Joint Optimization of STAR-RIS Assisted UAV Communication Systems
Qin Zhang, Yang Zhao, Hai Li, Member, IEEE, Shujuan Hou, and Zhengyu Song, Member, IEEE

Abstract—In this letter, we study the simultaneously transmitting and reflecting reconfigurable intelligent surface (STAR-RIS) assisted unmanned aerial vehicle (UAV) communications. Our goal is to maximize the sum rate of all users by jointly optimizing the STAR-RIS’s beamforming vectors, the UAV’s trajectory and power allocation. We decompose the formulated non-convex problem into three subproblems and solve them alternately to obtain the solution. Simulations show that: 1) the STAR-RIS achieves a higher sum rate than traditional RIS; 2) to exploit the benefits of STAR-RIS, the UAV’s trajectory is closer to STAR-RIS than that of RIS; 3) the energy splitting for reflection and transmission highly depends on the real-time trajectory of UAV.

Index Terms—Reconfigurable intelligent surface, simultaneous transmission and reflection, unmanned aerial vehicle, passive beamforming, trajectory design, power allocation.

I. INTRODUCTION

RECENTLY, the reconfigurable intelligent surface (RIS) has been considered as an emerging technology for future wireless communications [1]. However, the RIS is only able to reflect the incident signals, which means it can only achieve half-space coverage. To overcome this drawback, a novel concept of simultaneously transmitting and reflecting RIS (STAR-RIS) has been proposed [2], [3]. Different from the traditional RIS, the scattering elements of the STAR-RIS can reflect and transmit the incident signals at the same time, and thus achieve full-space coverage. More importantly, the STAR-RIS provides extra degrees-of-freedom (DoFs) by manipulating both the transmitting and reflecting signals [4].

Since the STAR-RIS offers more advantages than traditional RIS, there have been several studies on the STAR-RIS assisted communications [4], [5], [6], [7], [8]. In [4], three typical operating protocols for STAR-RIS were introduced, and the superiority of STAR-RIS over RIS was revealed by simulations. In [5], the sum rate maximization problem for STAR-RIS-NOMA systems was studied by jointly optimizing the decoding order, power allocation, and passive beamforming at the STAR-RIS. Focusing on the power consumption minimization problem, the beamforming of base station and STAR-RIS were jointly optimized for a STAR-RIS aided communication system in [6]. Besides, in [7], [8], a more practical model with coupled transmitting and reflecting coefficients was considered to study the resource allocation in STAR-RIS-aided networks.

In recent years, the RIS assisted UAV communications have been intensively studied [9], [10], [11], where the UAV’s trajectory, RIS’s passive beamforming and/or active beamforming at the UAV were jointly optimized. Despite the benefits of STAR-RIS, there has been no work focusing on the interplay between STAR-RIS and UAV communications, where the coupled UAV’s trajectory and STAR-RIS’s transmission/reflection coefficient require careful design. In addition, the potential performance gain brought by STAR-RIS in UAV communications is still unknown. Motivated by these observations, in this letter, a novel STAR-RIS assisted UAV communication framework is proposed. We aim to maximize the sum rate of all users by jointly optimizing the STAR-RIS’s beamforming vectors, the UAV’s trajectory, and power allocation. To address the formulated non-convex problem, we decompose it into three subproblems and solve them alternately to obtain the solution. Simulations show that STAR-RIS can achieve higher sum rate than RIS. Besides, compared to the trajectory with the deployment of RIS, the UAV’s trajectory with STAR-RIS is closer to the location of STAR-RIS in order to fully exploit the extra DoFs and acquire larger channel gains. More interestingly, the energy splitting for reflection and transmission modes highly depends on the real-time trajectory of UAV.

II. SYSTEM MODEL AND PROBLEM FORMULATION

A. System Model

As illustrated in Fig. 1, we consider a STAR-RIS assisted UAV communication system, consisting of one rotary wing UAV, one STAR-RIS, and K ground users, where all users can access the UAV by NOMA. The UAV flies at a fixed altitude of H. The flight time is decomposed into N equal time slots with sufficiently small slot length. Then the horizontal position of the UAV can be expressed by \( N + 1 \) points in the two-dimensional plane, which is denoted by \( q_n = [x_n, y_n]^T \in \mathbb{R}^{2 \times 1}, \forall n \in \{1, 2, \ldots, N + 1\} \). The mobility constraints of the UAV are \( q_1 = q_0^0, q_{N+1} = q_{N+1}^0 \) and \( \|q_{n+1} - q_n\|^2 \leq D^2 \), where \( q_1^0 \) and \( q_{N+1}^0 \) represent the initial and final locations of the UAV, and \( D \) represents the maximum distance that the UAV can move within a time slot.

We assume that the STAR-RIS is deployed at a fixed height of \( z_R \), equipped with \( M \) passive elements, and the horizontal position of the first element is denoted by \( \omega_R = [x_R, y_R]^T \in \mathbb{R}^{2 \times 1} \). There are \( R \) and \( T \) users in the reflection and transmission spaces of the STAR-RIS, respectively, and \( R + T = K \). Also, the location of the \( k \)-th user is
expressed as \( \omega_k = [x_k, y_k]^T \in \mathbb{R}^{2 \times 1}, \forall k \in \{1, 2, \ldots, K\} \). Consider the STAR-RIS works in the energy splitting (ES) mode, i.e., the energy of the signal incident on each element is split into the energies of transmitted and reflected signals [6]. Let

\[
\mathbf{u}_k^p = [\sqrt{\beta_{1n}^p}e^{j\theta_{1n}^p}, \sqrt{\beta_{2n}^p}e^{j\theta_{2n}^p}, \ldots, \sqrt{\beta_{Mn}^p}e^{j\theta_{Mn}^p}]^H \in \mathbb{C}^{M \times 1}
\]

be the reflection (\( p = r \)) or transmission (\( p = t \)) beamforming vectors of the \( m \)-th element at time slot \( n \), and the corresponding diagonal matrix is denoted by \( \Phi_n^p = \text{diag}(\mathbf{u}_n^p) \in \mathbb{C}^{M \times M} \), where \( \{\beta_{mn}^p, \theta_{mn}^p \in [0, 1]\} \) and \( \{\beta_{mn}^r, \theta_{mn}^r \in [0, 2\pi]\} \) denote the amplitudes and phase shifts of the reflection and transmission coefficients for the \( m \)-th element at time slot \( n \), respectively. Meanwhile, according to the energy conservation law, \( \beta_{mn}^r + \beta_{mn}^t = 1, \forall m \in \{1, \ldots, M\}, \forall n \in \{1, \ldots, N\} \), should be satisfied.

We assume the perfect channel state information (CSI) of all channels is available at the UAV, and the optimized transmission strategy can be exchanged among the STAR-RIS, UAV and ground users by a dedicated control channel. As shown in Fig. 1, since the STAR-RIS is generally deployed to assist transmissions where the line-of-sight (LoS) links are blocked by obstacles, the direct link from the UAV to each ground user is a Rayleigh fading channel [9]. Therefore, the channel vector of the UAV to user \( k \) at time slot \( n \) is

\[
\mathbf{h}_{kn}^{\text{ur}} = \frac{\xi}{d_{kn}^{\text{ur}}} \tilde{h}_{kn}^{\text{ur}},
\]

where \( \xi \) is the path loss at a reference distance of 1 meter, \( d_{kn}^{\text{ur}} = \sqrt{H^2 + ||\mathbf{q}_n - \mathbf{w}_k||^2} \) denotes the distance between the UAV and the \( k \)-th user at the \( n \)-th time slot, \( \xi \) represents the path loss exponent, and \( \tilde{h}_{kn}^{\text{ur}} \) is complex Gaussian random variable with zero mean and unit variance.

The transmission link from the UAV to STAR-RIS and from the STAR-RIS to ground users are assumed to be LoS channels. Therefore, at the \( n \)-th time slot, the channel vector of the UAV-STARRIS link is given by

\[
\mathbf{g}_n^{ur} = \sqrt{\frac{\xi}{d_{kn}^{ur}}} \bigl[1, e^{-j \frac{2\pi}{\lambda} d_{kn}^{ur}}, \ldots, e^{-j \frac{2\pi}{\lambda} (M-1) d_{kn}^{ur}}\bigr]^T,
\]

where \( d_{kn}^{ur} = \sqrt{(H - z_p)^2 + ||\mathbf{q}_n - \mathbf{w}_k||^2} \) denotes the distance between the UAV and the STAR-RIS at the \( n \)-th time slot, \( \xi \) represents the corresponding path loss exponent, and \( \varphi_{kn}^{ur} = \frac{2\pi}{\lambda} d_{kn}^{ur} \) is the cosine of the angle of arrival (AoA) of the signal. And we define \( \Theta_n = [1, e^{-j \frac{2\pi}{\lambda} d_{kn}^{ur}}, \ldots, e^{-j \frac{2\pi}{\lambda} (M-1) d_{kn}^{ur}}]^T \).

Similarly, the channel vector of the STAR-RIS to the \( k \)-th ground user is given by

\[
\mathbf{g}_k^{rg} = \sqrt{\frac{\xi}{d_{kn}^{rg}}} \bigl[1, e^{-j \frac{2\pi}{\lambda} d_{kn}^{rg}}, \ldots, e^{-j \frac{2\pi}{\lambda} (M-1) d_{kn}^{rg}}\bigr]^T,
\]

where \( d_{kn}^{rg} = \sqrt{R^2 + ||\mathbf{w}_R - \mathbf{w}_k||^2} \) denotes the distance between the STAR-RIS and the \( k \)-th user, \( \xi \) represents the path loss exponent, and \( \varphi_{kn}^{rg} = \frac{2\pi}{\lambda} d_{kn}^{rg} \) is the cosine of the angle of departure (AoD) of the signal to the \( k \)-th ground user.

Therefore, at the \( n \)-th time slot, the combined channel vector from the UAV to ground user \( k \) can be expressed as

\[
g_{kn} = h_{kn}^{\text{ur}} + (g_k^{rg})^H \Phi_n^{ur} g_{kn}^{ur}.
\]

For NOMA systems, the successive interference cancellation (SIC) is adopted by ground users to decode their own signals. Unfortunately, there are as many as \( K! \) decoding orders for \( K \) users, and the decoding order is highly coupled with STAR-RIS’s beamforming vector design [12]. In order to reduce the complexity, we assume the decoding order has been predetermined, which is from user 1 to \( K \). As a result, the condition \( |g_{Kn}|^2 \geq |g_{(K-1)n}|^2 \geq \cdots \geq |g_{1n}|^2 \) should be satisfied. Besides, \( p_{1n} \geq \cdots \geq p_{(K-1)n} \geq p_{Kn} \geq 0 \) is used to ensure the fairness among users, where \( p_{kn} \) denotes the transmission power allocated by the UAV to user \( k \) at time slot \( n \). Thus, at time slot \( n \), the date rate of user \( k \) is

\[
R_{kn} = \log_2 \left( 1 + \frac{p_{kn}|g_{kn}|^2}{\sum_{i=k+1}^{K} p_{in}|g_{in}|^2 + \sigma^2} \right).
\]

B. Problem Formulation

Let \( Q = \{q_n, \forall n\} \) denote the UAV’s trajectory, \( U = \{u_n^p, \forall n, \forall p \in \{t, r\}\} \) indicate the beamforming vectors of the STAR-RIS, and \( P = \{p_{kn}, \forall k, \forall n\} \) represent the power allocation. In this letter, our goal is to maximize the sum rate of all users by jointly optimizing \( Q, U \) and \( P \). Therefore, the optimization problem can be formulated as

\[
\mathcal{P} : \max_{Q,U,P} \sum_{n=1}^{N} \sum_{k=1}^{K} R_{kn}
\]

subject to

\[
q_1 = 0, q_{n+1} = q_{n+1}, \quad \forall n \geq 0
\]

\[
|q_{n+1} - q_n|^2 \leq D^2, \forall n,
\]

\[
\beta_{mn}^r, \beta_{mn}^t \in [0, 1], \forall m, \forall n
\]

\[
\varphi_{mn}^{ur}, \varphi_{mn}^{rg} \in [0, 2\pi], \forall m, \forall n
\]

\[
\varphi_{mn}^{ur} + \varphi_{mn}^{rg} = 1, \forall m, \forall n
\]

\[
\sum_{k=1}^{K} p_{kn} \leq P_{\text{max}}, \forall n
\]

\[
|g_{Kn}|^2 \geq |g_{(K-1)n}|^2 \geq \cdots \geq |g_{1n}|^2, \forall n
\]

\[
p_{1n} \geq \cdots \geq p_{(K-1)n} \geq p_{Kn} \geq 0, \forall n
\]

where \( P_{\text{max}} \) is the maximum transmit power of the UAV.

III. PROPOSED ALGORITHM

Problem \( \mathcal{P} \) is difficult to solve because of the coupled variables and non-convex constraints. Therefore, we decompose \( \mathcal{P} \) into three subproblems, where the STAR-RIS’s beamforming vectors, the UAV’s trajectory and power allocation are optimized, respectively.

A. STAR-RIS’s Beamforming Vectors Optimization

When the UAV’s trajectory \( Q \) and the power allocation \( P \) are fixed, problem \( \mathcal{P} \) can be rewritten as

\[
\mathcal{P}1: \max_{U} \sum_{n=1}^{N} \sum_{k=1}^{K} R_{kn}
\]

subject to

\[
(6d), (6e), (6f), (6h).
\]
In order to solve $\mathcal{P}1$, we introduce the slack variables $A_{kn}$ and $B_{kn}$, where $1/A_{kn} = p_{kn} |g_{kn}|^2$ and $B_{kn} = \sum_{i=k+1}^N p_{in} |g_{kn}|^2 + \sigma^2$. Thus, the achievable rate of user $k$ at time slot $n$ can be given by

$$R_{kn} = \log_2 \left(1 + \frac{1}{A_{kn} B_{kn}}\right).$$

Define $v_{kn} = [(g^p_{kn})^H \text{diag}(g^u_{kn}), h^u_{kn}], V_{kn} = v_{kn}^H v_{kn}$, $e_{kn} = u_{kn}^2$ and $E_{kn} = e_{kn}^p v_{kn}^H$, where $E_{kn}$ is the rank-1 constraint relaxation (SROCR) approach to obtain a rank-one constraint.

Then, problem $\mathcal{P}1$ can be transformed as

$$\mathcal{P}2: \max_{E_{kn}, A_{kn}, B_{kn}, R_{kn}} \sum_{n=1}^N \sum_{k=1}^K R_{kn}$$

s.t. \quad (6f),

$$\log_2 \left(1 + \frac{1}{A_{kn} B_{kn}}\right) \geq R_{kn},$$

$$\frac{1}{A_{kn}} \leq \text{Tr}(V_{kn} E_{kn}^p),$$

$$B_{kn} \geq \text{Tr}(V_{kn} E_{kn}^p) \sum_{i=k+1}^N p_{in} + \sigma^2.$$  

(9a)

(9b)

(9c)

(9d)

(9e)

However, the optimization problem is still non-convex due to constraint (9i). Therefore, we propose the sequential rank-one constraint relaxation (SROCR) approach to obtain a rank-one solution. Firstly, the non-convex constraint (9c) can be relaxed as [12]

$$\alpha(\tau_2) = \min \left(1, \frac{\varepsilon_{\max}(E_{kn}^p)}{\text{Tr}(E_{kn}^p)} + \Delta(\tau_2)\right),$$

where $\varepsilon_{\max}(E_{kn}^p)$ is the largest eigenvalue of $E_{kn}^p$, and $\alpha(\tau_2) \in [0, 1]$ is a relaxation parameter in the $\tau_2$-th iteration. And $\alpha(\tau_2)$ can be updated with the following formula [12]

$$\alpha(\tau_2) = \min \left(1, \frac{\varepsilon_{\max}(E_{kn}^p)}{\text{Tr}(E_{kn}^p)} + \Delta(\tau_2)\right).$$

where $\Delta(\tau_2)$ denotes the step size in the $\tau_2$-th iteration and needs to be resized according to the problem. Furthermore, since $\varepsilon_{\max}(E_{kn}^p)$ is non-differentiable, it can be approximated by the expression $\varepsilon_{\max}(E_{kn}^p) = e_{kn}^p \text{Tr}(E_{kn}^p)$, where $e_{kn}^p(\tau_2)$ denotes the eigenvector corresponding to the largest eigenvalue of $E_{kn}^p(\tau_2)$, and $E_{kn}^p(\tau_2)$ is the solution in the $\tau_2$-th iteration.

Finally, the STAR-RIS's beamforming vectors optimization problem can be approximated as

$$\mathcal{P}3: \max_{E_{kn}, A_{kn}, B_{kn}, R_{kn}} \sum_{n=1}^N \sum_{k=1}^K R_{kn}$$

s.t. \quad (6f), \quad (9i), \quad (9j), \quad (10),

$$e_{kn}^p(\tau_2) \geq \alpha(\tau_2) \text{Tr}(E_{kn}^p).$$

(13a)

(13b)

(13c)

Problem $\mathcal{P}3$ without the rank-one constraint (9i) is a standard convex semidefinite programming (SDP) problem [5], which can be effectively solved by standard solvers. Thus, the algorithm for solving $\mathcal{P}1$ can be summarized as Algorithm 1.

### Algorithm 1 for STAR-RIS's Beamforming Vectors Optimization

1. Initialize $U(0), \Delta(0)$ and the error tolerance $\nu$, and calculate $E_{kn}^{p(0)}$. Set $\alpha(0) = 0$ and the iterative index $\tau_2 = 0$.
2. **repeat**
3. Solve the problem (13) to optimize $E_{kn}^p$;
4. **if** problem (13) is solvable then
5. Update $E_{kn}^{p(\tau_2+1)} = E_{kn}^p, \Delta(\tau_2+1) = \Delta(\tau_2);
6. **else**
7. Update $E_{kn}^{p(\tau_2+1)} = E_{kn}^p(\tau_2), \Delta(\tau_2+1) = \Delta(\tau_2)$;
8. **end**
9. Update $\alpha(\tau_2)$ by (12), $\tau_2 = \tau_2 + 1$;
10. **until** $|1 - \alpha(\tau_2)| \leq \nu$ and the objective of (13) converges.
11. Obtain $E_{kn}^{p(\tau_2)}$, and return the optimal solution $U^*$.

**B. UAV’s Trajectory Optimization**

If the STAR-RIS’s beamforming vectors $U$ and the power allocation $P$ are given, problem $\mathcal{P}$ can be reformulated as

$$\mathcal{P}4: \max_Q \sum_{n=1}^N \sum_{k=1}^K R_{kn}$$

s.t. \quad (6b), \quad (6c), \quad (6h).$$

To maximize the sum rate of users, it is assumed that the phase alignment of the signals at the users can be achieved [9]. As such, $|g_{kn}|^2$ can be expressed as

$$|g_{kn}|^2 = C_{kn} \frac{d_{kn}^u}{d_{kn}^w} + F_{kn} \frac{d_{kn}^u}{d_{kn}^w} \alpha_{kn}^2 + C_{kn} \frac{d_{kn}^u}{d_{kn}^w} \alpha_{kn},$$

where $C_{kn} = \frac{\xi^2}{(d_{kn}^w)\alpha_{kn}}|\theta_{kn}^H| [\sqrt{\beta_{1n}}, \sqrt{\beta_{2n}}, \ldots, \sqrt{\beta_{Mn}}]^T$, $F_{kn} = \frac{2\xi^2/\alpha_{kn}}{(d_{kn}^w)\alpha_{kn}} \text{Re} \{\theta_{kn}^H (h_{kn}^u)^H [\sqrt{\beta_{1n}}, \sqrt{\beta_{2n}}, \ldots, V_{kn}^{u} \text{Tr}(E_{kn}^p) + \sigma^2.$$
Algorithm 2 Algorithm for UAV’s Trajectory Optimization

1. Initialize $Q^{(0)}$. Set the iterative index $\tau_3 = 0$ and the threshold value $\delta$.
2. repeat
3. Solve the problem (20) to optimize $Q$;
4. Update $Q^{(\tau_3+1)} = Q$, $\tau_3 = \tau_3 + 1$;
5. until the increase of the objective value is below $\delta$;
6. Return the optimal solution $Q^*$.

and problem $P4$ can be reformulated as

$$
\begin{align}
P_{5}^*: \max_{q_{kn}, \lambda_{kn}} & \sum_{n=1}^{N} \sum_{k=1}^{K} \log_2 \left( 1 + \frac{p_{kn}}{\sum_{n=1}^{N} \sum_{k=1}^{K} p_{kn} + \sigma^2 / S_{kn}} \right) \\
\text{s.t.} & \quad (6b), (6c), \\
& \quad l_n \geq \sqrt{(H - z_R)^2 + \|q_n - \omega R\|^2}, \\
& \quad j_{kn} \geq \sqrt{H^2 + \|q_n - \omega_k\|^2}, \\
& \quad S_{kn} \geq S_{(K-1)n} \geq \ldots \geq S_{1n},
\end{align}
$$

where $S_{kn} = C_{kn}^2 + (l_{kn})^2 + (j_{kn})^2 + G_{kn}$.

However, problem $P5$ is still non-convex. Therefore, at the given points $l_{(\tau_3)n}$ and $j_{(\tau_3)n}$, we derive the first-order Taylor expansions of (16a), $S_{kn}$, $l^{(\tau_3)n}$ and $j^{(\tau_3)n}$, respectively, and obtain

$$
\begin{align}
\log_2 \left( 1 + \frac{p_{kn}}{\sum_{n=1}^{N} \sum_{k=1}^{K} p_{kn} + \sigma^2 / S_{kn}} \right) & \geq \log_2 \left( 1 + \frac{p_{kn}}{\sum_{n=1}^{N} \sum_{k=1}^{K} p_{kn} + \sigma^2 / S_{(\tau_3)n}} \right) \\
& \quad - W_{(\tau_3)n}, \\
S_{kn} & \geq S_{(\tau_3)n} + G_{kn}, \\
l^{(\tau_3)n} & \geq l_{(\tau_3)n} - j_{(\tau_3)n} - j_{(\tau_3)n}, \\
j^{(\tau_3)n} & \geq l_{(\tau_3)n} + j_{(\tau_3)n} - j_{(\tau_3)n},
\end{align}
$$

where $W_{(\tau_3)n} = \frac{\sigma^2 q_{kn}}{2} \frac{l_{(\tau_3)n}^2}{(l_{(\tau_3)n})^2 + (j_{(\tau_3)n})^2}$, $G_{kn} = \frac{p_{kn}}{\sum_{n=1}^{N} \sum_{k=1}^{K} p_{kn} + \sigma^2 / S_{kn}}$, and $\tau_3$ denotes the iterative index.

Finally, the UAV’s trajectory optimization problem can be transformed as

$$
\begin{align}
P_{6}^*: \max_{q_{kn}, \lambda_{kn}} & \sum_{n=1}^{N} \sum_{k=1}^{K} \left( -l^{(\tau_3)n} - j^{(\tau_3)n} \right) \\
\text{s.t.} & \quad (6b), (6c), \\
& \quad O_{Kn} \geq O_{(K-1)n} \geq \ldots \geq O_{1n}, \\
& \quad (H - z_R)^2 + \|q_n - \omega R\|^2 + (l_{kn})^2 - 2l_{kn} l_n \leq 0, \\
& \quad H^2 + \|q_n - \omega_k\|^2 + (l_{kn})^2 - 2l_{kn} j_n \leq 0.
\end{align}
$$

Similarly, problem $P6$ is convex and can be solved efficiently by standard solvers such as CVX [9]. The proposed algorithm for solving problem $P4$ is shown in Algorithm 2.

C. Power Allocation Optimization

For the given UAV’s trajectory $Q$ and STAR-RIS’s beamforming vectors $U$, problem $P$ can be reformulated as

$$
\begin{align}
P_{7}^*: \max_{P} & \sum_{n=1}^{N} \sum_{k=1}^{K} R_{kn} \\
\text{s.t.} & \quad (6g), (6i).
\end{align}
$$

Let $\psi_{kn} = \sum_{k=1}^{K} P_{kn}$ and $\psi_{(k+1)n} = 0$. Considering the first-order Taylor expansion of $R_{kn}$ at the given point $\psi_{(k+1)n}$, we have

$$
\begin{align}
R_{kn} & \geq \psi_{kn} = \sum_{k=1}^{K} P_{kn}, \\
\psi_{(k+1)n} & \geq \psi_{kn} - \sum_{k=1}^{K} \frac{\partial R_{kn}}{\partial \psi_{kn}} |_{\psi_{kn}} (\psi_{kn} - \psi_{(k+1)n}), \\
\psi_{kn} & \leq \psi_{(k+1)n} + \sum_{k=1}^{K} \frac{\partial R_{kn}}{\partial \psi_{kn}} |_{\psi_{kn}} (\psi_{kn} - \psi_{(k+1)n}).
\end{align}
$$

It is easy to prove that the problem $P8$ is convex since it has a linear objective function and linear inequality constraints. After solving problem $P8$, the power allocation can be obtained by $P_{kn} = \psi_{kn}^* - \psi_{(k+1)n}^*$, $\forall k, n$. Then, the algorithm for solving problem $P7$ is summarized in Algorithm 3.

D. Joint Beamforming Vectors, Power Allocation, and Trajectory Optimization Algorithm

With the aid of Algorithms 1–3, the proposed algorithm to jointly optimize the STAR-RIS’s beamforming vectors, the UAV’s trajectory and power allocation is summarized in Algorithm 4. Since the objective value of problem $P$ is non-decreasing after each iteration, the proposed algorithm is guaranteed to converge [3].

IV. SIMULATION RESULTS

In the simulations, we consider one STAR-RIS deployed at the height of $z_R = 20$ m, and the first element is located at $\omega_R = [0, 0]^T$ m in a horizontal plane. For a fair comparison between STAR-RIS and RIS, one transmitting-only RIS and one reflecting-only RIS with M/2 elements are employed at the same location as STAR-RIS. Besides, the mode selection (MS) protocol for STAR-RIS is also considered for comparison [4]. The UAV flies at a fixed altitude $H = 30$ m, and its initial and final locations are $q_1^0 = [10, -250]^T$ m and $q_N^0 = [10, 250]^T$ m, respectively. The flight time of the UAV is decomposed into $N = 30$ time slots, and $P_{\text{max}} = 30$ dBm. The path loss exponents are $\alpha_1 = 3$, $\alpha_2 = 2$, and $\alpha_3 = 2.8$ [9].
Algorithm 4 Proposed Algorithm for Problem $\mathcal{P}$
1. Initialize $U^{(0)}$, $Q^{(0)}$, and $P^{(0)}$. Set the iterative index $\tau = 0$ and the threshold value $\delta''$.
2. repeat
3. Update $U^{(\tau+1)}$ via Algorithm 1 with $Q^{(\tau)}$ and $P^{(\tau)}$;
4. Update $Q^{(\tau+1)}$ via Algorithm 2 with $U^{(\tau+1)}$ and $P^{(\tau)}$;
5. Update $P^{(\tau+1)}$ via Algorithm 3 with $U^{(\tau+1)}$ and $Q^{(\tau+1)}$ and $\tau = \tau + 1$;
6. until the increase of the objective value is below $\delta''$.
7. Return the optimal solution $U^*$, $Q^*$, and $P^*$.

In Fig. 2(a), the sum rate of users versus the number of STAR-RIS’s elements is illustrated. It is found that with the assistance of STAR-RIS or RIS, the sum rate of users grows as the number of elements increases since more scattering elements bring higher beamforming gains at the users. More importantly, the STAR-RIS with ES outperforms the STAR-RIS with MS or traditional RIS. This is because the STAR-RIS for ES owns extra DoFs by splitting the energy of reflection and transmission for each element, while each element for MS can only operate in a binary mode, i.e., either in the reflection or in the transmission mode. The traditional RIS exhibits much worse performance as it can only reflect or transmit signals by a fixed number of elements.

Fig. 2(b) illustrates the trajectory of the UAV, where the users are located at both sides of STAR-RIS. It can be observed that the UAV always flies and serves users at the right side of STAR-RIS, i.e., a single STAR-RIS can achieve full-space coverage, while it is impossible for a transmitting/reflecting-only RIS. Besides, the UAV’s trajectory with STAR-RIS is closer to the location of STAR-RIS compared to that with RIS. This is because the STAR-RIS can provide extra DoFs to further improve channel conditions by flexible reflecting/transmitting energy splitting. Such an observation reveals the potential advantages of STAR-RIS again.

Fig. 2(c) presents the average amplitudes of the reflection and transmission coefficients of all elements in the STAR-RIS at different time slot. It can be seen that at the first and last several time slots, i.e., when the UAV is far away from STAR-RIS, the amplitudes of reflection coefficients are larger than that of transmission coefficients. This is because the long distance leads to poor channel conditions between UAV and STAR-RIS. Thus, more energy is allocated to the reflected signals to acquire higher sum rate as the users in reflection space are closer to the UAV and STAR-RIS. On the contrary, when the UAV is closer to STAR-RIS at the middle couple of time slots, better channel conditions between UAV and STAR-RIS can be obtained. Since there are more users in the transmission space, the STAR-RIS allocates more energy to the transmission mode in order to make better use of the passive beamforming gain and improve the sum rate of users.

V. CONCLUSION
In this letter, we studied the novel STAR-RIS assisted UAV communications, where the sum rate of all users was maximized by decomposing the formulated problem into three subproblems. Simulations showed that the STAR-RIS can achieve higher sum rate than traditional RIS owing to the extra DoFs. Moreover, the UAV’s trajectory was closer to STAR-RIS, and the energy splitting for reflection and transmission highly depended on the real-time trajectory of UAV.
