FOLIATIONS ON THE PROJECTIVE PLANE WITH FINITE GROUP OF SYMMETRIES

ALAN MUNIZ AND RUDY ROSAS

Abstract. Let $\mathcal{F}$ denote a singular holomorphic foliation on $\mathbb{P}^2$ having a finite automorphism group $\text{Aut}(\mathcal{F})$. Fixed the degree of $\mathcal{F}$, we determine the maximal value that $|\text{Aut}(\mathcal{F})|$ can take and explicitly exhibit all the foliations attaining this maximal value. Furthermore, we classify the foliations with large but finite automorphism group.

1. Introduction

The presence of symmetries has been used to understand some relevant problems in holomorphic foliation theory, especially concerning integrability. For instance, it is used in the construction of Jouanolou’s foliations [11], which play an important role in his proof of the density of foliations on the complex projective plane $\mathbb{P}^2$ without invariant algebraic curves; in [17] this relation between automorphism groups and integrability was explored and put into more concrete terms.

A new perspective for the study of these automorphism groups arises after the birational classification of foliated surfaces, given independently by McQuillan and Mendes – see [4]. This is a foliated counterpart of the classical Enriqués-Kodaira work on surfaces. From the works of Hurwitz and Klein for curves and the work of Andreotti in higher dimension, the question about the finiteness of automorphism groups of foliations appears naturally. In 2002, Pereira and Sánchez [16] proved a foliated version of Andreotti’s theorem: foliated surfaces of general type have finite self-bimeromorphism groups. Then arises the question: how large these finite groups can be? To propose a more precise question we restrict our study to the case of singular holomorphic foliations on $\mathbb{P}^2$: is there a function $f: \mathbb{N} \to \mathbb{N}$ such that, for any singular holomorphic foliation $\mathcal{F}$ of degree $d$ on $\mathbb{P}^2$ with $|\text{Aut}(\mathcal{F})| < +\infty$ we have

$$|\text{Aut}(\mathcal{F})| \leq f(d)?$$

if the response is yes, what is the minimal function $f$? In [7], Corrêa and the first author of this paper show that the function $f(d) = 3(d^2 + d + 1)$ bounds the order of $\text{Aut}(\mathcal{F})$ for a generic class of foliations $\mathcal{F}$ of degree $d$. The maximal value $3(d^2 + d + 1)$ in this class is attained by the Jouanolou Foliation [11]. In the present work, we show that the bound $3(d^2 + d + 1)$ does not work for all foliations but we prove that the function $f$ indeed exists. First of all, recall that foliations of degree 0 or 1 have infinitely many automorphism, so we only need to look by a function $f$ defined on $\{2, 3, \ldots\}$.

Theorem 1.1. Let $f: \{2, 3, \ldots\} \to \mathbb{N}$ be defined by $f(2) = 24$, $f(3) = 39$, $f(4) = 216$ and $f(d) = 6(d - 1)^2$ for $d \geq 5$. Then, if $\mathcal{F}$ is a degree $d$ foliation on $\mathbb{P}^2$ such that $|\text{Aut}(\mathcal{F})| < +\infty$, we have

$$|\text{Aut}(\mathcal{F})| \leq f(d).$$
Moreover, this bound is sharp: there exist foliations attaining this bound for any degree \( d \geq 2 \).

Furthermore, our main goal is to give a complete classification of the foliations with large but finite automorphism group. In particular, we present all the foliations attaining the bound \( f(d) \) in Theorem 1.1.

**Theorem 1.2.** Let \( \mathcal{F} \) be a foliation of degree \( d \geq 2 \) on \( \mathbb{P}^2 \) such that

\[
3(d^2 + d + 1) \leq |\text{Aut}(\mathcal{F})| \leq f(d).
\]

Then \( \mathcal{F} \) is projectively equivalent to one of the foliations in the following table – \( \mathcal{T} \) and \( \mathcal{T} \) are the binary tetrahedral and icosahedral groups, respectively.

| Fol. | degree | \( |\text{Aut}(\mathcal{F})| \) | \( \text{Aut}(\mathcal{F}) \) | description |
|------|--------|-----------------|-----------------|-------------|
| \( \mathcal{J}_d \) | \( d \) | \( 3(d^2 + d + 1) \) | \( \mathbb{Z}/(d^2 + d + 1)\mathbb{Z} \times \mathbb{Z}/3\mathbb{Z} \) | Jouanolou foliation |
| \( \mathcal{G}_d \) | \( d \geq 5 \) | \( 6(d - 1)^2 \) | \( \mathbb{Z}/(d - 1)\mathbb{Z} \times S_3 \) | nonisotrivial hyperbolic fibration |
| \( \mathcal{F}_d \) | \( d \geq 5 \) | | \( \mathbb{Z}/d\mathbb{Z} \times S_3 \) | isotrivial hyperbolic fibration |
| \( \mathcal{P}_5 \) | 5 | 96 | \( \mathbb{Z}/2\mathbb{Z} \times \mathcal{T} \times \mathbb{Z}/2\mathbb{Z} \) | general type Bernoulli foliation |
| \( \mathcal{P}_{11} \) | 11 | 600 | \( \mathbb{Z}/5\mathbb{Z} \times \mathcal{T} \) | rational fibration |
| \( \mathcal{S} \) | 2 | 24 | \( \mathbb{Z}/2\mathbb{Z} \times S_3 \) | nonisotrivial elliptic fibration |
| \( \mathcal{H}_4 \) | 4 | 216 | \( \text{Hessian group} \) | |
| \( \mathcal{H}_7 \) | 7 | | | nonisotrivial hyperbolic fibration |

In particular, the extremal equality \( |\text{Aut}(\mathcal{F})| = f(d) \) is attained by the fibration \( \mathcal{S} \) if \( d = 2 \), the Jouanolou foliation \( \mathcal{J}_3 \) if \( d = 3 \), the foliation \( \mathcal{H}_4 \) if \( d = 4 \), the foliations \( \mathcal{G}_5 \), \( \mathcal{F}_5 \) and \( \mathcal{P}_5 \) if \( d = 5 \), and the foliations \( \mathcal{G}_d \) and \( \mathcal{F}_d \) if \( d \geq 6 \).

Besides the well known Jouanolou foliations \( \mathcal{J}_d \), the foliations \( \mathcal{F}_d \), \( \mathcal{H}_4 \) and \( \mathcal{H}_{11} \) are already described in the literature: they appear in [13] as examples of reduced convex foliations; these are, respectively, the Fermat foliations \( \mathcal{F}_d \), the Hesse pencil of cubics \( \mathcal{H}_4 \) and the foliation \( \mathcal{H}_7 \) associated to the extended Hesse configuration of lines. The other foliations are described in Section 3 but it is worth mentioning here that, with the only exception of \( \mathcal{J}_d \), all foliation in Table 1.2 have some kind of first integral: the Bernoulli foliations have Liouvillian first integrals, and all the others have rational first integrals. Moreover, from Table 1.2 we can derive the following fact: since the canonical bundle of \( \mathcal{F} \) is \( K_\mathcal{F} = \mathcal{O}_{\mathbb{P}^2}(d - 1) \), we have a linear bound for \( |\text{Aut}(\mathcal{F})| \) in terms of the Chern number \( K_\mathcal{F}^2 \); this kind of bounds are obtained in [8] for foliations with ample canonical bundle on projective surfaces.

This paper is organized as follows. In Section 2 we recall some basic definitions and results about foliations. In Section 3 we describe the foliations already mentioned in our main theorems. In Section 4 we reduce the proof of our main theorems to a variety of specific results according to the classification of finite groups of \( \text{PGL}(3, \mathbb{C}) \). The remaining sections are devoted to prove the results presented in Section 4. It is worth mentioning that in Section 8 we develop a Molien-type formula – Theorem 8.1 – that is fundamental to analyze the transitive primitive groups. This formula leads to some simple but very long calculations that we have managed to do with Maple™.

2. Preliminaries

Foliations on \(\mathbb{P}^2\). In this paper we consider singular holomorphic foliations by curves – foliations for short – with isolated singularities on \(\mathbb{P}^2\). Such a foliation can be defined in an affine chart \(\mathbb{C}^2\) with coordinates \((x,y)\) by a polynomial vector field \(P\partial_x + Q\partial_y\) with isolated singularities or even by a polynomial 1-form, for example the form \(Qdx - Pdy\). Conversely, a polynomial vector field or 1-form with isolated singularities on \(\mathbb{C}^2\) defines a unique holomorphic foliation with isolated singularities on \(\mathbb{P}^2\). The degree of a foliation \(\mathcal{F}\) – denoted by \(\deg(\mathcal{F})\) – is geometrically defined as the number of tangencies of \(\mathcal{F}\) with a generic line in \(\mathbb{P}^2\). This degree reflects on the polynomial 1-form defining \(\mathcal{F}\) in the following way. Let \(\omega\) be a polynomial 1-form with isolated singularities defining \(\mathcal{F}\) and write it in the form

\[
\omega = \sum_{j=0}^{k} (A_j dx + B_j dy),
\]

where \(A_j\) and \(B_j\) are homogeneous polynomials of degree \(j\), and \(A_k dx + B_k dy \neq 0\). Then we have the following possibilities:

1. The polynomial \(A_k x + B_k y\) is not zero; in this case the line at infinity of \(\mathbb{P}^2\) is invariant by \(\mathcal{F}\) and we have \(\deg(\mathcal{F}) = k\).
2. The polynomial \(A_k x + B_k y\) is zero; in this case the line at infinity of \(\mathbb{P}^2\) is generically transverse to \(\mathcal{F}\) and we have \(\deg(\mathcal{F}) = k - 1\).

In a more global point of view, a foliation \(\mathcal{F}\) of degree \(d\) can also be defined by homogeneous vector field in three variables: there exists a polynomial vector field \(v = A\partial_X + B\partial_Y + C\partial_Z\) of degree \(d\) in \(\mathbb{C}^3\) which induce – via the natural projection \(\mathbb{C}^3 \setminus \{0\} \to \mathbb{P}^2\) – a singular holomorphic distribution of lines on \(\mathbb{P}^2\) coinciding with the tangent distribution of \(\mathcal{F}\).

Another homogeneous vector field \(w\) of degree \(d\) induce the same foliation \(\mathcal{F}\) if and only if there exist \(\alpha \in \mathbb{C}^*\) and a polynomial \(P\) of degree \(d - 1\) such that

\[
w = \alpha v + P(X\partial_X + Y\partial_Y + Z\partial_Z).
\]

From this it is easy to see that we can find a homogeneous vector field \(w\) defining \(\mathcal{F}\) and such that \(\text{div}(w) = 0\), where \(\text{div}(w)\) is the divergence of \(w\) with respect to \(dX \wedge dY \wedge dZ\). This choice of vector field is called the Darboux normal form and it is unique – up to scalar multiplication, see [11, p.6] and [9, p.63]

Automorphisms. A biholomorphism \(\varphi : \mathbb{P}^2 \to \mathbb{P}^2\) is an automorphism of \(\mathcal{F}\) if \(\varphi\) maps each leaf of \(\mathcal{F}\) onto a leaf of \(\mathcal{F}\). The set of automorphisms of \(\mathcal{F}\) is a group, which is denoted by \(\text{Aut}(\mathcal{F})\). If \(v\) is a homogeneous vector field in \(\mathbb{C}^3\) defining \(\mathcal{F}\), then the image of an element \(\varphi \in \text{GL}(3, \mathbb{C})\) in \(\text{PGL}(3, \mathbb{C})\) is an automorphism of \(\mathcal{F}\) if and only if the pushforward \(\varphi_* v = \varphi \cdot (v \circ \varphi^{-1})\) is also a vector field defining \(\mathcal{F}\). Hence, given a finite subgroup \(G\) of \(\text{GL}(3, \mathbb{C})\), its image in \(\text{PGL}(3, \mathbb{C})\) preserves the foliation defined by \(v\) with \(\text{div}(v) = 0\) if there exists a character \(\chi : G \to \mathbb{C}^*\) such that, for all \(\varphi \in G\),

\[
\varphi_* v = \chi(\varphi) v.
\]

If this is the case, we also say that the vector field \(v\) is \(G\)-semi-invariant.

3. Examples

In this section we describe those foliations already mentioned in Theorem 1.2. Hereafter we will work with homogeneous coordinates \((X : Y : Z)\) on \(\mathbb{P}^2\) and \((x,y)\) will denote the natural coordinates in \(\{Z \neq 0\}\).

3.1. The Jouanolou Foliation \(\mathcal{J}_d\). The Jouanolou foliation of degree \(d\), denoted by \(\mathcal{J}_d\), is defined by the vector field

\[
Y^d \partial_X + Z^d \partial_Y + X^d \partial_Z
\]

or, in affine coordinates, by the 1-form

\[
(x^d y - 1) dx + (y^d - x^{d+1}) dy.
\]
The automorphism group of \( J_d \) has order \( 3(d^2 + d + 1) \) and it is generated by the maps \([X : Y : Z] \mapsto [Y : Z : X]\) and \([X : Y : Z] \mapsto [t^{d+1} X : tY : Z]\), where \( t^{d^2 + d + 1} = 1 \) with \( t \) primitive.

3.2. The Fermat Foliation \( F_d \). The Fermat foliation \( F_d \) of degree \( d \) – already described in [13] – is generated by the vector field

\[
X^d \partial X + Y^d \partial Y + Z^d \partial Z.
\]

In affine coordinates we can define \( F_d \) by the 1-form

\[
(y - y^d) dx - (x - x^d) dy
\]

or even by the rational first integral

\[
\frac{x^{1-d} - 1}{y^{1-d} - 1}.
\]

This foliation has an automorphism group of order \( 6(d - 1)^2 \), generated by the transformations

\[
[X : Y : Z] \mapsto [Y : Z : X],
[X : Y : Z] \mapsto [X : Z : Y],
[X : Y : Z] \mapsto [\lambda X : Y : Z] \quad \text{and}
[X : Y : Z] \mapsto [X : \lambda Y : Z],
\]

where \( \lambda \) is a primitive \((d - 1)\)th root of unity.

3.3. The Foliation \( G_d \). In affine coordinates, this degree \( d \) foliation is defined by the rational first integral

\[
\frac{(x^{d-1} + y^{d-1} + 1)^3}{x^{d-1} y^{d-1}}
\]

or by the 1-form

\[
(y + y^d - 2x^{d-1} y) dx + (x + x^d - 2xy^{d-1}) dy.
\]

This foliation has the same group of automorphisms as the Fermat foliation \( F_d \). For \( d \geq 5 \), the foliation \( G_d \) is birational to a nonisotrivial hyperbolic fibration and is therefore of general type.

3.4. The Hessian Foliations \( \mathcal{H}_4 \) and \( \mathcal{H}_7 \). The foliation \( \mathcal{H}_4 \) is the degree 4 foliation given by the well known Hesse pencil of cubics. This foliation has the rational first integral

\[
[X : Y : Z] \mapsto [X^3 + Y^3 + Z^3 : XYZ].
\]

On the other hand, the foliation \( \mathcal{H}_7 \) – see [13] – is the degree 7 foliation given in affine coordinates by the vector field

\[
(x^3 - 1)(x^3 + 7y^3 + 1)x \partial_x + (y^3 - 1)(y^3 + 7x^3 + 1)y \partial_y.
\]

This foliation leaves invariant the extended Hessian arrangement of 21 lines on the plane and it is tangent to a pencil of curves of degree 72. The automorphism group of both foliations \( \mathcal{H}_4 \) and \( \mathcal{H}_7 \) is the classical Hessian Group – see [13] – of order 216, generated by the maps

\[
[X : Y : Z] \mapsto [Y : Z : X],
[X : Y : Z] \mapsto [X : Y : \lambda Z],
[X : Y : Z] \mapsto [X : \lambda Y : \lambda^2 Z] \quad \text{and}
[X : Y : Z] \mapsto [X + Y + Z : X + \lambda Y + \lambda^2 Z : X + \lambda^2 Y + \lambda Z],
\]

where \( \lambda \) is a primitive cubic root of unity. See [13] for more details about the foliations \( \mathcal{H}_4 \) and \( \mathcal{H}_7 \).
3.5. The Rational Fibration $S$. The foliation $S$ is the foliation of degree 2 defined by the vector field

$$YZ\partial_X + ZX\partial_Y + XY\partial_Z.$$ 

In affine coordinates, $S$ is defined by the 1-form

$$(-x + xy^2)\,dx + (y - x^2y)\,dy$$

or by the rational first integral

$$\frac{1 - x^2}{1 - y^2}.$$ 

This foliation has the same group – of order 24 – as the Fermat foliation $F_3$.

3.6. The Bernoulli Foliations $\mathcal{P}_5$ and $\mathcal{P}_{11}$. The degree 5 foliation $\mathcal{P}_5$ and the degree 11 foliation $\mathcal{P}_{11}$ are defined by the 1-forms

$$xdy - ydx + d(x^5y - xy^5)$$

and

$$xdy - ydx + d(x^{11}y + 11x^6y^6 - xy^{11}),$$

respectively. In the affine coordinates $(x, y)$ above, $\text{Aut}(\mathcal{P}_5)$ is a subgroup of order 96 of $\text{GL}(2, \mathbb{C})$. The center of this group is $\{\lambda I : \lambda^4 = 1\}$ and its image in $\text{PGL}(2, \mathbb{C})$ is the octahedral group presented in such way its smallest orbit is given by the 6 lines

$$x^5y - xy^5 = 0.$$ 

On the other hand, the group $\text{Aut}(\mathcal{P}_{11})$ is the subgroup of order 600 of $\text{GL}(2, \mathbb{C})$ having $\{\lambda I : \lambda^{10} = 1\}$ as its center and whose image in $\text{PGL}(2, \mathbb{C})$ is the icosahedral group presented in such way its smallest orbit is given by the 12 lines

$$x^{11}y + 11x^6y^6 - xy^{11} = 0.$$ 

The foliations $\mathcal{P}_5$ and $\mathcal{P}_{11}$ have no rational first integrals but they are particularly special: since both foliations are presented in the form

$$xdy - ydx + dP = 0,$$  \hspace{1cm} (3.1)

where $P$ is a square free homogeneous polynomial of degree $\geq 4$, they have nondegenerate singularities and both foliations are of general type. Moreover, if we do the change of coordinates $(x, y) = (\frac{t}{z}, \frac{1}{z})$ in Equation (3.1) we obtain the Bernoulli equation

$$nP(t, 1)\frac{dz}{dt} = P_5(t, 1)z - z^{n-1},$$

so $\mathcal{P}_5$ and $\mathcal{P}_{11}$ have Liouvillian first integrals – see [6].
4.1. Abelian groups of diagonal matrices. A group in this class is such that, in suitable homogeneous coordinates, all its elements are of the form

\[ [X : Y : Z] \mapsto [aX : bY : Z], \]

where \( a, b \in \mathbb{C}^* \). About the foliations having such a group of automorphisms, we have the following result which is a corollary of Proposition 5.2.

**Proposition 4.1.** Suppose that \( \text{Aut}(\mathcal{F}) \) is a finite abelian group of diagonal matrices. Then

\[ |\text{Aut}(\mathcal{F})| \leq d^2 + d + 1 \]

4.2. Finite non abelian subgroups of \( \text{GL}(2, \mathbb{C}) \). In suitable homogeneous coordinates, a group in this class is composed by transformations of the form

\[ [X : Y : Z] \mapsto [aX + bY : cX + dY : Z], \]

where \( \begin{bmatrix} a & b \\ c & d \end{bmatrix} \) belongs to a finite non abelian subgroup \( G \) of \( \text{GL}(2, \mathbb{C}) \). Recall that the image of \( G \) in \( \text{PGL}(2, \mathbb{C}) \), being finite, is one of the following groups:

1. A dihedral group.
2. A polyhedral group, so we have three possibilities:
   (a) The Tetrahedral Group \( T \), isomorphic to the alternating group \( A_4 \);
   (b) The Octahedral Group \( O \), isomorphic to the symmetric group \( S_4 \);
   (c) The Icosahedral Group \( I \), isomorphic to the alternating group \( A_5 \).

In relation with the dihedral case, in Section 5 we prove the following result.

**Proposition 4.2.** Suppose that the image of \( \text{Aut}(\mathcal{F}) \) in \( \text{PGL}(2, \mathbb{C}) \) is a dihedral group. Then

\[ |\text{Aut}(\mathcal{F})| \leq 2(d^2 + d + 1) \]

For the polyhedral case we have the following result, proved in Section 7.

**Proposition 4.3.** Suppose that the image of \( \text{Aut}(\mathcal{F}) \) in \( \text{PGL}(2, \mathbb{C}) \) is a polyhedral group. Then

\[ |\text{Aut}(\mathcal{F})| \geq 3(d^2 + d + 1) \]

if and only if \( \mathcal{F} \) is equivalent to one of the Bernoulli foliations \( \mathcal{P}_5 \) or \( \mathcal{P}_{11} \).

4.3. Transitive imprimitive groups. In this case we have two types of groups. The first type is composed by those groups such that, in suitable homogeneous coordinates, they are generated by the transformation

\[ [X : Y : Z] \mapsto [Y : Z : X] \]

and a group of transformations of the form

\[ [X : Y : Z] \mapsto [aX : bY : Z]. \]

**Proposition 4.4.** Suppose that \( \text{Aut}(\mathcal{F}) \) is a group of the type above. Then

\[ |\text{Aut}(\mathcal{F})| \leq 3(d^2 + d + 1) \]

and the equality holds if and only if \( \mathcal{F} \) is isomorphic to the Jouanolou foliation \( \mathcal{J}_4 \).

The second type of transitive imprimitive groups is composed by those groups such that, in suitable homogeneous coordinates, they are generated by

\[ [X : Y : Z] \mapsto [Y : Z : X], \]

a transformation of the form

\[ [X : Y : Z] \mapsto [\mu Y : \nu X : Z], \]

where \( \mu, \nu \in \mathbb{C}^* \), and a group of transformations of the form

\[ [X : Y : Z] \mapsto [aX : bY : Z]. \]

**Proposition 4.5.** Suppose that \( \text{Aut}(\mathcal{F}) \) is a group of the type above.
(1) Assume that the line at infinity $Z = 0$ is invariant by $\mathcal{F}$. Then
\[ |\text{Aut}(\mathcal{F})| \leq 6(d - 1)^2 \]
and the equality holds if and only if $\mathcal{F}$ is isomorphic to $\mathcal{F}_d$ or $\mathcal{G}_d$. Moreover, if $\mathcal{F}$ is different from $\mathcal{F}_d$ and $\mathcal{G}_d$ we have
\[ |\text{Aut}(\mathcal{F})| < 3(d^2 + d + 1). \]

(2) If the line at infinity is generically transverse to $\mathcal{F}$, then
\[ |\text{Aut}(\mathcal{F})| \geq 3(d^2 + d + 1) \]
if and only if $\mathcal{F}$ is equivalent to the foliation $\mathcal{S}$.

Proposition 4.4 and Proposition 4.5 are proved in Section 6.

4.4. Transitive primitive groups having a non-trivial normal subgroup. Up to isomorphism, we have three groups in this class:

(1) The Hessian Group $G$, already presented in Subsection 3.3.

(2) The normal subgroup $E \triangleleft G$ generated by the transformations
\[ T[X : Y : Z] = [Y : Z : X], \]
\[ S[X : Y : Z] = [X : \lambda Y : \lambda^2 Z], \]
\[ V[X : Y : Z] = [X + Y + Z : X + \lambda Y + \lambda^2 Z : X + \lambda^2 Y + \lambda Z]. \]

(3) The normal subgroup $F \triangleleft G$ generated by the group $E$ and the map $UVU^{-1}$, where
\[ U[X : Y : Z] = [X : Y : \lambda Z]. \]

Proposition 4.6. Suppose that $\text{Aut}(\mathcal{F})$ is a transitive primitive group having a non-trivial normal subgroup. Then, we have
\[ |\text{Aut}(\mathcal{F})| \geq 3(d^2 + d + 1) \]
if and only if $\mathcal{F}$ is equivalent to one of the Hessian foliations $\mathcal{H}_4$ or $\mathcal{H}_7$.

This result is proved in Section 6.

4.5. Transitive primitive simple groups. Up to isomorphism, we have three groups in this class: The icosahedral group which is isomorphic to $A_5$, the image of the Valentiner Group in $\text{PGL}(3, \mathbb{C})$ which is isomorphic to $A_5$, and the Klenian group isomorphic to $\text{PSL}(2, \mathbb{F}_7)$. In this case we have the following result, proved in Section 6.

Proposition 4.7. Suppose that $\text{Aut}(\mathcal{F})$ is a transitive primitive simple group. Then
\[ |\text{Aut}(\mathcal{F})| < 3(d^2 + d + 1). \]

5. Foliations with finite group of diagonal automorphisms

In this section we study foliations on $\mathbb{P}^2$ having finitely many automorphisms of the form
\[ [X : Y : Z] \mapsto [aX : bY : Z] \]
which correspond to $(x, y) \mapsto (ax, by)$ in the natural affine coordinates on $\{Z \neq 0\}$.

Consider a polynomial 1-form $\omega = Adx + Bdy$ in $\mathbb{C}^2$. We assume that $A$ and $B$ have no common factor in $\mathbb{C}[x, y]$, so that $\omega$ has isolated singularities. We can write
\[ \omega = \sum_{i,j \geq 0} \alpha_{ij} x^i y^j dx + \sum_{i,j \geq 0} \beta_{ij} x^i y^j dy, \]
where $\alpha_{ij}, \beta_{ij} \in \mathbb{C}$. To each monomial form $\alpha_{ij} x^i y^j dx$, $\alpha_{ij} \neq 0$ or $\beta_{ij} x^i y^j dy$, $\beta_{ij} \neq 0$ appearing in $\omega$, associate respectively the monomial $x^{i+1} y^j$ or $x^i y^{j+1}$ and consider the set
\[ \mathcal{M} = \{x^{i+1} y^j : \alpha_{ij} \neq 0\} \cup \{x^i y^{j+1} : \beta_{ij} \neq 0\}. \]
Set
\[ \mathcal{M}' = \{m - m' : m, m' \in \mathcal{M}\}. \]
Given \( f \in \mathcal{M} \) nonzero, write \( f = x^k y^l \tilde{f} \) with \( k, l \geq 0 \) and \( \langle \tilde{f}, xy \rangle = 1 \), and define the set
\[
\mathcal{S} = \{ \tilde{f}; f \in \mathcal{M} \}.
\]

Let \( \mathcal{F} \) be the singular holomorphic foliation defined by \( \omega \) on \( \mathbb{C}^2 \) and let \( G \) be the group of transformations of the form \( (x, y) \mapsto (ax, by) \), \( a, b \in \mathbb{C}^* \) that leave \( \mathcal{F} \) invariant. Precisely, \( G \) is composed by the maps \( g \) of the form \( (x, y) \mapsto (ax, by) \) such that \( g^* \omega \wedge \omega = 0 \) which is equivalent to \( g^* \omega = \theta \omega \) for some \( \theta \in \mathbb{C}^* \).

**Lemma 5.1.** Let \( \omega, S \) and \( G \) be as above. Let \( V(S) \subset \mathbb{C}^2 \) be the algebraic set defined by \( S \). Then there exists a bijection between \( G \) and \( V(S) \cap (\mathbb{C}^*)^2 \). Precisely, the map \( (x, y) \mapsto (ax, by) \), \( a, b \in \mathbb{C}^* \) belongs to \( G \) if and only if \( (a, b) \) belongs to \( V(S) \). In particular \( G \) is finite if and only if \( \mathbb{C}^2 \).

**Proof.** Let \( g(x, y) = (ax, by) \) with \( a, b \in \mathbb{C}^* \). If \( g \in G \) there exists \( \theta \in \mathbb{C}^* \) such that \( g^* \omega = \theta \omega \), that is:
\[
\sum_{\alpha, \beta, \rho} a^{i+1}b^l \alpha \beta \rho x^{i}y^{j} dx + \sum_{\alpha, \beta, \rho} a^{i+1}b^l \alpha \beta \rho x^{i}y^{j} dy = \sum_{\alpha, \beta, \rho} \theta \alpha \beta \rho x^{i}y^{j} dx + \sum_{\alpha, \beta, \rho} \theta \alpha \beta \rho x^{i}y^{j} dy,
\]
and equality holds if and only if, up to the symmetry \( (x, y) \mapsto (y, x) \), the form \( \omega \) is equal to
\[
\omega_{\alpha, \beta, \rho} = (\alpha + \beta x^d) dx + (\beta y^d - \beta x^{d+1}) dy
\]
for some \( \alpha, \beta, \rho \in \mathbb{C}^* \).

We now state and prove the main result of this section.

**Proposition 5.2.** Let \( \omega, \mathcal{F} \) and \( G \) be as in Lemma 5.1 and suppose moreover that \( G \) is finite. Let \( d \) be the degree of the extension of \( \mathcal{F} \) to \( \mathbb{P}^2 \). Then
\[
|\mathcal{G}| \leq d^2 + d + 1
\]
and equality holds if and only if, up to the symmetry \( (x, y) \mapsto (y, x) \), the form \( \omega \) is equal to
\[
\omega_{\alpha, \beta, \rho} = (\alpha + \beta x^d) dx + (\beta y^d - \beta x^{d+1}) dy
\]
for some \( \alpha, \beta, \rho \in \mathbb{C}^* \).

We need the following lemma, whose proof is given at the end of this section.

**Lemma 5.3.** Let \( S \) be a finite set of polynomials in \( \mathbb{C}[x, y] \) and set \( N = \max \deg f \) for all \( f \in S \).

**Suppose that \( V(S) \) is finite.** Then \( |V(S)| \leq N \deg f \) for all \( f \in S \).

**Proof of Proposition 5.2.** Suppose first that the line at infinity is invariant by \( \mathcal{F} \). Let us prove that \( |\mathcal{G}| \leq d^2 + d \). Since the line at infinity is invariant by \( \mathcal{F} \), we have \( \deg A, \deg B \leq d \), hence the monomials in \( \mathcal{M} \) have at most degree \( d + 1 \) and therefore \( \deg \tilde{f} \leq d + 1 \) for all \( \tilde{f} \in S \), here \( S \) is as defined in the beginning of this section. Thus, in view of Lemma 5.3, in order to prove that \( |\mathcal{G}| \leq d^2 + d \) it suffices to find some \( \tilde{f} \in S \) with \( \deg \tilde{f} \leq d \). Observe that there exist three pairwise distinct monomials in \( \mathcal{M} \); otherwise \( S \) would contain only one element modulo sign and \( V(S) \) is infinite. We can choose two between these three monomials, say \( m_1 \) and \( m_2 \), such that both are divisible by \( x \) or both are divisible by \( y \). Then we have \( m_1 - m_2 = x^k y^l \tilde{f} \) with \( \tilde{f} \in S \), \( k + l \geq 1 \), so that \( \deg \tilde{f} \leq d \).

Suppose now that the line at infinity is generically transverse to \( \mathcal{F} \). Then the polynomial form \( \omega \) defining \( \mathcal{F} \) can be expressed as
\[
\omega = A dx + B dy + yQ dx - xQ dy,
\]
where \( \bar{A} = 0 \) or \( \deg \bar{A} \leq d \), \( \bar{B} = 0 \) or \( \deg \bar{B} \leq d \), and \( Q \equiv 0 \) is homogeneous of degree \( d \). Take two monomials \( m, m' \in \mathcal{M} \) with \( f = m - m' = 0 \). If these two monomials are associated to monomial forms appearing in \( A dx + B dy \), we have \( \deg m, \deg m' \leq d + 1 \) and therefore \( \deg \tilde{f} \leq \deg f \leq d + 1 \). If \( m \) or \( m' \), say \( m \), is associated to a monomial form appearing in \( yQ dx - xQ dy \), then \( m \in \{ xy \} \). Then, since \( m' \) is divisible by \( x \) or \( y \), we have \( f = m - m' = x^k y^l \tilde{f} \) with \( k + l \geq 1 \) and we obtain again \( \deg f \leq d + 1 \). Therefore \( \deg f \leq d + 1 \) for all \( \tilde{f} \in S \). If there
exists \( f \in S \) with \( \deg f < d + 1 \), again by Lemma 5.3 we obtain \( |G| \leq d^2 + d \). Thus we can assume that \( \deg f = d + 1 \) for all \( f \in S \). Suppose that there exist two different monomials \( m \) and \( m' \) in \( M \) of degree \( d + 2 \). Then these monomials are associated to monomial forms in \( yQdx - xQdy \), so both monomials \( m \) and \( m' \) are divisible by \( xy \) and therefore \( m - m' \) generates an element in \( S \) of degree \( \leq d \), which is a contradiction. We conclude that there exists a unique monomial in \( M \) of the form \( m = x^{p+1}y^{q+1}, p, q \geq 0, p + q = d \) and any other monomial in \( M \) has degree \( \leq d + 1 \). As above, there exist at least two other monomials \( m_1 \) and \( m_2 \) different from \( m \). Suppose that there exists another monomial \( m_3 \in M \) different from \( m, m_1 \) and \( m_2 \). Then, there is a pair of monomials in \( \{m_1, m_2, m_3\} \), say \( m_1 \) and \( m_2 \), which are both divisible by \( x \). Then, since \( \deg m_1, \deg m_2 \leq d + 1 \), we have that \( m_1 - m_2 \) generates an element in \( S \) of degree smaller than \( d + 1 \), which is a contradiction. Then \( M \) contains exactly two monomials other than \( m \), say \( m_1 \) and \( m_2 \), which have degree at most \( d + 1 \). If \( m_1 \) and \( m_2 \) have some common factor, again we have that \( m_1 - m_2 \) generates an element in \( S \) of degree smaller than \( d + 1 \); so we can assume that \( m_1 = x^{k_1}, m_2 = y^{k_2} \) for some \( k_1, k_2 \in \mathbb{N} \). Then \( f = x^{k_1} - y^{k_2} \) is contained in \( S \), so that \( \max(k_1, k_2) = \deg f = d + 1 \). Suppose that \( k_2 = d + 1 \); the other case is equal to the first one up to the symmetry \( (x, y) \mapsto (y, x) \). Since \( m - m_2 = x^{k_1}y^{k_1} - y^{d+1} \) generates an element in \( S \) of degree \( d + 1 \), we deduce that \( q = 0 \), so that \( m = x^{d+1}y \). Now, since \( m - m_1 = x^{d+1} - x^{d+1} \) generates an element of degree \( d + 1 \) in \( S \), we obtain \( k_1 = 1 \) and therefore \( m_1 = x \). Then \( M = \{x^{d+1}y, x, y^{d+1}\} \) and therefore

\[
S = \{x(x^d - 1), x(x^{d+1} - 1), x(x - y^{d+1})\}.
\]

It follows that

\[
V(S) = V(x^d y - 1, x^{d+1} - y^d),
\]

which gives

\[
|G| = |V(S)| = d^2 + d + 1.\tag{5.2}
\]

Observe that the equality above only happens if the line at infinity is generically transverse to \( F \) and \( M = \{x^{d+1}y, x, y^{d+1}\} \). From the construction of \( M \) it follows that \( \tilde{A} = \alpha, \tilde{B} = \beta y^d \) and \( Q = \rho x^d \), i.e.

\[
\omega_{\alpha, \beta, \rho} = (\alpha + \rho x^d)dx + (\beta y^d - \rho x^{d+1})dy,
\]

where \( \alpha, \beta, \rho \in \mathbb{C}^* \). Finally, it is easy to see that the foliation defined by \( \omega_{\alpha, \beta, \rho} \) has degree \( d \) and \( d^2 + d + 1 \) diagonal automorphisms.

**Proof of Proposition 4.2.** Recall that a dihedral subgroup of \( \text{PGL}(2, \mathbb{C}) \) is generated by a cyclic subgroup of index two which fixes two different points in \( \mathbb{P}^1 \) together with an automorphism of \( \mathbb{P}^1 \) permuting these two points. Then there are homogeneous coordinates such that \( \text{Aut}(\mathcal{F}) \) is generated by a group of diagonal transformations together with a map of the form

\[
R: [x : y : z] \mapsto [\mu y : \nu x : z],
\]

where \( \mu, \nu \in \mathbb{C}^* \). By Proposition 5.2, the subgroup \( G \) of diagonal transformations in \( \text{Aut}(\mathcal{F}) \) satisfies \( |G| \leq d^2 + d + 1 \). Thus, since \( |\text{Aut}(\mathcal{F}) : G| = 2 \), we obtain

\[
|\text{Aut}(\mathcal{F})| \leq 2(d^2 + d + 1).
\]

**Lemma 5.4.** Let \( \mathcal{F}, M \) and \( G \) be as defined at the beginning of this section. Suppose that

\begin{enumerate}
\item \( \mathcal{F} \) has degree \( d \geq 2 \);
\item the line at infinity is invariant by \( \mathcal{F} \); and
\item \( M \) contains \( M = \{xy, x^dy, xy^d\} \).
\end{enumerate}

Then \( |G| = (d - 1)^2 \) if \( M = M \) and \( |G| < (d^2 + d + 1)/2 \) otherwise.

**Proof.** Suppose \( M = M \). Then

\[
S = \{x(x^d - 1), x(x^{d+1} - 1), x(x - y^{d+1})\},
\]
so that
\[ |G| = \#V(x^{d-1} - 1, y^{d-1} - 1) = (d - 1)^2. \]
Assume that \( \mathcal{M} \) contains some monomial \( m \notin M \). Suppose first that \( m = x^k \) for some positive integer \( k \). If \( k = 1 \), we obtain that \( y - 1 \) belongs to \( S \) and therefore
\[ |G| \leq \#V(y - 1, x^{d-1} - 1) = d - 1 < \frac{d^2 + d + 1}{2}. \]
If \( k \in \{d, d + 1\} \), then \( x^k - x^d y = x^d(x^\xi - y) \) for \( \xi \in \{0, 1\} \), hence \( x^\xi - y \) belongs to \( S \) and therefore
\[ |G| \leq \#V(x^\xi - y, x^{d-1} - 1) = d - 1 < \frac{d^2 + d + 1}{2}. \]
Thus we may assume \( 1 < k < d \). We have \( x^k - xy = x(x^{k-1} - y) \), so that \( x^{k-1} - y \) belongs to \( S \) and therefore
\[ |G| \leq \#V(x^{k-1} - y, y^{d-1} - 1) = (k - 1)(d - 1). \]
(5.3)
On the other hand, \( x^d y - x^k = x^k(x^{d-k} - y) \), so that \( x^{d-k} y - 1 \) belongs to \( S \) and therefore
\[ |G| \leq \#V(x^{d-k} y - 1, y^{d-1} - 1) = (d - k)(d - 1). \]
(5.4)
If we sum the inequalities (5.3) and (5.4) we obtain
\[ |G| \leq \frac{(k - 1)(d - 1) + (d - k)(d - 1)}{2} = \frac{(d - 1)^2}{2} < \frac{d^2 + d + 1}{2}. \]
If \( m = y^k \) for some \( k \in \mathbb{N} \), the proof follows as above. Thus, we can assume that \( m = x^k y^l \) with \( k, l \geq 1, k + l \leq d + 1 \). We can suppose \( k \geq l \); the other case is quite similar. Then, since \( m \neq xy \), we have \( k > 1 \). Then \( x^k y^l - xy = (x^{k-1} y^{l-1} - 1) \), so \( x^{k-1} y^{l-1} - 1 \) belongs to \( S \) and therefore
\[ |G| \leq \#V(x^{k-1} y^{l-1} - 1, y^{d-1} - 1) = (k - 1)(d - 1). \]
(5.5)
Since \( m \neq x^d y \), we have \( k < d \). Then \( x^d y - x^k y^l = x^k y(x^{d-k} - y^{l-1}) \), so \( x^{d-k} y^{l-1} \) belongs to \( S \) and therefore
\[ |G| \leq \#V(x^{d-k} y^{l-1} - 1, y^{d-1} - 1) = (d - k)(d - 1). \]
(5.6)
Finally, as above the result follows by summing (5.5) and (5.6).

\[ \square \]

**Proof of Lemma 5.3.** By Bézout’s Theorem the lemma holds for \( |S| \leq 2 \). Assume that Lemma holds if \( |S| \leq k \in \mathbb{N} \). Suppose now that \( |S| = k + 1 \) and fix any \( f \in S \). Write
\[ S = \{f_1, \ldots, f_{k+1}\} \]
with \( f_1 = f \). We can put \( f_1 = hg_1, \ldots, f_k = hg_k \), where \( h \) is the greatest common divisor of the \( f_j \); so the set \( V(g_1, \ldots, g_k) \) is finite and by the inductive hypothesis
\[ |V(g_1, \ldots, g_k)| \leq N \deg g_1. \]
Observe that
\[ V(S) \subset V(h, f_{k+1}) \cup V(g_1, \ldots, g_k). \]
Clearly \( h \) and \( f_{k+1} \) have no common factor, otherwise \( V(S) \) would be infinite. Then, by Bézout’s Theorem we have
\[ |V(h, f_{k+1})| \leq \deg f_{k+1} \deg h \leq N \deg h \]
and therefore
\[ |V(S)| \leq |V(h, f_{k+1})| + |V(g_1, \ldots, g_k)| \leq N \deg h + N \deg g_1 = N \deg f. \]

\[ \square \]
6. Transitive imprimitive groups

This section is devoted to prove Proposition 4.4 and Proposition 4.5. We need the following lemma whose proof is easily obtained and so we omit it.

**Lemma 6.1.** Consider the polynomial 1-form with isolated singularities on $\mathbb{C}^2$ given by

$$\omega = \sum_{i,j \geq 0} \alpha_{ij} x^i y^j dx + \sum_{i,j \geq 0} \beta_{ij} x^i y^j dy,$$

where $\alpha_{ij}, \beta_{ij} \in \mathbb{C}$. Let $\mathcal{F}$ be the holomorphic foliation defined by $\omega$ on $\mathbb{C}^2$ and suppose that $\mathcal{F}$ is invariant by the transformation

$$R:[x:y:z] \mapsto [\mu y: \nu x: z],$$

where $\mu, \nu \in \mathbb{C}^*$. Then, $\alpha_{ij}$, $\beta_{ij} \in \mathbb{C}^+$. Hence

$$\text{Proof of Proposition 4.4.}$$

Let $G < \text{Aut}(\mathcal{F})$ be the subgroup of transformations of the form

$$[x:y:z] \mapsto [ax: by: z].$$

It is not difficult to see that $[\text{Aut}(\mathcal{F}) : G] = 3$. Then by Proposition 4.2 we obtain

$$|\text{Aut}(\mathcal{F})| = 3|G| \leq 3(d^2 + d + 1).$$

Suppose that the inequality above is an equality. Then, by Proposition 4.2 we have that $\mathcal{F}$ is defined by the 1-form

$$\omega = (\alpha + \rho x^d y)dx + (\beta y^d - \rho x^{d+1})dy$$

for some $\alpha, \beta, \rho \in \mathbb{C}^+$. Since $\mathcal{F}$ is invariant by the transformation

$$[x:y:z] \mapsto [y:z:x],$$

by substituting $(x,y) \leftarrow (y/x, 1/x)$ in $\omega$ we obtain a meromorphic 1-form $\tilde{\omega}$ such that

$$x^{d+2} \tilde{\omega} = x^{d+2} \left( \left[ \alpha + \rho(y/x)^d (1/x) \right] \frac{x dy - y dx}{x^2} - \left[ \beta (1/x)^d - \rho(y/x)^{d+1} \right] \frac{dx}{x^2} \right)$$

$$= (-\beta - \alpha x^d y) dx + (\rho y^d + \alpha x^{d+1}) dy,$$

hence $-\beta = \theta \alpha$, $-\alpha = \theta \beta$, $\rho = \theta \beta$ and $\alpha = -\theta \rho$ and therefore $\theta^3 = 1$, $\alpha = -\theta \rho$ and $\beta = \theta^2 \rho$. From this we conclude that $\mathcal{F}$ is defined by the 1-form

$$\omega_\theta = (x^d y - \theta) dx + (\theta^2 y^d - x^{d+1}) dy,$$

where $\theta^3 = 1$. Take $a, b \in \mathbb{C}^+$ such that $\theta^{d+1} = \theta^{1-d}$ and $a = \theta^d b^{d+1}$, and consider the map $f(x, y) = (ax, by)$. A direct computation shows that

$$f^*(\omega_\theta) = (a^{d+1} bx^d y - a \theta a) dx + (\theta^2 y^{d+1} y^d - a^{d+1} bx^{d+1}) dy$$

$$= \theta^2 b^{d+1} \left[ (x^d y - 1) dx + (y^d - x^{d+1}) dy \right],$$

so the foliation $\mathcal{F}$ is equivalent to the Jouanolou Foliation of degree $d$. \(\square\)

**Proof of Proposition 4.5.** Let $\omega = Adx + Bdy$ be a polynomial 1-form with isolated singularities defining $\mathcal{F}$ on $\mathbb{C}^2 = \{[x:y:1]: x, y \in \mathbb{C}\}$. Let $G < \text{Aut}(\mathcal{F})$ be the subgroup of transformations of the form

$$[x:y:z] \mapsto [ax: by: z].$$

It is not difficult to see that $[\text{Aut}(\mathcal{F}) : G] = 6$. Suppose that the line at infinity $z = 0$ is invariant by $\mathcal{F}$. Since the three lines $x = 0$, $y = 0$ and $z = 0$ are permuted by

$$T: [x:y:z] \mapsto [y:z:x] \text{ and } R: [x:y:z] \mapsto [\mu y: \nu x: z]$$

which leave $\mathcal{F}$ invariant, then the three lines $x = 0$, $y = 0$ and $z = 0$ are invariant by $\mathcal{F}$. The invariance of the line $y = 0$ means that $A(x, 0) = 0$. Thus, since $\omega$ has isolated singularities the polynomial $B(x, 0)$ is not zero, so we have

$$B(x, y) = c_k x^k + \cdots + c_1 x^1 + O(y), \quad (6.1)$$
where \(0 \leq k \leq l \leq d, c_0 \neq 0, c_0 \neq 0\). If we denote \(L = \{y = 0\}, 0 := [0 : 0 : 1]\) and \(\infty = [1 : 0 : 0]\), from equation (6.1) we have that
\[
Z(\mathcal{F}, L, 0) = k, \ Z(\mathcal{F}, L, \infty) = d + 1 - l,
\]
where \(Z\) denote the index defined in in [4, p.15] which coincides the Gomez-Mont-Seade-Verjovsky index [10]. Indeed \(Z(\mathcal{F}, L, 0)\) is the vanishing order of \(B(x, 0)\) and \(Z(\mathcal{F}, L, \infty)\) is the vanishing order of
\[
z^{d+1}B \left( \frac{1}{z}, 0 \right) = c_k z^{d+1-k} + \cdots + c_1 z^{d+1-\ell}.
\]
Observe that \(R \circ T\) leave \(L\) invariant and maps \(0\) to \(\infty\). Thus, since \(\mathcal{F}\) is invariant by \(R \circ T\) we have that
\[
Z(\mathcal{F}, L, 0) = Z(\mathcal{F}, L, \infty),
\]
hence
\[
k + l = d + 1,
\]
and therefore
\[
k \leq \frac{d + 1}{2}.
\]
From (6.1) we see that the monomial \(x^k y^l\) appear in \(\omega\) with a nonzero coefficient and, by Lemma 6.1, the same happens with \(y^l dx\). Then the monomials \(x^k y^l\) and \(xy^k\) are contained in \(M\) and therefore the difference \(x^k y^l - xy^k\) generates the element \(x^{k-1} - y^{k-1}\) in \(S\) if \(k > 1\), or the element \(y - x\) in \(S\) if \(k = 0\). Anyway, if we assume \(k \neq 1\), the monomial \(x^{k-1} - y^{k-1}\) belongs to \(S\); we leave the case \(k = 1\) for later. It follows from Lemma 5.4 that for all transformation \(g(x, y) = (ax, by)\) in \(G\) we have that
\[
a^{k-1} = b^{k-1}.
\]
Moreover, if \(g \in G\) then
\[
T \circ g \circ T^{-1} : (x, y) \mapsto \left( \frac{b}{a} x, \frac{1}{a} y \right)
\]
also belongs to \(G\), so by equation (6.4) we have
\[
(b/a)^{k-1} = (1/a)^{k-1}
\]
and therefore
\[
a^{k-1} = b^{k-1} = 1,
\]
for all \(g \in G\). It follows from these equations that \(|G| \leq |k - 1| \cdot |k - 1|\) and together with inequality (6.3) we obtain
\[
|\text{Aut}(\mathcal{F})| \leq 6|k - 1|^2 \leq 6 \left( \frac{d-1}{2} \right)^2 < 3(d^2 + d + 1).
\]
Suppose now that \(k = 1\). Then by equation (6.2) we have \(l = d\). From equation (6.1) the monomial \(xyz\) appear in \(\omega\) with a nonzero coefficient and, by Lemma 6.1, the same happens for the monomials \(y^d dx\) and \(y^d dx\). Then the monomials \(xy, x^2 y\) and \(xy^2\) are contained in \(M\). If \(M\) contains some other monomial, by Lemma 5.4 we have
\[
|G| < \frac{d^2 + d + 1}{2},
\]
so that
\[
|\text{Aut}(\mathcal{F})| < 3(d^2 + d + 1).
\]
Then assume that
\[
M = \{xy, x^d y, xy^d\}.
\]
Therefore, again by Lemma 5.4 we obtain
\[
|\text{Aut}(\mathcal{F})| = 6(d-1)^2.
\]
We shall determine the possibilities for \(\omega\). From equation (6.5) we see that, besides \(xy, x^d y, y^d dx\) and \(y^d dx\), the form \(\omega\) could contain the monomials \(x^{d-3} ydx\) and \(xy^{d-1} dy\), so that, up to multiplication by a nonzero complex number, we can write
\[
\omega = ydx + py^d dx + qx^{d-1} ydx + axdy + bx^d dy + cxy^{d-1} dy,
\]
where $p, q, a, b, c \in \mathbb{C}$ and $p, a, b \in \mathbb{C}^*$. Since $\mathcal{F}$ is invariant by the transformation $T$, by substituting $(x, y) \leftarrow (y/x, 1/x)$ in $\omega$ we obtain a form $\tilde{\omega}$ such that $x^{d+2}\tilde{\omega} = \theta \tilde{\omega}$ for some $\theta \in \mathbb{C}^*$. By a direct computation we obtain

$$x^{d+2}\tilde{\omega} = (-p - c)ydx + (q - b)y^d \tilde{\omega} + (-a - 1)x^{d-1}ydx + px dy + x^d dy + qxy^{d-1}dy,$$

so we have

$$-p - c = \theta, -q - b = \theta p, -a - 1 = \theta q, p = \theta a, 1 = \theta b, q = \theta c.$$  \hspace{1cm} (6.7)

By substituting $q = -\theta^{-1}(a + 1), p = \theta a$ and $b = \theta^{-1}$ in the second equation above we have

$$\theta^{-1}(a + 1) - \theta^{-1} = \theta^2 a,$$

so that $\theta^3 = 1$. Then we find that the equations (6.7) are equivalent to

$$q = -\theta^2(a + 1), p = \theta a, b = \theta^2, c = -\theta(a + 1), a \in \mathbb{C}^*,$$

so that $\omega$ is given by

$$\omega_{\theta, a} = ydx + \theta ay^d dx - \theta^2(a + 1)x^{d-1}ydx + axdy + \theta^2 x^d dy - \theta(a + 1)xy^{d-1}dy.$$

Since $\mathcal{F}$ is invariant by $R$, if we do the substitution $(x, y) \leftarrow (\mu y, \nu x)$ in $\omega_{\theta, a}$ we must obtain a form $\tilde{\omega}$ such that $\tilde{\omega} = \omega_{\lambda \theta, \theta a}$ for some $\lambda \in \mathbb{C}^*$. A simple computation gives

$$\tilde{\omega} = \nu \mu xdy + \nu^d \mu \theta ax^d dy - \mu^d \nu \theta^d(a + 1)y^{d-1}xdy + \nu \mu ydx + \mu^d \theta^d y^d dx - \nu^d \mu \theta(a + 1)yx^{d-1}dx,$$

so that

$$\nu \mu = \lambda a, \nu^d \mu \theta a = \lambda \theta^2, -\mu^d \nu \theta^2(a + 1) = -\lambda \theta(a + 1),$$

$$\nu \mu a = \lambda, \nu^d \mu \theta^2 = \lambda \theta a, -\nu^d \mu \theta(a + 1) = -\lambda \theta^2(a + 1).$$

from $\nu \mu = \lambda a$ and $\nu \mu a = \lambda$ we obtain $a = \pm 1$. Suppose first that $a = -1$. Then the system (6.8) becomes

$$\nu \mu = -\lambda, \nu^{d-1} = \theta^2, \mu^{d-1} = \theta^2.$$

Thus, in this case the form $\omega$ effectively exists and is given by

$$\omega_{-1, \theta} = ydx - \theta y^d dx - xdy + \theta^2 x^d dy.$$

By substituting $(x, y) \leftarrow (ax, \beta y)$, $a^{d-1} = \theta, \beta^{d-1} = \theta^2$ in the form above we obtain the form

$$\alpha \beta \left[ ydx - y^d dx - xdy + x^d dy \right]$$

and therefore $\mathcal{F}$ is isomorphic to the foliation $\mathcal{F}_a$. Suppose now that $a = 1$. Then the system (6.8) becomes

$$\nu \mu = \lambda, \nu^{d-1} = \theta, \mu^{d-1} = \theta^2$$

and we obtain

$$\omega_{1, \theta} = ydx + \theta y^d dx - \theta^2 x^{d-1}ydx + xdy + \theta^2 x^d dy - 2\theta xy^{d-1}dy.$$

Again, by substituting $(x, y) \leftarrow (ax, \beta y), a^{d-1} = \theta, \beta^{d-1} = \theta^2$ we obtain the form

$$\alpha \beta \left[ ydx + y^d dx - 2x^{d-1}ydx + xdy + x^d dy - 2xy^{d-1}dy \right],$$

so that $\mathcal{F}$ is isomorphic to $\mathcal{G}_a$. This finishes the proof of the part (1) of Proposition 4.3.

Now, assume that the line at infinity $L_{\infty} = \{z = 0\}$ is generically transverse to $\mathcal{F}$. Then the line $y = 0$ is also generically transverse to $\mathcal{F}$, so that $A(x, 0)$ is not zero. Therefore

$$A(x, 0) = c_k x^k + O(x^{k+1})$$

with $c_k \neq 0, k \geq 0$, so that $\omega$ contains the monomial $x^k dx$ and, by Lemma 6.1, also the monomial $y^k dy$. It follows from Proposition 5.2 that for all transformation $g(x, y) = (ax, by)$ in $G$ we have

$$a^{k+1} = b^{k+1}.$$  \hspace{1cm} (6.9)

Thus, since $T g T^{-1} : (x, y) \mapsto \left(\frac{a}{b}x, \frac{1}{b}y\right)$ also belongs to $G$ we have

$$(b/a)^{k+1} = (1/a)^{k+1}$$

and therefore

$$a^{k+1} = b^{k+1} = 1.$$  \hspace{1cm} (6.10)
From these equations we obtain $|G| \leq (k+1)(k+1)$ and consequently

$$|\text{Aut}(\mathcal{F})| \leq 6(k+1)^2. \quad (6.11)$$

Observe that $k$ is the tangency order of $\mathcal{F}$ to $L = \{ y = 0 \}$ at $0 = [0 : 0 : 1]$. Since $R \circ T$ leave $L$ invariant and maps 0 to $\infty = [1 : 0 : 0]$, we have

$$\text{Tang}(\mathcal{F}, L, 0) = \text{Tang}(\mathcal{F}, L, \infty) = k. \quad (6.12)$$

Thus, since the total tangency of $\mathcal{F}$ to the line $L$ is exactly $d$, we conclude that $k \leq d/2$. Then, from Equation $(6.11)$ we have

$$|\text{Aut}(\mathcal{F})| \leq 6 \left( \frac{d}{2} + 1 \right)^2,$$

so we obtain

$$|\text{Aut}(\mathcal{F})| < 3(d^2 + d + 1) \quad (6.13)$$

for all $d > 2$. Thus, to continue with the remaining case we assume $d = 2$. Then we have $k \in \{0, 1\}$. If $k = 0$, Equation $(6.11)$ gives $|\text{Aut}(\mathcal{F})| = 6 < 3(d^2 + d + 1)$. Then we may assume $k = 1$ and therefore $\omega$ contains the monomials $xdx$ and $ydy$ with nonzero coefficients. Since $\mathcal{F}$ is generically transverse to the line at infinity $L_\infty$, the homogeneous part of maximum degree of $\omega$ has the form

$$Q(ydx - xdy),$$

where $Q \in \mathbb{C}[x, y]$ is homogeneous of degree 2. From $(6.12)$ and the symmetries of $\mathcal{F}$ we deduce that $\mathcal{F}$ has nonzero tangency orders with $L_\infty$ at the points $[0 : 1 : 0]$ and $[1 : 0 : 0]$. This means that $x$ and $y$ are factors of $Q$, so we have that $Q = cxy$ for some $c \in \mathbb{C}^*$. Clearly we can assume that $c = 1$. Then $\omega$ contains the monomials $xy^2dx$ and $-x^2ydy$. We deduce that the set of monomials $\mathcal{M}$ - as defined in Section 5 - contains

$$\mathcal{M} = \langle x^2, y^2, x^2y^2 \rangle.$$ 

Let us prove that $\mathcal{M} = \mathcal{M}$ implies $|\text{Aut}(\mathcal{F})| < 3(d^2 + d + 1)$. Observe that $\mathcal{M} \setminus \mathcal{M}$ can only contain monomials of degrees 2 or 3, so we have

$$\mathcal{M} \setminus \mathcal{M} \subset \langle xy, x^3, y^3, x^2y, xy^2 \rangle.$$ 

For example, suppose that $xy \in \mathcal{M}$. Then $xy - y^2$ and $x^2y^2 - y^2$ generate the elements $x - y$ and $x^2 - 1$ in the set $\mathcal{S} -$ as defined in Section 5. Then

$$|G| \leq \#V(x - y, x^2 - 1) = 2,$$

so that

$$|\text{Aut}(\mathcal{F})| \leq 12 \times 3(d^2 + d + 1).$$

The analysis for each of the other possible monomials in $\mathcal{M} \setminus \mathcal{M}$ is quite similar. Then we can assume

$$\mathcal{M} = \langle x^2, y^2, x^2y^2 \rangle$$

and therefore $\omega$ has the form

$$\omega = (ax + xy^2)dx + (by - x^2y)dy,$$

where $a, b \in \mathbb{C}^*$. Since $\mathcal{F}$ is invariant by the transformation $T$, by substituting $(x, y) \leftrightarrow (y/x, 1/x)$ in $\omega$ we obtain a form $\tilde{\omega}$ such that $x^4\tilde{\omega} = \theta \omega$ for some $\theta \in \mathbb{C}^*$. By a direct computation we have

$$x^4\tilde{\omega} = (-bx - axy^2)dx + (y + ax^2y)dy,$$

so that $-b = \theta a$, $-a = \theta$, $1 = \theta b$ and we obtain $\theta^3 = 1$, $a = -\theta$, $b = \theta^2$. Then

$$\omega = (-\theta x + xy^2)dx + (\theta^2 y - x^2y)dy.$$

By substituting $(x, y) \leftrightarrow (ax, \beta y)$, $a^2 = \theta^2$, $\beta^2 = \theta$ in the form above we obtain

$$(-x + xy^2)dx + (y - x^2y)dy$$

and therefore $\mathcal{F}$ is isomorphic to the foliation $\mathcal{S}$. \qed
7. Polyhedral groups

This section is devoted to prove Proposition 4.3. We begin with some definitions. Let \( F \) be a complex polynomial in two variables, let \( \omega \) be a polynomial 1-form in two variables and let \( G \) be a subgroup of \( GL(2, \mathbb{C}) \). We say that \( F \) is semi-invariant by \( g \in GL(2, \mathbb{C}) \) if there exist a constant \( \lambda \in \mathbb{C}^* \) such that \( F(g) := F \circ g = \lambda F \). Similarly, the 1-form \( \omega \) is semi-invariant by \( g \in GL(2, \mathbb{C}) \) if there exist a constant \( \lambda \in \mathbb{C}^* \) such that \( g^*(\omega) = \lambda \omega \). We say that \( F \) (resp. \( \omega \)) is \( G \)-semi-invariant if \( F \) (resp. \( \omega \)) is semi-invariant by every \( g \in G \). We say that the 1-form \( \omega \neq 0 \) is homogeneous of degree \( n \), if we have \( \omega = Adx + Bdy \), where \( A \) (resp. \( B \)) is a homogeneous polynomial of degree \( n \) or \( A = 0 \) (resp. \( B = 0 \)).

As we have seen in Subsection 4.2 in suitable homogeneous coordinates \( (X : Y : Z) \) the group \( Aut(F) \) preserves \( \{Z = 0\} \) hence it corresponds finite non abelian subgroup \( G \) of \( GL(2, \mathbb{C}) \) acting on the affine chart \( \{Z \neq 0\} \) with natural coordinates \((x, y)\). Moreover we have that its image \( G \subset \text{PGL}(2, \mathbb{C}) \) is a polyhedral group. The foliation \( \mathcal{F} \) is defined as a \( G \)-semi-invariant polynomial 1-form \( \omega \), which can be expressed as a sum

\[
\omega = \sum_{j \in J} \omega_j,
\]

where \( J \subset \{0, \ldots, d+1\} \) and each \( \omega_j \) is homogeneous of degree \( j \). Observe that the origin \( 0 \in \mathbb{C}^2 \) need to be a singularity of \( \mathcal{F} \), otherwise the tangent line to \( \mathcal{F} \) at the origin would define a fixed point of \( G \), which is impossible because \( G \) is a polyhedral group. Then we have \( J \subset \{1, \ldots, d+1\} \). Moreover, notice that \(|J| \geq 2\), otherwise \( \omega \) would be homogeneous and \( Aut(\mathcal{F}) \) would be infinite. Given any \( g \in G \), there exists a constant \( \lambda \in \mathbb{C}^* \) such that

\[
\sum_{j \in J} g^*(\omega_j) = \lambda \sum_{j \in J} \omega_j.
\]

Then, since \( g \) is linear we necessarily have

\[
g^*(\omega_j) = \lambda \omega_j
\]

for all \( j \in J \), from which we conclude that each \( \omega_j \) is \( G \)-semi-invariant.

**Lemma 7.1.** Let \( \omega \neq 0 \) be a homogeneous 1-form of degree \( n \) in two variables. Then we can express

\[
\omega = dP + Q(xdy - ydx),
\]

where \( P \) and \( Q \) are homogeneous of degrees \( n+1 \) and \( n-1 \) respectively. Moreover if \( \omega \) is \( G \)-semi-invariant for some \( G \subset GL(2, \mathbb{C}) \) then so are \( P \) and \( Q \).

**Proof.** Let \( \omega = Adx + Bdy \) and define \( P = \frac{1}{n+1}(Ax + By) \) and \( Q = \frac{1}{n+1} \left( \frac{\partial A}{\partial y} - \frac{\partial B}{\partial x} \right) \). A straightforward computation – we only need to use the relations \( nA = x \frac{\partial A}{\partial y} + y \frac{\partial A}{\partial x} \) and \( nB = x \frac{\partial B}{\partial y} + y \frac{\partial B}{\partial x} \) – shows that \( \omega = dP + Q(xdy - ydx) \). It remains to prove that \( P \) and \( Q \) are \( G \)-semi-invariant if so is \( \omega \). Let \( g(x, y) = (ax + by, cx + dy) \in G \). Since \( g^*(\omega) = \lambda \omega \) for some \( \lambda \in \mathbb{C}^* \), we have

\[
A(g)d(ax + by) + B(g)d(cx + dy) = \lambda Adx + \lambda Bdy,
\]

so that

\[
A(g)a + B(g)c = \lambda A,
A(g)b + B(g)d = \lambda B.
\]

Then

\[
P(g) = \frac{1}{n+1} [A(g)(ax + by) + B(g)(cx + dy)] = \lambda P
\]

and therefore \( P \) is semi-invariant by \( g \). From the last equation we obtain

\[
g^*(dP) = d \left( P(g) \right) = \lambda dP,
\]

so \( dP \) is semi-invariant by \( g \). Then \( Q(xdy - ydx) = \omega - dP \) is semi-invariant by \( g \) and from this we easily obtain that \( Q \) is semi-invariant by \( g \). \( \square \)
Now we continue with the proof of Proposition 4.3. The group $\Gamma$ is the quotient of $G$ by its subgroup $H$ of homotheties. We will relate the order of $H$ with the degree of the foliation. If $|H| = n$, we have that $H$ is generated by an element of the form $h = \xi I$, where $\xi$ is a primitive $n$th-root of unity. Since $\omega$ is semi-invariant by $h$ there exist $c \in \mathbb{C}^*$ such that

$$\sum_j \xi^{j+1} \omega_j = c \sum_j \omega_j.$$  

Then $\xi^{j+1} = c$ for all $j \in J$. Thus, if $j_1 < j_2$ are elements in $J$, we have $\xi^{j_2-j_1} = 1$ and therefore $n \leq j_2 - j_1$. We conclude that

$$|H| \leq |j_2 - j_1|, \forall j_1, j_2 \in J \text{ distinct.} \quad (7.1)$$

In particular we obtain

$$|H| \leq d$$

that together with our assumption $3(d^2 + d + 1) \leq |G|$ leads to

$$3(d^2 + d + 1) \leq |G| = |\Gamma| |H| \leq |\Gamma| d. \quad (7.2)$$

According to Lemma 4.1, we can express $\omega_j = dP_j + Q_j(x dy - y dx)$ for each $j \in J$. Notice the following facts:

1. If $d + 1 \in J$, then $P_{d+1}$ is zero: if $\omega_{d+1} \neq 0$, the foliation is generically transverse to the line at infinity and we have $\omega_{d+1} = Q(x dy - y dx)$ for some homogeneous polynomial $Q$. If this were the case, we would have

$$dP_{d+1} + Q_{d+1}(x dy - y dx) = Q(x dy - y dx)$$

and it is easy to see that this would imply that $P_{d+1} = 0$.

2. The polynomial $P_j$ is not zero for some $j \in J$. Otherwise $F$ would be the radial foliation $x dy - y dx = 0$ and $\text{Aut}(F)$ would be infinite.

First recall that for any finite subgroup $\Gamma \subset \text{PGL}(2, \mathbb{C})$ the stabilizer $\Gamma_p$ of any point $p \in \mathbb{P}^1$ is cyclic. Then the smallest orbits of such group correspond to its elements with largest order. We refer to Klein’s book [12] for generalities on the polyhedral groups.

Case 1: suppose that $\Gamma = T$ the tetrahedral group. Since $|T| = 12$, Inequality (7.2) implies that $d = 2$. Take $j' \in J$ such $P_{j'} = 0$. By the fact 1 above we have $j' \leq d = 2$, so that $\deg P_{j'} \leq 3$. Then $P_{j'} = 0$ defines a set of order $\leq 3$ in $\mathbb{P}^1$ which is invariant by the action of $T$; but this is a contradiction because the smallest orbit of $T$ in $\mathbb{P}^1$ has order 4.

Case 2: suppose that $\Gamma = O$ the octahedral group. The smallest orbit of $O$ has order 6 and it is well known that, up to linear change of coordinates, we can assume that this orbit corresponds to the 6 lines defined by the polynomial

$$P = xy(x^4 - y^4).$$

Since $|O| = 24$, Inequality (7.2) implies that $d \leq 6$. Take $\omega_{j'} = dP_{j'} + Q_{j'}(x dy - y dx)$ with $P_{j'} = 0$. By the fact 1 above we have $j' \leq d \leq 6$, so that $\deg P_{j'} \leq 7$. Thus, since $P_{j'} = 0$ defines a finite set in $\mathbb{P}^1$ which is invariant by $O$ and the smallest orbits of $O$ have orders 6 and 8, we conclude that $\deg P_{j'} = 6, j' = 5$ and any other $P_j$ is zero. Moreover, since $P_5$ has degree 6 and $P_5 = 0$ has to be an equation of the 6 lines composing the orbit of order 6 of $O$, we have $P_5 = \beta P$ for some $\beta \in \mathbb{C}^*$. Observe that $Q_5 = 0$, otherwise $Q_5 = 0$ would define a set of order $\leq 6$ which would be invariant by $O$. Then $\omega_5 = \beta dP$, hence $d \geq 5$ and from Inequality (7.2) we obtain that $|H| \geq 4$. Then, from Inequality (7.1) we deduce that the only other $\omega_j \neq 0$ that can exist – and actually exists because $\omega$ is not homogeneous – is $\omega_1$. Since $P_1$ is zero, we have $\omega_1 = \alpha (x dy - y dx)$ for some $\alpha \in \mathbb{C}^*$ and therefore

$$\omega = \alpha (x dy - y dx) + \beta dP.$$  

Applying the substitution $(x, y) \rightarrow (\lambda x, \lambda y)$ with $\lambda^4 = \alpha/\beta$ we obtain the 1-form

$$\alpha \lambda^2 (x dy - y dx + dP),$$

so that $\mathcal{F} = P_5$. 

Case 3: suppose that $G = I$ the icosahedral group. The smallest orbit of $O$ has order 12 and it is well known that, up to linear change of coordinates, we can assume that this orbit corresponds to the 12 lines defined by the polynomial

$$P = xy(x^{10} + 11x^5y^5 - y^{10}).$$

Since $|I| = 60$. Inequality (7.2) implies that $d \leq 18$. Take $\omega' = dP_{j'} + Q_{j'}(x \, dy - y \, dx)$ with $P_{j'} \neq 0$. By the fact above we have $j' \leq d \leq 18$, so that $\deg P_{j'} \leq 19$. Thus, since $P_{j'} = 0$ defines a finite set in $\mathbb{P}^1$ which is invariant by $I$ and the smallest orbits of $I$ have orders 12 and 20, we conclude that $\deg P_{j'} = 12$, $j' = 11$ and any other $P_j$ is zero. Moreover, since $P_{11}$ has degree 12 and $P_{11} = 0$ is an equation of the 12 lines composing the orbit of order 12 of $I$, we have $P_{11} = \beta P$ for some $\beta \in \mathbb{C}^*$. Recall that $Q_j = 0$ defines a set of order $\deg Q_j = j - 1 \leq d \leq 18$ in $\mathbb{P}^1$, which is invariant by $I$. Thus, since the smallest orbits of $I$ have orders 12 and 20, we necessarily have $\deg Q_j \in \{0, 12\}$. If $\deg(Q_j) = 12$, we have that $\omega_{13} \neq 0$ and, since $\omega_{11}$ is also non-zero, Inequality (7.2) gives $|I| \leq 2$, which together with Inequality (7.2) gives $d \leq 5$, a contradiction. Thus we can only have $\deg(Q_j) = 0$, so that the unique other $\omega_j$ that can exist – and actually exists because $\omega$ is not homogeneous – is $\omega_1$. Since $P_1$ is zero, there exists $\alpha \in \mathbb{C}^*$ such that

$$\omega = \alpha(x \, dy - y \, dx) + \beta dP.$$

Applying the substitution $(x, y) \rightarrow (\lambda x, \lambda y)$ with $\lambda^{10} = \alpha/\beta$ we obtain the 1-form

$$\alpha \lambda^2 (x \, dy - y \, dx + dP),$$

so that $\mathcal{F} = \mathcal{P}_{11}$. □

8. **Poincaré series and a Molien-type formula**

To study the foliations invariant by a primitive subgroup of $\text{PGL}(3, \mathbb{C})$ we change our approach to a more direct one through representations of these groups. We refer to [13] for the basic results of Invariant Theory.

Let $M = \bigoplus_{d \geq 0} M_d$ be a graded vector space such that $\dim_{\mathbb{C}}(M_d) < \infty$ for each $d$. The Poincaré series of $M$ is defined by

$$P(M; t) = \sum_{d \geq 0} \dim_{\mathbb{C}}(M_d) t^d.$$  

When $M$ is a finitely generated module over a complex polynomial ring, the Hilbert-Serre theorem says that $P(M; t)$ is a rational function of the variable $t$. Given a finite group $G$, a graded $G$-module $M$ and a character $\chi : G \rightarrow \mathbb{C}^{*}$, the Reynolds operator $\mathcal{R}_\chi : M \rightarrow M$ is defined by

$$\mathcal{R}_\chi(m) = \frac{1}{|G|} \sum_{g \in G} \chi(g^{-1}) \cdot m, \ m \in M.$$  

It is an idempotent graded operator whose image is the submodule $M^\chi$ of $G$-semi-invariants with character $\chi$. In particular, the dimension of each homogeneous component of $M^\chi$ is given by the trace of the appropriate restriction of $\mathcal{R}_\chi$. For instance, let $M = \mathbb{C}[X_0, \ldots, X_n]$. For a faithful representation $G \rightarrow \text{GL}(n + 1, \mathbb{C})$ Molien’s formula exhibits the rational function:

$$P(M^\chi; t) = \frac{1}{|G|} \sum_{g \in G} \chi(g) \det(tI - lg).$$  \hspace{1cm} (8.1)

Given a finite subgroup $G < \text{GL}(3, \mathbb{C})$ and a character $\chi : G \rightarrow \mathbb{C}^{*}$, we want to describe the homogeneous vector fields $\nu$ on $\mathbb{C}^3$ with $\text{div}(\nu) = 0$ that are $G$-semi-invariant – see Section 2. Since the arguments are valid in any dimension, we state and prove our main result for a finite dimensional vector space $W$. Suppose that $G < \text{GL}(W)$ is a finite group. Thus, we are interested in the $G$-module $V$ of polynomial vector fields whose divergence is zero. The action is given by the pushforward and the grading is given by the degree. Recall that when $W = \mathbb{C}^3$ a degree $d$ foliation on $\mathbb{P}^2$ is defined by an element of $V_d$ that is unique up to scalar multiplication. The following theorem is a Molien-type formula.
Let $W$ be a finite dimensional vector space, let $G < \text{GL}(W)$ be a finite group and let $\chi : G \to \mathbb{C}^*$ be a character. Then
\[
P(V^\chi; t) = \frac{1}{|G|} \sum_{\varphi \in G} \chi(\varphi) (\text{tr}(\varphi^{-1}) - t) \det(I - t\varphi).
\]

**Proof.** First notice that the space of homogeneous polynomials of degree $d$ on $W$ is naturally identified with $S^d(W^\vee)$, the symmetric power of the dual space. The space of degree $d$ homogeneous vector fields is naturally identified with $S^d(W^*) \otimes W$. Let $v \in S^d(W^*) \otimes W$ be a homogeneous vector field. For any $\varphi \in \text{GL}(W)$ we have $\text{div}(\varphi_* v) = \text{div}(v) \circ \varphi^{-1}$. Then $V_d$ is a $\text{GL}(W)$-submodule of $S^d(W^*) \otimes W$. On the other hand, for a homogeneous polynomial $P$ we have $\varphi_* (PR) = (P \circ \varphi^{-1})R$, where $R$ is the radial vector field. This gives us the exact sequence of $\text{GL}(W)$-modules
\[
0 \to S^{d-1}(W^*) \to S^d(W^*) \otimes W \to V_d \to 0. \tag{8.2}
\]

Proof continued on the next page...
9. Primitive groups

This section is devoted to prove propositions 4.3 and 4.4. Let $\text{Aut}(\mathcal{F}) < \text{PGL}(3, \mathbb{C})$ be a transitive primitive group. We can take a finite group $G < \text{GL}(3, \mathbb{C})$ whose image in $\text{PGL}(3, \mathbb{C})$ is equal to $\text{Aut}(\mathcal{F})$. Let $v$ be a homogeneous vector field in $\mathbb{C}^3$ with $\text{div}(v) = 0$ that induces $\mathcal{F}$. Then $v$ is $G$-semi-invariant. Note that this works for any choice of $G$ since $v$ is homogeneous.

In the following subsections we analyze each of the possibilities – described in the subsections 4.3 and 4.5 – for $\text{Aut}(\mathcal{F})$. For each of these cases we use Theorem 5.1 to determine the possible vector fields $v$ such that $|\text{Aut}(\mathcal{F})| \geq 3(d^2 + d + 1)$. After our study, the proofs of the propositions 4.6 and 4.7 will be clearly finished. All representations and character tables come from [3], except for the Hessian group that comes from [4]. We also remark that we have used Maple™ to speed up calculations of the Poincaré series, the same could be achieved in any computer algebra system or even by hand.

9.1. The Hessian Group. To do the computations we will follow [3]. Suppose that $\text{Aut}(\mathcal{F})$ is the Hessian group. Then we can take $G$ equal to the triple cover of order 648 in $\text{GL}(3, \mathbb{C})$ generated by the pseudo-reflections

$$R_1 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & \lambda^2 \end{pmatrix}, R_2 = \frac{1}{\sqrt{-3}} \begin{pmatrix} \lambda & \lambda^2 & \lambda^2 \\ \lambda^2 & \lambda & \lambda^2 \\ \lambda^2 & \lambda^2 & \lambda \end{pmatrix}, R_3 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & 1 \end{pmatrix},$$

where $\lambda$ is a primitive cubic root of unity. The multiplicative characters are determined by their image of any element on the conjugacy class of $R_1$, see [3], hence there are three possibilities: the trivial character $\chi_0(R_1) = 1$ and $\chi_i(R_1) = \lambda^i$ for $i = 1, 2$. Then we compute the functions:

$$P(V^G; t) = \frac{t^{19} + t^{16} + t^{13} + t^{10} + t^7 + t^4}{(1 - t^3)(1 - t^{12})(1 - t^{18})} = t^4 + t^7 + t^{10} + 2t^{13} + 3t^{16} + \ldots$$

$$P(V^{X_1}; t) = \frac{t^{31} + t^{28} + t^{25} + t^{22} + t^{19} + t^{16}}{(1 - t^3)(1 - t^{12})(1 - t^{18})} = t^{16} + t^{19} + 2t^{22} + 2t^{25} + 3t^{28} + \ldots$$

$$P(V^{X_2}; t) = \frac{-t^{37} + t^{28} + t^{25} + t^{22} + 2t^{19} + t^{16} + t^{13}}{(1 - t^3)(1 - t^{12})(1 - t^{18})} = t^{13} + t^{16} + 2t^{19} + \ldots \quad (9.1)$$

The inequality $216 = |\text{Aut}(\mathcal{F})| \geq 3(d^2 + d + 1)$ implies that $d \leq 7$. By the formulas (9.1), the possible degrees are $d = 4, 7$ and there is exactly one foliation with each degree. Then, these foliations are necessarily the Hessian foliations $\mathcal{H}_4$ and $\mathcal{H}_7$.

9.2. The normal subgroup $E$ of the Hessian Group. Suppose that $\text{Aut}(\mathcal{F})$ is the subgroup $E$ of the Hessian group as presented in Subsection 4.3. From the inequality $36 = |\text{Aut}(\mathcal{F})| \geq 3(d^2 + d + 1)$, we see that $d = 2$ is the only possibility. It is not difficult to prove that the orbits in $\mathbb{P}^2$ by the action of $E$ have at least 6 elements. Thus, since $\text{Sing}(\mathcal{F})$ is a union of orbits of $E$ and $|\text{Sing}(\mathcal{F})| \leq d^2 + d + 1 = 7$ we conclude that $\text{Sing}(\mathcal{F})$ is an orbit $\mathcal{O}$ of $E$. Then $\mathcal{F}$ has at least 6 singularities, all of them having the same Milnor number $\mu \in \mathbb{N}$. Since the sum of these Milnor numbers is equal to 7, we necessarily have $\mu = 1$ and $|\mathcal{O}| = 7$, which is a contradiction because 7 does not divide 36. Thus there is no foliation $\mathcal{F}$ satisfying our hypotheses.

9.3. The normal subgroup $F$ of the Hessian Group. Suppose that $\text{Aut}(\mathcal{F})$ is the subgroup $F$ of the Hessian group as presented in Subsection 4.4. From the inequality $72 = |\text{Aut}(\mathcal{F})| \geq 3(d^2 + d + 1)$, we obtain $d \leq 4$. Clearly the set $\mathcal{O}_{12} \subset \mathbb{P}^2$ composed by the twelve singularities of the singular cubics of the Hesse pencil is invariant by $F$ – see [2] for the explicit list of this points. By a straightforward computation we can verify that $\mathcal{O}_{12}$ is actually an orbit of $F$. Observe that the point $[0 : 0 : 1] \in \mathcal{O}_{12}$ is fixed by the subgroup $F_0 \triangleleft F$ generated by $S$ and

$$T^2V^2: [X: Y: Z] \mapsto [Y: X: Z].$$

It is easy to see that $F_0$ does not fix any line through $[0 : 0 : 1]$. Then $[0 : 0 : 1]$ is necessarily a singularity of $\mathcal{F}$, otherwise the tangent line to $\mathcal{F}$ at $[0 : 0 : 1]$ would be fixed.
by $F_0$. Then the twelve points of $O_{12}$ are singularities of $\mathcal{F}$. These singularities are simple because $\mathcal{F}$ has at most $d^2 + d + 1 \leq 21$ singularities counting multiplicities. We can not have $\mathcal{F} = O_{12}$ because the equation $d^2 + d + 1 = 12$ has no solutions. Then $\mathcal{F}$ contains at least one orbit other than $O_{12}$, which has at most nine points. We need the following fact about the group $F$, which is not difficult to prove: the set of nine base points of the Hesse Pencil is an orbit of $F$ – we denoted it by $O_9$ – and any other orbit has more than nine points. Thus, we deduce that $\text{Sing}(\mathcal{F}) = O_9 \cup O_{12}$ and that $\mathcal{F}$ has only simple singularities. Recall that a foliation with simple singularities is determined by its singular set – see [5]. Then, since $\mathcal{H}_4$ has simple singularities and $\text{Sing}(\mathcal{H}_4) = O_9 \cup O_{12}$, we conclude that $\mathcal{F} = \mathcal{H}_4$.

9.4. **The Icosahedral group $A_5$.** This group has a lift to $\text{SL}(3, \mathbb{C})$ that is isomorphic to itself. We can use the following presentation:

$$G = \langle A, B | A^2 = B^3 = (AB)^5 = 1 \rangle$$

with generators

$$A = \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ r & r & 1 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix},$$

where $r$ is the golden ratio $\frac{1 + \sqrt{5}}{2}$. Since $G$ is a simple group, the only possible multiplicative character is the trivial one, hence

$$P(V_G; t) = \frac{-t^{16} + t^{14} + t^{10} + t^6 + t^2}{(1 - t^{10})(1 - t^6)(1 - t^2)} = t^8 + t^7 + t^6 + 2t^5 + \ldots$$

(9.2)

However, the inequality $60 \geq 3(d^2 + d + 1)$ implies $d \leq 3$, so that no foliation is under our hypotheses.

9.5. **The Klein Group $\text{PSL}(2, 7)$.** This group is the celebrated automorphism group of the Klein quartic of equation $X^3Y + Y^3Z + Z^3X = 0$ which attains the Hurwitz bound; it has genus 3 and $168 = 84(g - 1)$ automorphisms. The Klein group is simple and it has a representation in $\text{SL}(3, \mathbb{C})$ given by

$$G = \text{PSL}(2, 7) = \langle A, B | A^2 = B^3 = (AB)^7 = [A, B]^4 = 1 \rangle$$

with generators

$$A = \begin{pmatrix} 1 & -1 & -r \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix},$$

where $r = \frac{-1 + \sqrt{7}}{2}$. Since this group is simple, we only have the trivial character and therefore

$$P(V_G; t) = \frac{-t^{22} + t^{18} + t^{16} + t^{11} + t^9 + t^8}{(1 - t^{14})(1 - t^6)(1 - t^7)} = t^7 + t^6 + t^5 + t^3 + \ldots$$

(9.3)

The inequality $168 \geq 3(d^2 + d + 1)$ implies that $d \leq 6$, so that no foliation satisfies our hypotheses.

9.6. **The Valentinier group $A_6$.** This group has a perfect triple cover in $\text{SL}(3, \mathbb{C})$ of order 1080 given by

$$G = \langle A, B | A^2 = B^4 = (AB)^{15} = (AB^2)^5 = [(AB)^5, A] = 1 \rangle$$

with generators

$$A = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}, \quad B = \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ \alpha & \beta & 1 \end{pmatrix},$$

where $\alpha = -\xi^7 - \xi^{13}, \beta = -\xi^3 - \xi^4$ for some primitive 15th root of unity $\xi$. Although the Valentinier group is not simple, it is perfect – this means $[G, G] = G$. Then we have only the trivial character and therefore

$$P(V_G; t) = \frac{-t^{46} + t^{30} + t^{25} + t^{19} + t^{16}}{(1 - t^{30})(1 - t^{12})(1 - t^6)} = t^{16} + t^{19} + t^{22} + 2t^{25} + \ldots$$

(9.4)
Also in this case there is no foliation under our hypotheses, since the inequality $360 \geq 3(d^2 + d + 1)$ implies $d \leq 10$.
