Abstract

In this paper, we show that the global monopole spacetime is one of the exact solutions of Einstein equations by means of the method treating the matter field as a non-linear sigma model, without the weak field approximation applied in the original derivation by Barriola and Vilenkin in 1989. Furthermore, we find the physical origin of the topological charge in the global monopole spacetime. Finally, we generalize the proposal which generates spacetime from thermodynamical laws to the case that spacetime with global monopole charge.

Keywords: global monopole spacetime; exact solution; topological charge; thermodynamics

PACS: 04.20.-q, 04.20.Jb

1. Introduction

The global monopole charge resulted from the breaking of global O(3) symmetry belongs to those eccentric objects like cosmic strings, domain walls and etc, and playing an important role in modern physics, see [1]. Generally speaking, the global monopole charge is one kind of topological defect which can be produced by the phase transition in the early universe. There were a series of important investigations about this kind of topic before. For instance, Harari and Loustò found that the gravitational potential of such topological defect is negative [2]; the same topic in the dS/AdS spacetime was explored in Ref. [3] and the scholars found that the gravitational potential can be either repulsive or attractive, depending on the value of the cosmological constant. In addition, a new class of cold stars called D-stars (defect stars) were proposed in Ref. [4–6] in which the authors argued that the theory has monopole solutions in the case that the matter field disappears. Besides, the global monopole charge has also been considered in cosmology, see Ref. [7–10] for more details. Moreover, the global monopole spacetime was first found by Barriola and Vilenkin in 1989 [11] in which this category of spacetime was derived by applying the weak field approximation.

In Ref. [12], the general bulk/boundary correspondence, a generalized version of the AdS/CFT correspondence, was proposed. In order to find the evidence to support their proposal, the authors put forward the...
thermodynamics on the bulk where the topological charge is constructed. However, it should be noted that the authors’ proposal of this new physical concept (namely the topological charge) was based on some mathematical tricks and the physical origin of the topological charge was missed in this proposal.

In this paper we prove that the global monopole spacetime is an exact solution of the Einstein equations if the matter field is applied as the free nonlinear sigma model which has been introduced in textbook\(^{[13]}\). Additionally, we show that our work can be applied to higher dimensional spacetime as well as another maximum symmetrical spacetime. Furthermore, the difficulties in Ref. \(^{[12]}\) are investigated in our work by showing that the physical background of the topological charge is the sigma model (either linear or non-linear one, depending on the topological structure of the spacetime), and this topological charge will be reconstructed in a more reasonable way inspired by Ref. \(^{[14]}\).

This paper is constructed as follows: in section 2, we will show our proposal to derive the global monopole spacetime exactly; in section 3, this proposal will be generalized to more general cases; we will discuss the thermodynamics of the global monopole spacetime in section 4 and a brief conclusion will be presented in section 5.

2. The topological charge as the non-linear sigma model

In this section, we show that the global monopole spacetime can be derived as an exact solution of Einstein equations if one applies the matter field as the non-linear sigma model. This section contains three parts, in part 1, the matter field is introduced; in part 2, a derivation of the global monopole spacetime is presented; in part 3, the general properties of the Lagrangian which could be applied to derive the global monopole spacetime are discussed.

2.1. The matter field

As discussed before, the matter field is considered as the non-linear sigma model and whose Lagrangian is

\[
L = -\frac{1}{2} \int (2 - \frac{\phi^b \phi^b}{\eta^2}) \nabla_\mu \phi^a \nabla^\mu \phi^a, \tag{1}
\]

where \(\eta\) is a constant and the set \(\phi^a, a = 1, 2, 3...N\) is a set of \(N\) real scalar fields. Also, the Latin letter "\(a\)" should be distinguished from the Greek letter "\(\mu\)" as the former is the inner index of the scalar fields and the later is the tensor index. It should be also noticed that the Einstein’s notation is applied for the Latin letters here.

Applying the variational principle

\[
\delta S = 0, \tag{2}
\]

then the EOM of the scalar field is

\[
\frac{\nabla_\mu (\phi^b \phi^b) \cdot \nabla^\mu \phi^a}{\eta^2} + (2 - \frac{\phi^b \phi^b}{\eta^2}) \cdot \nabla_\mu \nabla^\mu \phi^a = - \frac{(\nabla_\mu \phi^b \nabla^\mu \phi^b) \phi^a}{\eta^2}. \tag{3}
\]

The stress-energy tensor of the scalar field can be determined as

\[
T_{\mu\nu} = -\frac{2}{\sqrt{|g|}} \frac{\delta S_M}{\delta g^{\mu\nu}}, \tag{4}
\]
Following such definition, the topological charge of the global monopole spacetime can be calculated as 

$$T_{\mu\nu} = -\frac{g_{\mu\nu}}{2}(2 - \frac{\phi^b\phi^b}{\eta^2})\nabla_\lambda \phi^a \nabla^\lambda \phi^a + (2 - \frac{\phi^b\phi^b}{\eta^2})\nabla_\mu \phi^a \nabla^\nu \phi^a.$$  

(5)

2.2. Derivation of the global monopole spacetime

The metric ansatz we apply here is

$$ds^2 = -f(r)dt^2 + h(r)dr^2 + r^2 d\theta^2 + r^2 \sin^2 \theta d\varphi^2,$$

(6)

where $f(r)$ and $h(r)$ are both just functions of the variable $r$. In such ansatz, the non-vanishing components of the Einstein tensor are

\[
\begin{align*}
G_{00} &= \frac{f(r)(h(r)^2 + rh(r)' - h(r))}{h(r)^2 r^2}, \\
G_{11} &= \frac{f(r) + rf(r)' - f(r)h(r)}{f(r)r^2}, \\
G_{22} &= \frac{rf(r)[rf(r)'h(r)' - 2h(r)(f(r)' + rf(r)'')]}{4f(r)^2 h(r)^2} \\
&\quad - \frac{rf(r)[rf(r)'h(r)' - 2h(r)(f(r)' + rf(r)'')]}{4f(r)^2 h(r)^2}, \\
G_{33} &= \frac{-r \sin^2 \theta(h(r)rf(r)'^2 + 2h(r)^2 f(r)')}{4f(r)^2 h(r)^2} \\
&\quad - \frac{f(r)[rf(r)'h(r)' - 2h(r)(f(r)' + rf(r)'')]}{4f(r)^2 h(r)^2}.
\end{align*}
\]

(7)

By applying the Einstein equations

$$G_{\mu\nu} = 8\pi G_n T_{\mu\nu},$$

(8)

and the EOM of the scalar field $\phi^a$, one can find the solutions are

$$f(r) = h(r)^{-1} = 1 - 8\pi G n^2 \frac{2MG}{r},$$

$$\phi^1 = \eta \sin \theta \cos \phi, \phi^2 = \eta \sin \theta \sin \phi, \phi^3 = \eta \cos \theta,$$

(9)

so the geometrical structure of the spacetime is obtained as

$$ds^2 = -(1 - 8\pi G n^2 \frac{2MG}{r}) dt^2 + \frac{1}{1 - 8\pi G n^2 \frac{2MG}{r}} dr^2$$

$$+ r^2 d\theta^2 + r^2 \sin^2 \theta d\varphi^2.$$  

(10)

Thus the global monopole solution is derived strictly.

Furthermore, inspired by Ref. [14] the topological charge of this spacetime can be constructed as

$$\tilde{Q} = \frac{1}{8\pi} \int \epsilon_{a_1 a_2 a_3} \phi^{a_1} d(\phi^{a_2}) \wedge d(\phi^{a_3}).$$

(11)

Following such definition, the topological charge of the global monopole spacetime can be calculated as $\eta^3$.

2.3. Lagrangian that can be used to derive the global spacetime

In this subsection, we would like to discuss a class of Lagrangian which could be used to derive the global monopole spacetime. To begin with, we choose the ansatz for the Lagrangian as following

$$L = -\frac{1}{2} F(\phi^b \phi^b) \nabla_\mu \phi^a \nabla^\mu \phi^a - V(\phi^a \phi^a).$$

(12)
Then one can obtain the energy-stress tensor as

\[ T_{\mu\nu} = F \nabla_\mu \phi^a \nabla_\nu \phi^a - g_{\mu\nu} \left( \frac{1}{2} F(\nabla_\lambda \phi^a \nabla^\lambda \phi^a) + V(\phi^a \phi^a) \right), \tag{13} \]

and the equation of motion (EOM) of the scalar field is

\[ F \nabla_\mu \nabla^a \phi^a + F' \nabla_\mu (\phi^a \phi^b) \nabla^a \phi^b = 2V' \phi^a + F'(\nabla_\mu \phi^b \nabla^a \phi^b) \phi^a, \tag{14} \]

in which \( F' \) donates that the functional \( F \) is varied by \( \phi^a \phi^a \).

By following \{Ref. [11]\}, we propose the ansatz of the scalar \( \phi^a \) as

\[ \phi^a = \eta g(r) \frac{\hat{x}_a}{r}, \tag{15} \]

where \( g(r) \) is a function of \( r \). In their paper, the authors required that \( g(r) \approx 1 \) while \( r \to \infty \). However, in our discussion here, we would like to find the conditions that \( g(r) \) could be equal to 1 exactly, so the expression of the scalar field could be obtained as following

\[ \phi^1 = \eta \sin \theta \cos \varphi, \quad \phi^2 = \eta \sin \theta \sin \varphi, \quad \phi^3 = \eta \cos \theta. \tag{16} \]

To attain such aim, we should first consider the global monopole spacetime, namely eq. (10). In such metric, the non-vanishing components of the Einstein tensor could be calculated as following,

\[ G_{00} = \frac{(1 - 8\pi G \eta^2 - \frac{2GM}{r})}{r^2}, \quad G_{11} = -\frac{8\pi G \eta^2}{r^2 - 8\pi G \eta^2 r^2 - 2GMr}. \tag{17} \]

Besides, the non-vanishing components of the energy-stress tensor are

\[ T_{00} = -(\frac{V(\eta^2) r^2 + 2F(\eta^2) \eta^2}{2r^3}) - \frac{2GM + 8\pi G \eta^2 r - r}{2}, \]
\[ T_{11} = \frac{V(\eta^2) r^2 + 2F(\eta^2) \eta^2}{4GMr - 2r^2 + 16\pi G \eta^2 r^2}, \]
\[ T_{22} = \frac{-V(\eta^2) r^2}{2}, \]
\[ T_{33} = -\frac{1}{2} V(\eta^2) r^2 \sin^2 \theta. \tag{18} \]

By comparing the equations together, one can find that once the conditions listed as the following was satisfied, the Einstein equations could be verified,

\[ V(\eta^2) = 0, F(\eta^2) = 1. \tag{19} \]

Furthermore, the scalar field should satisfy to the EOM (14). By applying the results of Eq. (16) to Eq. (14), one can obtain the EOM as

\[ -\frac{2}{r^2} \phi^a = 2V'(\eta^2) \phi^a + F'(\eta^2) \frac{2\eta^2}{r^2} \phi^a. \tag{20} \]

As discussed above, we have \( V(\eta^2) = 0 \), so \( V'(\eta^2) \) must be independent of the variable \( r \). So one can obtain that,

\[ V'(\eta^2) = 0, \quad F'(\eta^2) = -\frac{1}{\eta^2}. \tag{21} \]

To conclude this section, we claim that once the non-linear model satisfies to the conditions listed in eqs. (19), (21), it could be used to derived the global monopole spacetime.
3. The generalization of the derivation

In this section, the method proposed above is generalized to more general cases. Firstly, it will be applied to higher dimensional spacetime, and secondly, other classes of symmetrical spacetime with the global monopole charge will be derived.

3.1. The spherically symmetric case

In this case, the metric ansatz of the $n$ dimensional spacetime is

$$ds^2 = -f(r)dt^2 + h(r)dr^2 + r^2d\Omega_{n-2},$$

where $\Omega_{n-2}$ represents the $n - 2$ dimensional sphere. With some complicated calculations, one can verify that the non-vanishing components of Einstein tensor are

$$G_{00} = \frac{f(r)[(n-2)(n-3)h(r)^2 + (n-2)rh(r)']}{2h(r)^2r^2}$$

$$- \frac{(n-2)(n-3)f(r)}{2h(r)r^2},$$

$$G_{11} = \frac{(n-2)[(n-3)f(r) + rf(r)' - (n-3)f(r)h(r)]}{2f(r)r^2},$$

$$G_{ii} = \frac{g_{ii}}{4f(r)^2h(r)^2r^2} \left( f(r)r^2(2h(r))(n-3)f(r)' + rf(r)'' \right)$$

$$- rf(r)'h(r)' - h(r)f(r)'^2 r^2$$

$$- 2(n-3)(n-4)f(r)^2h(r)^2 - h(r)$$

$$- 2(n-3)f(r)^2rh(r)' \right),$$

where $g_{ii}$ is the components of the reduce metric of the $n - 2$ dimensional sphere.

Besides, the matter field applied here is still the non-linear scalar field, meaning that Eq.(5) can be also applied here. Combining the EOM of the scalar field (3) and the Einstein equations (8), one can solve the equations as

$$ds^2 = - \left( 1 - \frac{2G_nM}{r^{n-3}} - \frac{8\pi G_n\eta^2}{n-3} \right)dt^2$$

$$+ \frac{1}{1 - \frac{2G_nM}{r^{n-3}} - \frac{8\pi G_n\eta^2}{n-3}}dr^2 + r^2d\Omega_{n-2},$$

and

$$\phi^1 = \eta \cos \theta_1,$$

$$\phi^2 = \eta \sin \theta_1 \cos \theta_2,$$

$$\cdot$$

$$\cdot$$

$$\phi^{n-2} = \eta \sin \theta_1 \sin \theta_2 \ldots \sin \theta_{n-2} \cos \theta_{n-1},$$

$$\phi^{n-1} = \eta \sin \theta_1 \sin \theta_2 \ldots \sin \theta_{n-2} \sin \theta_{n-1}.$$
Then the topological charge should be defined as
\[
\hat{Q} = \frac{1}{(n-2)!A_{n-2}} \int \epsilon_{a_1a_2...a_{n-1}} \phi^{a_1} d(\phi^{a_2}) \wedge ... \wedge d(\phi^{a_{n-1}}),
\]  
where \(A_{n-2}\) is the volume of the \(n - 2\) dimensional sphere in \(n\) dimensional spacetime
\[
A_{n-2} = \pi^{\frac{n-1}{2}} \frac{\Gamma\left(\frac{n+1}{2}\right)}{\Gamma\left(\frac{n-1}{2}\right)}.
\]

one can verify that the topological charge in the \(n\) dimensional spacetime is \(\eta^{n-1}\) by definition.

3.2. The plane-symmetric case

We derive the global monopole-like spacetime in the plane-symmetric case in this subsection. Firstly, we introduce the metric ansatz as
\[
ds^2 = -f(r)dt^2 + h(r)dr^2 + r^2 dx^i dx_i.
\]

Here Einstein’s notation is applied and the index \(i\) range is \(i = 2, 3, 4,...,n\). One can calculate the non-vanishing components of the Einstein tensor as following
\[
G_{00} = -\frac{(n-2)f(r)[(n-3)h(r) - rh(r)']}{{2h(r)^2r^2}},
\]
\[
G_{11} = \frac{(n-2)f(r)[(n-3)f(r) + rf(r)']}{{2f(r)r^2}},
\]
\[
G_{ii} = g_n \frac{f(r)r^2[(n-3)f(r) + f(r)'] - rf(r)'h(r)'}{{4f(r)^2h(r)^2r^2}} + g_n \frac{2(n-3)f(r)^2[(n-4)h(r) - rh(r)']}{{4f(r)^2h(r)^2r^2}} - g_n \frac{h(r)r^2f(r)'}{{4f(r)^2h(r)^2r^2}}.
\]

Besides, the matter field applied here is the linear sigma model, which is different from that in the spherically symmetric case, and its Lagrangian is
\[
L = \frac{1}{16\pi G} \int R - \frac{1}{2\eta^2} \int \nabla_\mu \phi^a \nabla^\mu \phi^a.
\]

By applying the variational principle again, the EOM of the scalar field can be obtained directly as
\[
\nabla_\mu \nabla^\mu \phi^a = 0,
\]
and the stress-energy tensor can be calculated as the following by using Eq.(4) again
\[
T_{\mu\nu} = g_{\mu\nu}(-\frac{1}{2} \nabla_\chi \phi^a \nabla^\chi \phi^a) + \nabla_\mu \phi^a \nabla_\nu \phi^a.
\]

So the general solution of the Einstein equations in this case is
\[
ds^2 = -\left(\frac{2G_n M}{r^{n-3}} - \frac{8\pi G_n \eta^2}{n-3}\right)dt^2 + \frac{1}{\frac{2G_n M}{r^{n-3}} - \frac{8\pi G_n \eta^2}{n-3}} dr^2 + r^2 dx^i dx_i,
\]
and the solutions of the scalar fields are
\[ \phi^1 = \eta x_2, \]
\[ \phi^2 = \eta x_3, \]
\[ \cdots \]
\[ \phi^{n-2} = \eta x_{n-1}. \] (34)

The topological charge is constructed as
\[ \tilde{Q} = \frac{1}{(n-2)!A_{n-2}} \int \epsilon_{a_1a_2 \ldots a_{n-2}} d(\phi^{a_1}) \wedge \cdots \wedge d(\phi^{a_{n-2}}), \] (35)
where \( A_{n-2} \) is the volume of a unit submanifold and the topological charge here is \( \eta^{n-2} \). We should mention that the plane-symmetric space is not compact, so in order to make the concept of 'topological charge' more rational, the technology of compactification should be applied here, and one can refer to Ref. [15,16] for more details. In this case, our result can match well with the topological charge proposed in Ref. [12]. Thus, the proposal of Ref. [12] is just one of our possible situations. Moreover, our calculation reveals that the physical origin of the topological charge is related to the global monopole charge, namely the sigma model exactly.

### 3.3. The hyperbolically symmetric case

We apply our proposal to hyperbolically symmetric case in this subsection, and the metric ansatz is
\[ ds^2 = -f(r)dt^2 + h(r)dr^2 + r^2d\theta^2 + r^2 \sinh^2 \Omega_{n-3}, \] (36)
with calculation, the non-vanishing components of the Einstein tensor are
\[ G_{00} = \frac{f(r)((n-2)rh(r)' - (n-2)(n-3)h(r)^2)}{2h(r)^2 r^2} - \frac{(n-2)(n-3)h(r)}{2h(r)^2 r^2}, \]
\[ G_{11} = \frac{(n-2)(n-3)f(r) + rf(r)'}{(2f(r)r^2)} - \frac{rf(r)'}{h(r)} - h(r)f(r)'' - h(r)[f(r)']^2 r^2 + 2(n-3)(n-4)f(r)^2 h(r)^2 + h(r)] - 2(n-3)f(r)^2 h(r)r', \] (37)

We argue that the matter field here is also the non-linear sigma model, which means that the Lagrangian (1) can still be applied in this case. However, it should be underscored that the space where the scalar fields live in is Minkowski space, namely the EOM of the scalar fields is
\[ \eta_{ad} \nabla_\mu (\phi^b \phi^d) \cdot \nabla^\mu \phi^a + \eta^2 (2 - \eta_{ad} \frac{\phi^b \phi^d}{\eta^2}) \cdot \nabla_\mu \nabla^\mu \phi^a \]
\[ = -\eta_{ad} \nabla_\mu \phi^b \nabla^\mu \phi^d \phi^a, \] (38)
and the stress-energy tensor is

\[ T_{\mu\nu} = - \frac{\eta}{2} \eta_{ac} (2 - \eta_{bd}) \eta^a \eta^b \eta^c \eta^d \nabla_\lambda \phi^a \nabla_\lambda \phi^b + \eta_{ac} (2 - \eta_{bd}) \eta^a \eta^b \nabla_\mu \phi^a \nabla_\nu \phi^b. \]

Using the Einstein equations (8) and the EOM of the scalar fields (38), one can obtain the spacetime structure

\[ ds^2 = - \left( 1 - \frac{2G_n M}{r^{n-3}} - \frac{8\pi G_n \eta^2}{n - 3} \right) dt^2 \]
\[ + \frac{1}{1 - \frac{2G_n M}{r^{n-3}} - \frac{8\pi G_n \eta^2}{n - 3}} dr^2 + r^2 d\theta^2 \]
\[ + r^2 \sinh^2 \theta \Omega_{n-3}, \]

and the solutions of the matter fields

\[ \phi^1 = \eta \cosh \theta_1, \]
\[ \phi^2 = \eta \sinh \theta_1 \cos \theta_2, \]
\[ ... \]
\[ \phi^{n-1} = \eta \sinh \theta_1 \sin \theta_2 \sin \theta_3 \cdots \sin \theta_{n-2} \cos \theta_{n-1}, \]
\[ \phi^n = \eta \sinh \theta_1 \sin \theta_2 \sin \theta_3 \cdots \sin \theta_{n-2} \sin \theta_{n-1}. \]

Indeed, one can construct the topological charge density in this case as

\[ Q = \frac{1}{(n-2)! A_{n-2}} \int \epsilon_{a_1 a_2 \ldots a_{n-2}} \phi^{a_1} d(\phi^{a_2}) \wedge \ldots \wedge d(\phi^{a_{n-1}}), \]

and the result is \( \eta^{n-1} \), and just like plane-symmetric case, compactification should be also applied here.

4. The thermodynamical properties of the global monopole spacetime

In Ref. [12], while the authors constructed the black hole thermodynamics with the topological charge in formula, it is interesting to investigate the matter field in the spacetime that play an important role in the thermodynamics. In our proposal, we suggest that the matter field is the sigma model, and for convenience, we propose the first law of thermodynamics in the plane case as

\[ dE = TdS - \frac{16\pi G_n \tilde{Q}^{\frac{4}{n-2}} S'}{A_{n-2}(n-2)^2(n-3)} d\tilde{Q}, \]

in which \( S \) is the entropy of the black hole, \( S = \frac{r_{\text{h}}^{n-3}}{4G_n} \), and \( S' \) denotes that the entropy \( S \) is derived by the variable \( r \). One point should be underscored here is that the power of the topological charge in our proposal of the first law of the thermodynamics is the same as that in the propose in Ref. [12], and the coefficient is chosen for convenience, implicating that our propose is reasonable. With some calculation, one can get the following equation

\[ dM + 4\pi \tilde{Q}^{\frac{4}{n-2}} \frac{n-3}{r_{\text{h}}^{n-3}} r_{\text{h}}^{n-3} d\tilde{Q} = TdS. \]
Here, it should be noted that there are two meanings of the symbol "$d$", namely if it acts on the variable of the spacetime, it stands for the normal differential, whereas if it acts on the global parameters, it means variation.

Indeed, there is a quasi-local version of such black hole thermodynamics, which is the so-called unified first law,

$$(dE)_a = A_{n-2}(\psi)_a + w(dV_{n-1})_a,$$

which was proposed in Ref. [17], and $V_{n-1} = \frac{A_{n-2}r^{n-1}}{n-1}$. Here $w$ is the work term, defined as the trace of the stress-energy in leading two dimensions, namely

$$w = -\frac{4\pi}{(n-2)A_{n-2}}(g^{tt}T_{tt} + g^{rr}T_{rr}),$$

and $\psi_a$ is known as the energy flux,

$$\psi^a = T^{ab}\nabla_b r + w\nabla^a r.$$  

In the quasi-local version of thermodynamics, the quasi-local energy $E$ can be defined as the so-called Misner-Sharp energy

$$E_{ms} = \frac{r^{n-3}}{2G_n}(k - g^{rr}),$$

see Ref. [18–20]. In our discussion, the value is

$$E_{ms} = M + \frac{4\pi \tilde{Q}^{n-2}}{n-3} r^{n-3},$$

varying it, one has

$$dE_{ms} = dM + \frac{4\pi \tilde{Q}^{n-2}}{(n-2)(n-3)} d\tilde{Q} + 4\pi \tilde{Q}^{n-2} r^{n-4} dr,$$

comparing this with Eq.(44), we can get the unified first law in this case as

$$dE_{ms} = T dS + 4\pi \tilde{Q}^{n-2} r^{n-4} dr,$$

it should be noted that the global monopole charge plays a significant role in the quasi-local version of the spacetime thermodynamics.

Besides, there are a series of works which generate the spacetime construction from thermodynamics by using the unified law and treating the spacetime as an adiabatic system Ref. [21–23]. These works can be summarized as follow: one can derive the structure of the spacetime once there is a work term defined by Eq.(46). However, there is a great limitation in these works: the authors only applied this method to the spacetime with the maximum symmetry. So the problem is raised naturally: could such method be applied to more general situations?

Indeed, there was a try before. In Ref. [24], the authors put forward a similar method by using the Komar mass and the ADM mass, rather than the Misner-Sharp mass to generate spacetime from thermodynamics. In that work, the authors applied their proposal to the global monopole spacetime successfully. However, when they generated the global monopole spacetime some subtle trick was applied, which may cause argument.

Here, we argue that the original method can be applied to the spacetime with the global charge exactly. We consider the plane case firstly and choose the metric ansatz for convenience as

$$ds^2 = -f(r)dt^2 + \frac{1}{h(r)} dr^2 + r^2 dx_i dx^i.$$  

9
In this case, the Misner-Sharp energy can be calculated as
\[ E_{\text{ms}} = -\frac{r^{n-3}}{2G_n} h(r), \] (53)
we can use the unified first law in a adiabatic condition to derive \( h(r) \). According to Eq. (51), we can get the equation of \( h(r) \) as follow,
\[-\frac{1}{2G_n} [(n - 3)h(r)r^{n-4} + h(r)'r^{n-3}]dr = 4\pi \tilde{Q} \frac{4\pi}{(n-3)} r^{n-4}dr. \] (54)
The solution of this differential equation is
\[ h(r) = -\frac{2G_n M}{r^{n-3}} - \frac{8\pi G_n \eta^2}{n-3}. \] (55)
Here "M" is the integration constant, known as the ADM mass.

Our next task is to find \( f(r) \). To do this we need to apply the so-called geometric surface gravity, which was proposed in Ref. [17] firstly and generalized to higher dimensional spacetime in Ref. [22], defined as follow
\[ \kappa_G = (n - 3) G_n \frac{E_{\text{ms}}}{r^{n-2}} - A_{n-2} G_n rw. \] (56)
In the topic we discuss here, the work term \( w \) is
\[ w = \frac{4\pi \eta^2}{A_{n-2} r^2}. \] (57)
So the geometric surface gravity can be calculated as
\[ \kappa_G = \frac{(n - 3)G_n M}{r^{n-2}}. \] (58)
The traditional surface gravity is defined as
\[ \kappa = \frac{h(r)}{2f(r)} f(r)', \] (59)
by following the previous works, we assume that the surface gravity is equal to the geometric surface gravity, thus
\[ \frac{h(r)}{2f(r)} f(r)' = \frac{(n - 3)G_n M}{r^{n-2}}, \] (60)
by solving the equation, we have
\[ f(r) = -\frac{2G_n M}{r^{n-3}} - \frac{8\pi G_n \eta^2}{n-3}. \] (61)
So the metric can be derived as
\[ ds^2 = -(r^{n-3}) \left( -\frac{2G_n M}{r^{n-3}} - \frac{8\pi G_n \eta^2}{n-3} \right) dt^2 + \frac{1}{(n-3)G_n M - \frac{8\pi G_n \eta^2}{n-3}} dr^2 + r^2 dx_i dx^i. \] (62)
Furthermore, the previous discussion can be applied to the global monopole spacetime. However, in this situation, the thermodynamics of the spacetime with topological charge should be redefined as
\[ dM + \frac{4\pi \tilde{Q}^{n-4} r^{n-3}}{(n-1)(n-3)} d\tilde{Q} = TdS. \] (63)
On the other hand, the Misner-Sharp energy is
\[ E_{ms} = M + \frac{4\pi \tilde{Q}^2}{n-3} r^{n-3}, \] \hfill (64)
and the unified first law is
\[ dE_{ms} = TdS + 4\pi \tilde{Q}^2 r^{n-4} dr. \] \hfill (65)

Using the same method proposed above, one can get the global monopole solution
\[ ds^2 = - \left( 1 - \frac{2G_n M}{r^{n-3}} - \frac{8\pi G_n \eta^2}{n-3} \right) dt^2 + \frac{1}{1 - \frac{2G_n M}{r^{n-3}} - \frac{8\pi G_n \eta^2}{n-3}} dr^2 + r^2 d\Omega_{n-2}. \] \hfill (66)

The same discussion can be applied to the hyperbolic symmetrical case directly.

5. Discussion and Conclusion

The global monopole spacetime was first presented in Ref. [11], in which the matter field is treated as an approximate one. Thus, one of our works is deriving this spacetime exactly and revealing that the matter field which can be used to derive this spacetime is the non-linear sigma model. Moreover, the derivation is also generalized to higher dimensional spacetime \((n > 4)\) and the spacetime with other class of symmetry, namely the plane symmetry and the hyperbolic symmetry. The plane-symmetric case was proposed in Ref. [25], where the matter field is applied as a charged complex scalar field. Nevertheless, in our work we find that the linear sigma model can also be used to derive the same spacetime structure. Exactly, a similar idea which argues that the matter field of the global monopole spacetime is a sigma model was first proposed in Ref. [26]. However, it should be mentioned that in such paper, the author just gave us a very simple claim without any detail in such discussion. Moreover, in their proposal, the authors only focused on the spherically symmetric case in four dimensional spacetime. Thus we believe that our work makes an improvement in such aspect of research.

Our another work is that we reconstruct the topological charge which was first proposed in Ref. [12]. We find that the physical origin of the topological charge is the sigma model (both the linear one and the non-linear one). Moreover, our result can match the original proposal well in the plane-symmetric case, so it could be claimed that our work is an apposite generalization of the construction in Ref. [12].

Moreover, we investigate the thermodynamics of the spacetime by applying Misner-Sharp energy in our discussion, and then we construct the unified first law for this class of spacetime. Additional, we propose that the global monopole spacetime can be generated from the unified first law.
