2\tilde{t}) \int_0^{2\pi} d\tilde{t} \left( E_0(\tilde{t}) - \frac{\Omega^2(\tilde{t})x_0^2(\tau, \tilde{t})}{2} - \frac{k}{2x_0^2(\tau, \tilde{t})} \right) = \text{constant}, \tag{24}
\]
where the integration is performed for fixed \( \tilde{t} \). For more details see for instance equation (3.6.35a) of [29]. Equation (24) gives
\[
A^2 = \frac{\sqrt{2\Omega_0} A_0 \exp(-\tilde{t})}{\Omega(\tilde{t})} \left( \sqrt{k} + \frac{\Omega_0 A^2_0 \exp(-2\tilde{t})}{4} \right)^{1/2}, \tag{25}
\]
where \( \Omega_0 \equiv \Omega(0) \) and \( A_0 \) is a reference value.

Finally, the combination of equations (22), (23) and (25) gives the zeroth-order solution
\[
x_0 = \frac{1}{\sqrt{\Omega(\epsilon \tilde{t})}} \left[ \sqrt{k} + \frac{\Omega_0 A^2_0}{2} e^{-2\epsilon \tilde{t}} + \frac{\sqrt{2\Omega_0} A_0 e^{-\epsilon \tilde{t}} \left( \sqrt{k} + \frac{\Omega_0 A^2_0}{4} e^{-2\epsilon \tilde{t}} \right)^{1/2}}{\sqrt{2}} \times \cos \left( 2 \int_0^{\epsilon \tilde{t}} \Omega(\epsilon t') dt' \right) \right]^{1/2}, \tag{26}
\]
containing the two constants of integration \( A_0 > 0 \) and \( \Omega_0 \). The perturbation procedure could be carried out to higher orders, but equation (26) is sufficient for our purposes.

The relevance of equation (26) cannot be overstated. It provides a sort of Jeffreys-Wentzel-Kramers-Billouin (JWKB) solution for the damped Pinney equation, reproducing the qualitative properties which are expected, namely, it shows a periodic motion spiraling toward the slowly varying ‘fixed’ point \( k^{1/4}/\Omega^{1/2}(\epsilon \tilde{t}) \). In addition, it can be checked that \( x_0 > 0 \) for all times provided \( k > 0 \).

When there is no damping (\( \epsilon \to 0 \) or nonlinearity \( k \to 0 \)), we derive \( x_0 \to A_0 \cos[\Omega_0(\tau - t_0)] \) as it should be. One can adopt the simplistic viewpoint that a numerical solution could be sufficient so that expression (26) is irrelevant. This naive criticism does not appreciate the usefulness of exact or approximate analytical solutions in general. However, it is clear that expressions like (26) provide information not so easily found from numerics, as, for instance, the functional dependence of the solutions on the amplitude \( A_0 \).

If there were no damping, but the frequency could still depend on \( \tilde{t} \), equation (26) would be replaced by
\[
x_0 = \frac{1}{\sqrt{\Omega(\epsilon \tilde{t})}} \left[ \sqrt{k} + \frac{\Omega_0 A^2_0}{2} + \frac{\sqrt{2\Omega_0} A_0}{\sqrt{4}} \left( \sqrt{k} + \frac{\Omega_0 A^2_0}{4} \right)^{1/2} \times \cos \left( 2 \int_0^{\epsilon \tilde{t}} \Omega(\epsilon t') dt' \right) \right]^{1/2}. \tag{27}
\]
This is the form arising from the well-known exact solution (2) of the standard Pinney equation, considering the JWKB solutions \( \sigma_1 = \Omega^{-1/2} \cos[\int \Omega dt'] \) and \( \sigma_2 = \Omega^{-1/2} \sin[\int \Omega dt'] \) for the time-dependent harmonic oscillator along with appropriate parameters \( c_i \). The powerfulness of both equations (26) and (27) is in their generality: they provide approximate solutions for the damped or standard Pinney equations, irrespective of the functional form of the frequency, as long as it is slowly varying and positive. Near singular times, at which \( \Omega = 0 \), the solutions would clearly not be appropriate.

It is interesting to observe that
\[
E_0 = \Omega \left( \frac{\Omega_0 A^2_0 e^{-2\epsilon \tilde{t}}}{2} + \sqrt{k} \right), \tag{28}
\]
as follows from equations (21) and (26), generalizing the usual adiabatic theorem to the damped and nonlinear case. It is also consistent with the asymptotic approaching toward the ‘fixed’ point \( k^{1/4}/\Omega^{1/2} \), where \( E_0 = \Omega \sqrt{k} \).
4. Simple examples

We have compared the approximate solution (26) with numerical simulations for specific frequency functions as follows.

4.1. $\Omega = \Omega_0$

For a constant frequency, $\Omega = \Omega_0$, it is expected that the trajectory approaches the value $k^{1/4}/\Omega_0^{3/2}$. Figure 1 shows the perturbative solution (26) for the parameters $\epsilon = 0.1$, $\Omega_0 = k = 1$, $A_0 = 2$ and $t_0 = 0$. For the parameters, one found $x_0(0) = 2.41$ and $x_0(0) = -0.17$. Simulation of the corresponding damped Pinney equation with these initial conditions fully confirms the accuracy of the approximate solution with no noticeable difference to figure 1.

4.2. $\Omega = \Omega_0(1 + \epsilon^2 t^2)^{-1/2}$

For a decaying frequency, $\Omega = \Omega_0(1 + \epsilon^2 t^2)^{-1/2}$, the trajectory shows the asymptotic behavior $x_0 \rightarrow \Omega_0^{-1/2}k^{1/4}(1 + \epsilon^2 t^2)^{1/4}$ because the confining potential becomes weaker. Figure 2 shows the perturbative solution (26) for the same parameters as in figure 1. There is no need to show the numerical simulation, because it gives the same result as figure 2.

4.3. $\Omega = \Omega_0(1 + \epsilon^2 t^2)^{1/2}$

When the frequency grows as $\Omega = \Omega_0(1 + \epsilon^2 t^2)^{1/2}$, the trajectory shows the asymptotic behavior $x_0 \rightarrow \Omega_0^{-1/2}k^{1/4}(1 + \epsilon^2 t^2)^{-1/4}$ because the confining potential becomes stronger. This is shown in figure 3 with the same parameters as before. It reproduces very well the numerical simulation.

To conclude the section, we have verified that the perturbation and numerical solutions disagree in the case of strong damping as can be expected.

5. Application to dissipative quantum mechanics

A popular approach for the time-dependent dissipative quantum harmonic oscillator is given by Kostin’s model [25], which is expressed in terms of the Kostin equation

$$\frac{\hbar^2}{2m} \frac{\partial^2 \psi}{\partial q^2} + \frac{m \omega^2(t) q^2}{2} + \frac{\hbar \epsilon}{i} \ln \left( \frac{\psi}{\psi^*} \right) \psi = i \hbar \frac{\partial \psi}{\partial t}.$$  \hspace{1cm} (29)

In equation (29), $\epsilon$ is the damping coefficient and the remaining symbols have their usual meaning. In particular, the wave function is $\psi = \psi(q, t)$. The Kostin nonlinear modification of the Schrödinger equation is among the only reliable alternatives to include damping in quantum mechanics, due to its smooth classical limit [47]. In particular, it is better than considering non-Hermitian terms in the Hamiltonian since a continuity equation follows from equation (29).

Consider the de Broglie–Bohm decomposition $\psi = \sqrt{n(q, T)} \exp(iS(q, t)/\hbar)$, assuming the Gaussian Ansatz

$$n = \left( \pi x^2(t) \right)^{-1/2} \exp \left( - \left( \frac{q - q_d(t)}{x(t)} \right)^2 \right).$$  \hspace{1cm} (30)
where \( x = x(t) \) and \( q = q_{cl}(t) \) are functions to be determined and the quantum-mechanical fluid velocity is

\[
 u(q, t) = \frac{1}{m} \frac{\partial S}{\partial q} = \frac{\dot{x}}{x} (q - q_{cl}) + \dot{q}_{cl}. \tag{31}
\]

From the Kostin equation it follows [26] that

\[
 \ddot{x} + 2\epsilon \dot{x} + \omega^2(t) x = \frac{\hbar^2}{m^2 x^3}, \tag{32}
\]

\[
 \ddot{q}_{cl} + 2\epsilon \dot{q}_{cl} + \omega^2(t) q_{cl} = 0. \tag{33}
\]

Clearly \( x \) satisfies a damped Pinney equation and \( q_{cl} \) solves the classical Newton equation. The same equations can be derived for arbitrary nonlinear potentials, expanding around the classical trajectory [27]. Assuming weak damping and slowly varying frequencies, we can apply the results of section 3.

As an example consider the oscillating frequency

\[
 \omega = \Omega_0 (1 + \gamma \sin(2\epsilon t)), \tag{34}
\]

where \( \Omega_0 > 0 \) and \( 0 < \gamma < 1 \) are fixed parameters. Using the approximate solution (26) and numerically solving equation (33) with the initial condition \( q_{cl}(0) = 1 \) and \( \dot{q}_{cl}(0) = 0 \), we derive both the quantum fluid density and velocity fields from equations (30) and (31). The results are shown in figures 4 (the standard deviation of the wave packet), 5 (the particle density) and 6 (the velocity field at fixed position \( q = 0 \)). In these graphs, the parameters are \( \gamma = 0.7, \ h = m = \Omega_0 = 1, \ \epsilon = 0.1, \ A_0 = 4 \) and \( t_0 = 0 \). Other examples can be easily constructed as well.

6. Conclusion

This work derives an approximate solution for the autonomous damped Pinney equation for weak damping and slowly varying frequency using the Kuzmak–Luke method. The JWKB-like solution (26) reproduces with accuracy the numerical solutions of the model. Due to the usefulness of the Pinney equation in many areas of physics, mathematics and engineering, it would be relevant to derive general statements about the corresponding model when dissipation is present. In this context, the perturbation approach here is just a first essay. However, probably there is no closed-form solution for the damped Pinney equation, valid for arbitrary frequency functions, in contrast to the undamped case. Adopting the optimistic view that such a universal solution could be constructed, one can expect the need for more complex non-local mappings than the generalized Sundman transformations. As a by-product there would be further insight into fundamental questions about dissipative non-autonomous quantum mechanics. Up to now only special classes of damped Pinney equations or the equivalent Emden–Fowler equation (10) are known to be amenable to reduction of order. The interesting point about the expression (26) is that the frequency function is not of a particular form, except for having a slow time dependence and not becoming zero. More accurate results could be found extending the perturbation theory to higher orders.
