Department of Neurosurgery, Barrow Neurological Institute, St. Joseph’s Hospital and Medical Center, Phoenix, Arizona

OBJECTIVE The incidence and severity of stroke are disproportionately greater among Black patients. In this study, the authors sought to examine clinical outcomes among Black versus White patients after mechanical thrombectomy for stroke at a single US institution.

METHODS All patients who underwent mechanical thrombectomy at a single center from January 1, 2014, through March 31, 2020, were retrospectively analyzed. Patients were grouped based on race, and demographic characteristics, preexisting conditions, clinical presentation, treatment, and stroke outcomes were compared. The association of race with mortality was analyzed in multivariable logistic regression analysis adjusted for potential confounders.

RESULTS In total, 401 patients (233 males) with a reported race of Black (n = 28) or White (n = 373) underwent mechanical thrombectomy during the study period. Tobacco use was more prevalent among Black patients (43% vs 24%, p = 0.04), but there were no significant differences between the groups with respect to insurance, coronary artery disease, diabetes, illicit drug use, hypertension, or hyperlipidemia. The mean time from stroke onset to hospital presentation was significantly greater among Black patients (604.6 vs 333.4 minutes) (p = 0.007). There were no differences in fluoroscopy time, procedural success (Thrombolysis in Cerebral Infarction grade 2b or 3), hospital length of stay, or prevalence of hemicraniectomy. In multivariable analysis, Black race was strongly associated with higher mortality (32.1% vs 14.5%, p = 0.01). The disparity in mortality rates resolved after adjusting for the average time from stroke onset to presentation (p = 0.14).

CONCLUSIONS Black race was associated with an increased risk of death after mechanical thrombectomy for stroke. The increased risk may be associated with access-related factors, including delayed presentation to stroke centers.

KEYWORDS Black patients; large-vessel occlusion; thrombectomy; stroke

STROKE, the fifth leading cause of death in the United States, has disproportionately affected Black Americans with respect to incidence and severity, for more than 50 years.1–17 According to the REGARDS (Reasons for Geographic and Racial Differences in Stroke) study, only 40% of the disparity in outcomes between Black and White patients is attributable to differences in traditional stroke risk factors, and the reasons for the remaining disparity are unclear.18

Modern mechanical thrombectomy is the gold-standard treatment for acute ischemic stroke caused by large-vessel occlusions.19–25 During the past decade, landmark randomized trials have demonstrated that mechanical thrombectomy is superior to intravenous alteplase alone when performed within 6 hours after onset of stroke symptoms.26 The DAWN (DWI or CTP Assessment With Clinical Mismatch in the Triage of Wake-Up and Late Presenting Strokes Undergoing Neurointervention With
Trevo) trial recently demonstrated an improvement in 90-day disability for patients treated within 6 to 24 hours after stroke onset who had a mismatch between clinical deficit and infarct.\textsuperscript{27} Several studies have demonstrated a racial disparity in the use of thrombectomy and outcomes among patients with acute stroke after an emergent large-vessel occlusion.\textsuperscript{1,28,29} The identification and correction of the sources of this disparity are essential. In this study, we compared stroke outcomes between Black and White patients who underwent mechanical thrombectomy for a stroke at our institution. Furthermore, we investigated potential causes for the disparity in use and outcomes described in earlier literature.

**Methods**

**Study Population**

After institutional review board approval, a retrospective cohort study was performed of patients presenting to St. Joseph’s Hospital and Medical Center in Phoenix, Arizona. Because of the retrospective nature of the study, the need for patient consent was waived. The study population queried was from an institutional data set of all patients who underwent mechanical thrombectomy for acute ischemic stroke at Barrow Neurological Institute (Phoenix, AZ) from January 1, 2014, to March 31, 2020.

**Variables**

The primary predictor variable of interest was race (Black and White). The data set was also reviewed for demographic characteristics (age, sex, and insurance payer status), preexisting conditions (including tobacco, illicit drug, and alcohol use), clinical presentation, and treatment characteristics. Severity of illness was defined according to the National Institutes of Health Stroke Scale (NIHSS) and modified Rankin Scale (mRS) scores at hospital admission. Treatment success was defined as a modified Thrombolysis in Cerebral Infarction (TICI) grade of 2b or 3. The data set was reviewed for time from the stroke to admission, time from admission to puncture, and time from admission to revascularization. Procedure time and fluoroscopy time were also calculated. Clinical outcomes of interest included the hospital length of stay, mortality, NIHSS score, and the mRS score (poor outcome defined as an mRS score > 2) at the last follow-up.

**Statistical Analysis**

IBM SPSS version 27 (IBM Corp.) was used for all analyses. Statistical significance was set at $p < 0.05$. Frequencies and descriptive statistics were used to describe the study population. Means were reported with standard deviations (SDs). Univariate analysis was conducted to compare demographic characteristics, preexisting conditions, clinical presentation, treatment characteristics, and outcomes for Black and White patients. Nonparametric tests were used for the univariate analysis. The interval data did not meet the assumptions of normality per Shapiro-Wilk and Q-Q plots. A multivariate analysis was conducted to study the independent relationship between patient race and mortality. Covariates in the mortality model were selected on the basis of clinical suspicion and significance in univariate analysis. A multilevel (hierarchical) binary logistic regression model was employed to adjust for confounders and identify meaningful effect modifiers on the causative pathway between race and stroke outcomes. Here, “confounder” was defined as a factor associated with both the exposure and outcome that does not lie on the causative pathway. By contrast, a variable defined as an effect modifier does lie on the causative pathway and deserves attention.

**Results**

**Description of Cohort**

Of 565 patients who underwent a mechanical thrombectomy during the study period, race was recorded for 525, with 401 patients identified as either Black or White; 28 were Black (7.0%) and 373 were White (93.0%). The mean age was 68.3 years (SD 13.5 years), and 233 (58.1%) of these patients were men. The mean NIHSS score was 15.2 (SD 7.5) at admission, and 176 patients (43.9%) received intravenous alteplase. The majority of patients had successful revascularization with TICI grades of 2b or 3 (n = 340, 84.8%), and the mean door-to-puncture time was 50.5 minutes (SD 49.6 minutes). Hemicraniectomy was required in 12 patients (3.0%). The rate of hemorrhagic conversion with symptomatic intracerebral hemorrhage was 1.7% (7 of 401 patients).

The mean follow-up time was 117 days (SD 309 days). At follow-up, 278 patients (69.3%) had mRS scores $> 2$ and 63 patients (15.7%) had died. A comparison of the demographic characteristics, preexisting conditions, clinical presentation, treatment characteristics, and outcomes of Black patients and White patients is reported in Tables 1–3.

**Demographics and Preexisting Conditions**

White patients had a higher mean age (68.9 years [SD 13.2 years]) compared with Black patients (61.1 years [SD 13.5 years]) ($p = 0.01$). Smoking was more prevalent among Black patients than White patients (12 [42.9%] vs 90 [24.1%], $p = 0.03$); however, there were no other statistically significant differences between racial groups with respect to sex, BMI, prior stroke, current use of antiplatelets or anticoagulants, insurance status, coronary artery disease, diabetes, hypertension, or hyperlipidemia ($p > 0.05$ for all).

**Clinical Presentation and Treatment Characteristics**

The average NIHSS score at admission was similar between the two racial groups. However, the mean time from stroke onset to hospital presentation was significantly greater for Black patients (604.6 minutes) than White patients (333.4 minutes) ($p = 0.007$). At our institution, the mean time from presentation to revascularization was shorter for Black patients (66.8 minutes) than White patients (93.5 minutes) ($p = 0.04$). Total procedural time was significantly shorter for Black patients (27 minutes) than for White patients (43 minutes) ($p = 0.002$). There were no statistically significant differences in fluoroscopy time, procedural success (TICI grade 2b or 3), hospital length...
### TABLE 1. Comparison of demographic characteristics and preexisting conditions

| Variable                      | All Patients (n = 401) | Black Patients (n = 28) | White Patients (n = 373) | p Value |
|-------------------------------|------------------------|-------------------------|--------------------------|---------|
| Mean age, yrs (SD)            | 68.3 (13.5)            | 61.1 (15.4)             | 68.9 (13.2)              | 0.01    |
| Male sex                      | 233 (58.1)             | 21 (75.0)               | 212 (56.8)               | 0.06    |

**Notes:**
- ACA = anterior cerebral artery; ICA = internal carotid artery; IV tPA = intravenous tissue plasminogen activator; MCA = middle cerebral artery; sICH = symptomatic intracerebral hemorrhage.
- * Unable to calculate p value due to insufficient sample size for comparative groups.
of stay, or rate of hemicraniectomy (Tables 2 and 3; \( p > 0.05 \) for all).

Clinical Outcomes

At follow-up, Black patients had a higher risk of mortality following mechanical thrombectomy than White patients (9 [32.1\%] vs 54 [14.5\%], \( p = 0.01 \)). The mean NIHSS score was also significantly greater at the last follow-up for Black patients (17.6 [SD 14.5] vs 12.9 [SD 13.9], \( p = 0.02 \)).

Hierarchical Binary Logistic Regression

Hierarchical binary logistic regression analysis was used to analyze the relationship between patient race and stroke mortality. The analysis isolated “time from stroke onset to presentation” as a major effect modifier on the causative pathway between patient race and stroke mortality. Before addition of this effect modifier, Black race was a significant predictor in the binary logistic regression analysis (OR 4.44, 95\% CI 1.37–14.41; \( p = 0.01 \)). After the addition of “time from stroke onset to presentation,” Black race was no longer a predictor of mortality (OR 2.62, 95\% CI 0.74–9.24; \( p = 0.14 \)). Other covariates that were adjusted for included age, sex, smoking status, insurance status, NIHSS score, door-to-puncture time, procedure time, and TICI grade. These covariates were not associated with stroke mortality and did not influence the effect of patient race on stroke mortality (all \( p > 0.25 \)). The hierarchical models with and without “time from stroke onset to presentation” are presented in Table 4.

Discussion

In this single-center comparison of outcomes after mechanical thrombectomy, we found higher rates of mortality and longer times to presentation in Black patients than in White patients. Inequalities in stroke severity and mortality between Black patients and White patients are extensively reported in earlier literature.\(^ {15} \) This inequality was demonstrated in a multivariable analysis that was adjusted for potential confounders in age, sex, insurance status, preexisting conditions, smoking status, NIHSS score at admission, door-to-puncture time, and TICI grade. Furthermore, patients in both racial groups were similar with respect to demographic conditions, preexisting conditions, and presenting stroke severity (NIHSS score). All patients at our institution had comparable rates of successful recanalization, with faster door-to-revascularization times in Black patients. However, recent nationwide studies have demonstrated racial and ethnic disparities in the use of mechanical thrombectomy for stroke.\(^ {1, 26, 29} \) These studies acknowledge that the disparity in use of mechanical thrombectomy

| Variable | All Patients (n = 401) | Black Patients (n = 28) | White Patients (n = 373) | \( p \) Value |
|----------|-----------------------|------------------------|--------------------------|------------|
| Mean length of stay, days (SD) | 8.5 (8.2) | 7.2 (4.9) | 8.6 (8.4) | 0.89 |
| Hemicraniectomy, n (%) | 12 (3.0) | 1 (3.6) | 11 (2.9) | 0.85 |
| Mortality, n (%) | 63 (15.7) | 9 (32.1) | 54 (14.5) | 0.01 |
| mRS score >2, n (%) | 278 (69.3) | 23 (82.1) | 255 (68.4) | 0.13 |

| TICI grade 2b/3 | 1.2 (0.4–3.8) | 1.0 (0.3–3.0) |
may be attributed to preadmission factors, such as delayed time from stroke onset to hospital presentation.

Our results show that the mean time from stroke onset to hospital presentation for Black patients was almost twice that for White patients. Delayed presentations lead to an increased size of the ischemic core and a smaller radius of the salvageable penumbra. This undoubtedly decreases the overall use and efficacy of mechanical thrombectomy; however, the present study did not analyze the size of the ischemic core or the radius of the penumbra. The cause of delayed presentation among Black patients is multifactorial. Earlier literature suggested that delayed presentation may be due to disparities in acute stroke treatment allocation, emergency medical service use, and personal health education, as well as the exclusion of predominantly Black neighborhoods from mainstream resources. Furthermore, in a cohort of patients treated for stroke at a tertiary-care hospital, Springer et al. found that Black patients were less likely than White patients to use emergency medical services and were more likely to have delayed hospital arrival times ($\geq$ 3 hours) after stroke onset. In 2 earlier nationwide analyses, Attenello et al. and Brinjikji et al. both found that Black patients had significantly fewer admissions to hospitals performing mechanical thrombectomy procedures at high volumes. Black patients were more likely than White patients to be admitted to low-resource centers without endovascular capabilities and subsequently transferred to stroke centers. Brinjikji et al. demonstrated that racial group but not insurance status was associated with disparities in access to mechanical thrombectomy. In a population-based study in southern Texas, Smith et al. found that Hispanic patients were less likely than non-Hispanic patients to arrive at stroke centers by emergency medical services. The disparity of thrombectomy access and presentation timing in ethnic groups might be mitigated by institutional solutions, including stroke education targeted to groups associated with disparities and clinics and/or emergency departments in underprivileged areas for more accessible healthcare access.

Despite similar NIHSS scores at hospital admission and discharge, Black patients had significantly higher mean NIHSS scores at long-term follow-up. In earlier literature, it has been reported that Black patients experienced more long-term disability after stroke than White patients. This finding is attributed to multiple factors, including disparities in access to rehabilitation, primary care follow-up, and social support. In the present study, descriptive analysis of effect sizes for several other functional outcomes, including an mRS score $> 2$ at the latest follow-up, also indicated racial disparities. We suspect these clinically important factors represent type II errors, and future studies with larger sample sizes should be conducted.

Limitations

The retrospective and single-center study design inherently limits the generalizability of our results. Black patients were a significant minority, comprising only 7% of the cohort (28 patients). The small sample size weakened our statistical power and is an acknowledged limitation of the study. When interpreting results, we recommend examining effect sizes, frequencies, and means in the context of clinical judgment and experience. We encourage the design of larger multi-institutional studies to analyze this critical healthcare disparity further. Our study did not analyze the size of the ischemic core or the radius of the penumbra. The reasons for delayed presentation in Black patients are unknown and warrant investigation in future studies and quality-improvement efforts.

Conclusions

Compared with White patients, Black patients in our cohort had a higher risk of death following mechanical thrombectomy for stroke. Black patients had nearly twice the average time from stroke symptom onset to hospital presentation. The increased risk appeared to be associated with access-related factors. Hierarchical logistic regression analysis revealed that delayed presentation was a significant effect modifier in the causative pathway between patient race and stroke mortality. Further research and improvements are needed to optimize the social determinants of health among patients who experience stroke.

**Disclosures**

The authors report no conflict of interest concerning the materials or methods used in this study or the findings specified in this paper.

**Author Contributions**

Conception and design: Albuquerque, Catapano, Jadhav, Ducruet. Acquisition of data: Nguyen, Farhadi, Ngo, Rutledge, Rahman, Baranoski. Analysis and interpretation of data: Catapano, Rumalla, Srinivasan. Drafting the article: Catapano, Rumalla. Critically revising the article: Albuquerque, Srinivasan, Rutledge, Rahman, Baranoski, Cole, Jadhav, Ducruet. Reviewed submitted version of manuscript: Albuquerque. Statistical analysis: Catapano, Rumalla, Cole. Study supervision: Albuquerque.
