Abstract

**Background:** Several months into the COVID-19 pandemic, reassessing intensive care unit (ICU) utilization, specifically with regional impact on diverse populations, should be a priority for hospitals planning for critical care resource allocation. In our study, we reviewed the impact of COVID-19 on a community hospital serving an urban region, comparing the sociodemographic distribution of ICU admissions before and during the pandemic.

**Methods:** We executed a time sensitive analysis to see if COVID-19 ICU admissions reflect regional sociodemographic populations as well as ICU admission trends prior to the current pandemic. Collected sociodemographic variables included sex, race, ethnicity, and age of adult patients (age 18 and older) admitted to the hospital's medical and cardiac ICUs, which were converted to COVID-19 ICUs. The time period selected was 18-months, which was then dichotomized into pre-COVID-19 admissions (December 1, 2018 to March 13, 2020) and COVID-19 ICU admissions (March 14, 2020 to May 31, 2020). Variables were compared using Fisher’s exact tests and Wilcoxon tests when appropriate.

**Results:** During the 18-month period, 1861 patients were admitted to the aforementioned ICUs. The mean age of the 1861 patients was 62.75 ± 15.57 years old, with the majority of these patients being male (52.23%), White (64.43%), and non-Hispanic/Latinx (95.75%). There were differences in racial and ethnic distribution comparing pre-COVID-19 admissions to the COVID-19 admissions. Compared to pre-COVID-19 ICU admissions, there was an increase in African American versus White admissions (p=0.01) and an increase in Hispanic/Latinx versus non-Hispanic/Latinx admissions (p<0.01), during the COVID-19 pandemic.

**Discussion:** During the first three months of admissions to COVID-19 ICUs, there was a rise in admissions among Hispanic/Latinx and African-American patients, while non-Hispanic/Latinx and White patient admissions declined compared to the previous pre-COVID year. These findings support development of strategies to enhance allocation of resources to bolster novel, equitable strategies to mitigate the incidence of COVID-19 in minority populations.

Background

Optimizing the utilization of intensive care units (ICUs) is a significant healthcare priority in the United States. This optimization requires a critical understanding of variables that contribute to regional usage of adult ICUs. For instance, geographic and sociodemographic factors (e.g. prevalence of minority race and ethnicity, poverty, educational status)\(^2,3\) and the presence of certain medical conditions\(^4,5\) are associated with adult ICU utilization and admissions\(^5,6\). When assessing common diagnoses present on admission to adult medical ICUs, such as sepsis and acute respiratory distress syndrome (ARDS), these diagnoses cluster in regions with high prevalence of certain medical conditions (e.g. hypertension and diabetes)\(^7\) and with socioeconomic factors (e.g. race, ethnicity, poverty)\(^5,8\). Insight into the
aforementioned variables would ensure efficient use of critical care resources for hospitals, communities, and patients.

The current pandemic caused by the severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) has created unprecedented demands on acute health care, necessitating the development of triage algorithms typically assigned to battlefields to determine who receives medical treatment or access to medical equipment, and in which order. Specifically, SARS-CoV-2 resulting coronavirus infectious disease 2019 (COVID-19) frequently results in sepsis and ARDS, which warrant ICU admissions. Having reached a point several months into the pandemic, reassessing ICU utilization, specifically regional impact, should be a priority for hospitals in an effort to assist in ongoing public health policies to mitigate the spread of the virus as well as planning for critical care resource allocation.

In our study, we reviewed the impact of COVID-19 on a community hospital serving an urban region. Specifically, we executed a time sensitive analysis to determine if COVID-19 ICU admissions reflect regional sociodemographic populations as well as ICU admission trends prior to the current pandemic.

**Methods**

**Patient Population**

We obtained 18-months of admissions (December 2018 to May 2020) to the medical intensive care unit (MICU) and the cardiac intensive care unit (CICU) at Johns Hopkins Bayview Medical Center (JHBMC). JHBMC is one of three academic hospitals of the Johns Hopkins Health System, located in Baltimore City and has a potential capacity of 500 beds. The reason for choosing MICU and CICU is that both were converted to specialized COVID-19 intensive care units (ICU) to provide care for critically-ill patients confirmed to have COVID-19 infection and persons under investigation (PUI). We reviewed all adult patients (18 years or older) admitted to the intensive care units. The study was approved by Institutional Review Board at Johns Hopkins School of Medicine and all actions undertaken by the authors were in accordance with the Declaration of Helsinki.

JHBMC serves diverse populations in community statistical areas of Baltimore City that are within the hospital's proximity (ZIP Codes: 21202, 21205, 21206, 21213, 21218, 21219, 21222, 21224, and 21231). Percentage of African Americans in these regions ranges from 12.4–27.5%, while percentage of White ranges from 55.2–80.1%. Hispanic/Latinx persons range from 17.1–31.9%. Median household income ranges from $32,102 to $71,660, while the family poverty rate ranges from 15.2–43.6%.

**Time Period**

An 18-month review of data for this investigation provides an entire fiscal year of ICU admissions, allowing secular trends to be identified in how specific populations utilized critical care resources over a specific time. In addition, by capturing the first three months of 2020, we could assure that trends
observed between March to May 2020 were a) not specific to the current year and b) were not typical seasonal trends (as our data captures March to May 2019).

The 18-month data were then dichotomized into pre-COVID-19 admissions (December 1, 2018 to March 13, 2020) and COVID-19 ICU admissions (March 14, 2020 to May 31, 2020). March 14, 2020 was chosen because it was the first reported case of COVID-19 in Baltimore City\textsuperscript{13} and this timeframe correlated with an increase in COVID-19 admissions in our hospital.

**Variables of Interest**

We collected individual sociodemographic data including age, sex, race, ethnicity, and preferred language spoken (identified as “English not preferred”) of all patients admitted to the MICU and CICU during the aforementioned timeframe. We defined elderly as age 65 years and older. We also documented length of stay in the ICU as well as ICU-mortality.

**Statistical Analysis**

All continuous variables are presented as mean ± standard deviation or median (interquartile range). Categorical variables were summarized as counts and percentages. Variables were compared using Fisher’s exact tests and Wilcoxon tests when appropriate. For comparisons of more than two groups, an analysis of variance (ANOVA) was performed. Conditional density plots were utilized to display population admissions over the 18-month period. Statistical analyses were conducted with R software (V.0.99.903).

**Results**

Over the course of 18 months, the MICU and CICU saw a total of 1861 admissions. The mean age of the 1861 patients was 62.75 ± 15.57 years (range 19 to 100 years). The majority of these patients were male (52.23%), White (64.43%), and non-Hispanic/Latinx (95.75%). Of the 1861 patients, 419 (22.51%) of them did not survive their hospitalization. A complete list of sociodemographic and hospital variables is provided in Table 1.
Of the 1861 patients, 210 were admitted between mid-March 2020, after the first case of COVID-19 in Baltimore City, and May 2020. In comparing the pre-COVID-19 admissions to the COVID-19 admissions, there was no statistically significant difference in age (p = 0.18), ICU length of stay (p = 0.95), or death (p = 0.46). However, there were differences in the racial and ethnic distribution comparing the pre-COVID-19 admissions to the COVID-19 admissions. For COVID-19 compared to pre-COVID ICU admissions, the increase in African American admissions, as compared to White admissions, was statistically significant (p = 0.01) as was the increase in Hispanic/Latinx patients compared to non-Hispanic/Latinx patients (p < 0.01) (Table 1). Table 1 further dichotomizes sociodemographic variables by pre-COVID-19 admissions and COVID-19 admissions.

Hispanic/Latinx Patients

Among Hispanic/Latinx patients, 35.4% of the admissions over the 18-month period occurred between mid-March to May 2020 (Fig. 1). By May 2020, Hispanic/Latinx patients represented 21.7% (69 total patient admissions, with 15 patients being Hispanic/Latinx) of COVID-19 ICU admissions. By contrast, during the pre-COVID-19 period, Hispanic/Latinx patients represented 2.34–5.27% of monthly ICU admissions (Fig. 1). However, there was no difference in age between Hispanic/Latinx ICU patients admitted before (48.46 ± 13.07 years old) and after (49.67 ± 19.50 years old) (p = 0.75) COVID-19. There

### Table 1

Demographic data of the patient population over 18 months. Pre-COVID-19 admissions occurred from December 1, 2018 to March 14, 2020, while post-COVID-19 Admissions occurred from March 15, 2020 to May 31, 2020.

|                        | Total (N = 1861) | Pre-COVID-19 Admissions (N = 1651) | Post-COVID-19 Admissions (N = 210) | p-value |
|------------------------|------------------|------------------------------------|------------------------------------|---------|
| Age (years)            | 62.72 ± 15.57    | 62.91 ± 15.42                      | 61.28 ± 16.65                      | 0.18    |
| Male (%)               | 972 (52.23)      | 857 (51.91)                        | 115 (54.76)                        | 0.48    |
| Race (%)               |                  |                                    |                                    |         |
| African American       | 547 (29.39)      | 473 (28.65)                        | 74 (35.24)                         | 0.01    |
| White                  | 1199 (64.43)     | 1087 (65.84)                       | 112 (53.33)                        | –       |
| Other                  | 115 (6.18)       | 91 (5.51)                          | 24 (11.43)                         | < 0.01  |
| Hispanic/Latino (%)    | 79 (4.25)        | 51 (3.09)                          | 28 (13.33)                         | < 0.01  |
| English not preferred (%) | 79 (4.25)      | 52 (3.15)                          | 27 (12.86)                         | < 0.01  |
| ICU Length of Stay (days) | 2.00 (1.00, 5.00) | 3.00 (1.00, 5.00) | 2.00 (1.00, 5.75) | 0.95    |
| Death (%)              | 419 (22.51)      | 367 (22.23)                        | 52 (24.76)                         | 0.46    |
was no difference in Hispanic/Latino male patient admissions either, as they continued to represent the majority sex admitted to the ICU: 34 patients (66.67%) prior to COVID-19 and 21 (75.00%) during COVID-19 (p = 0.61). There was no difference in ICU length of stay pre- versus post-COVID-19 (p = 0.14) and no difference in mortality between the two time periods (4 deaths of Hispanic/Latinx patients prior to COVID-19 ICU admissions as compared to 1 death during COVID-19 ICU admissions) (p = 0.79).

During COVID-19 ICU admissions, Hispanic/Latinx patients were younger (48.46 ± 13.07 years old) as compared to non-Hispanic/Latinx patients (63.25 ± 16.29 years old) (p < 0.01) and predominantly male (p = 0.04). However, deaths occurred at a greater rate in non-Hispanic/Latinx patients (28.02%) as compared to Hispanic/Latinx patients (3.57%) (p = 0.01). Table 2 further emphasizes differences between race and ethnicity outcomes.

### Table 2
A break down between ethnicity and race during the COVID-19 pandemic in a Baltimore City community hospital.

|                      | Hispanic/Latinx (N = 28) | Non-Hispanic/Latinx African American (N = 74) | Non-Hispanic/Latinx White (N = 112) | p-value |
|----------------------|--------------------------|---------------------------------------------|------------------------------------|---------|
| Age (years)          | 48.46 ± 13.07            | 57.95 ± 16.63                               | 64.95 ± 15.96                     | < 0.01  |
| Male (%)             | 21 (75.00)               | 44 (59.5)                                   | 55 (49.11)                        | 0.03    |
| ICU Length of Stay (days) | 3.00 (1.75, 8.25)        | 4.00 (1.25, 7.75)                           | 2.00 (1.00, 4.25)                 | 0.08    |
| Death (%)            | 1 (3.57)                 | 23 (31.08)                                  | 29 (25.89)                        | < 0.01  |

### African American Patients

Among African American patients, 13.5% of the admissions over the 18-month period occurred between mid-March to May 2020 (Fig. 1). By May 2020, 41 African American patients (59.42%) accounted for the 69 total patient admissions to a COVID-19 ICU. By contrast, during the pre-COVID-19 period, monthly admissions to the MICU or CICU among African American patients ranged from 37.23–42.28% (Fig. 1), never achieving the majority of admissions by race in either intensive care unit. There was no statistically significant difference in age between African American patients admitted before (58.96 ± 15.91 years old) and after (57.95 ± 16.63 years old) (p = 0.56) COVID-19. There was a statistically significant difference in ICU length of stay pre-COVID-19 and during COVID-19 ICU among African American patients. Pre-COVID-19, the median ICU length of stay was 3.00 days (IQR 1.00, 6.00), while during COVID-19 the ICU length of stay was 4.00 days (IQR 1.25, 7.75) (p = 0.04). Further, there was a statistically significant difference in mortality in African American pre-COVID-19 ICU admissions (113 patients [23.89%]) as compared to African Americans during COVID-19 ICU admission (74 patients [31.08%]) (p = 0.04).
During COVID-19 ICU admissions, African American patients were younger (57.95 ± 16.63 years old) as compared to White patients (64.95 ± 15.96 years old) (p < 0.01). Further, African Americans had more ICU days as compared to Whites (p = 0.02). There was no difference in mortality between the two races during the COVID-19 ICU admissions over the 3-month period.

Elderly

Among elderly patients, 12.4% of the admissions over the 18-month period occurred between mid-March to May 2020. There was no statistically significant difference in age between elderly patients admitted before (75.42 ± 8.46 years old) and after (75.60 ± 8.60 years old) (p = 0.84) COVID-19. There was no difference in sex between pre-COVID-19 admissions and COVID-19 admissions in the elderly (p = 0.25). Prior to COVID-19 admissions, White elderly accounted for 573 (71.71%) of total elderly patients, while among COVID-19 admissions White elderly accounted for 61.61% (61 patients (p = 0.0495). Finally, there was a non-statistically significant increase in mortality in the elderly during COVID-19 admission (37 patients (37.37%)) as compared to pre-COVID-19 admissions (228 patients (28.53%)) (p = 0.82). When evaluating elderly patients by race, there was a statistically significant increase in mortality in African American elderly patients during COVID-19 admissions (23 patients (31.08%)) as compared to pre-COVID-19 admissions (113 patients (19.82%) (p = 0.02). There were no deaths in elderly Hispanic/Latino patients (6 patients total) during COVID-19 ICU admissions.

Discussion

During the first three months of admissions to a COVID-19 ICU at an urban, academic, community hospital, there was a rise in admissions among Hispanic/Latinx and African-American patients, while non-Hispanic/Latinx and White patient admissions declined over the recent 3-month period. Compared to non-Hispanic/Latinx patients admitted to the ICU, Hispanic/Latinx admitted to the COVID-19 ICU were younger. As expected given the age differential, Hispanic/Latinx had greater survival rates compared to non-Hispanic/Latinx. African American patients had worse mortality outcomes during the pandemic as compared to non-COVID-19 ICU admissions, especially elderly African American patients. Overall, this shift in both admissions and outcomes based on race and ethnicity was a significant change during the COVID-19 pandemic for this community hospital in comparison to the previous year's ICU admissions.

Disparities in critical care diagnoses and admissions have been well documented.\(^5\),\(^6\),\(^14\) And in the case of the COVID-19 pandemic, disparities continue to exist in the proportion of minorities that are impacted by COVID-19.\(^15\) In the analysis by Price-Haywood et al, they found a disproportionate impact on African Americans with COVID-19: 76.9% of the patients hospitalized were African American, and 70.6% of the patients who died were African American.\(^16\) The data reviewed spanned the first 6-weeks of the public health crisis of COVID-19 in Louisiana (March 1 to April 11, 2020). Such a disproportionate impact was also seen in African Americans in our hospital’s admissions. However, our data showcases that the pandemic had differential effects, increasing admissions of African American patients while simultaneously decreasing admissions of White patients. This finding is new, as evident by our review of
critical care admissions the previous years, which were consistently stable for both African Americans and Whites, as well as the same pattern for Hispanic/Latinx patients versus non-Hispanic/Latinx patients.

Optimization of regional ICU utilization has been a priority during the COVID-19 pandemic. Using time-lapsed, sociodemographic ICU admission may be part of the strategies to identify communities disproportionately impacted by COVID-19 and begin to attenuate such a disparity. This would parallel other interventions, where insight into ICU admissions may result in community efforts to mitigate these severe diseases. For instance, Victor et al demonstrated a community intervention to impact blood pressure control on non-Hispanic African American men by partnering with barbershops in Los Angeles; such an effort is warranted as this population has the highest rate of hypertension-related critical care admissions. ICU-level information reaﬁrms the need to promote testing and identify resources to facilitate isolation and quarantine for African Americans and Hispanic/Latinx who are experiencing COVID-19-related health disparities. Such strategies will require partnerships with neighborhood leaders to leverage community-based resources and venues to effect these collaborative changes, as well as structural changes at levels of policy and advocacy.

This study has several limitations. First, we did not evaluate more granular clinical data, such as severity of symptoms on presentation and pre-existing conditions. Second, we did not investigate what COVID-19 related syndromes warranted ICU admissions (e.g. sepsis, ARDS, heart failure). While these limitations are important to address in future studies and are necessary overall to understand the complete clinical presentation of COVID-19, we believe such information was not as relevant for implementing immediate community engagement initiatives towards populations impacted disproportionately by the pandemic. Finally, this information is relevant for our community hospital based in an urban region; it is unclear if similar ﬁndings would occur in community hospitals serving rural regions. This should be investigated in order to understand urban versus rural differences on populations as related to COVID-19 incidence and ICU admissions.

In the ﬁrst months of the pandemic, there was a signiﬁcant shift in persons admitted to an urban community hospital’s ICU with regards to socio-demographics. An increase in minority populations based on race and ethnicity was evident in COVID-19 ICUs, while non-minority populations saw a decrease in ICU admissions. While much has been said regarding the disproportionate impact in minorities due to COVID-19, we have shown, using time-lapse evaluations, that this impact is signiﬁcantly different than pre-pandemic ICU admission trends. Therefore, as strategies are discussed to curb the incidence of COVID-19 in minority populations, monitoring if such a reduction results in a decrease in ICU admissions should be emphasized as a public health priority.
