Abstract

Introduction: Basal cell carcinoma (BCC) is the most common non-melanotic skin cancer. It has variable clinical and histological subtypes that vary in their aggressiveness and liability to recurrence and metastasis. Chronic ultraviolet radiation exposure is considered to be the main risk factor for developing BCC; therefore it typically arises on sun-exposed skin, mainly the head and neck.

Case presentation: We present the case of a 55-year-old male who presented with a lesion on the scrotum for 2 years. The lesion was clinically presumed benign and initially treated with curettage. Microscopic examination revealed an incompletely resected micronodular BCC with sebaceous differentiation. Therefore, a second excisional biopsy was performed to completely excise the incidentally-discovered malignant tumor.

Conclusion: We report the first case of micronodular BCC arising on the scrotum. The goal of our article is to draw clinicians’ attention to the possible involvement of unexposed skin with BCC and we highlight the importance of accurate diagnosis and prompt treatment due the aggressive nature of micronodular BCC.

Introduction

Non-melanotic skin cancer (NMC) is the most common cancer in the world. Basal cell carcinoma (BCC) and squamous cell carcinoma (SCC) represent 99% of all NMCs with BCC being the most prevalent. However, accurate data about their prevalence is scarce, mainly because they are not reported separately in national cancer registries and many cases are not fully tracked due to the successful treatment of the tumor via surgery or ablation [1, 2].

BCC usually arises on chronically photoexposed areas in the elderly; it has been rarely reported to occur on unexposed skin such as the trunk or genitalia.

We report the case of a 55-year old man who presented with a tumor-like lesion on the scrotum for two years. The lesion was excised and subsequently determined to be a micronodular BCC of the scrotum. To the best of our knowledge, this is the first reported case of micronodular BCC occurring on the scrotum.

Case Presentation

A 55-year-old Caucasian man presented to the outpatient clinic with a soft lesion on the left side of the scrotum, present for two years.

On inspection, the lesion appeared as a bluish-black nodule with rolled edges and a smooth surface. It measured 7 mm in diameter and was 4 mm raised above the surrounding skin level (Fig. 1).

According to the patient, the nodule wasn’t painful, but due to its location in an intertriginous area that is liable to continuous friction and moisture, the lesion was prone to recurrent irritation leading to oozing, maceration, and foul odor.

The lesion started as a punctate black macule on the left side of the scrotum. The patient made several failed attempts to remove it with a razor blade over the years.

The rest of the physical examination was unremarkable and no lymphadenopathy was present.

Based on the patient’s history, physical examination, and the location of the lesion, the lesion was suspected to be an angiokeratoma. Consequently, the lesion was removed by shave biopsy and sent for microscopic examination.

Microscopic examination revealed small nests of basaloid cells extending from the epidermis and infiltrating the reticular dermis (Fig. 2-a). Peripheral palisading of the nuclei was minimal and retraction artifact was almost absent.

High-power magnification revealed multiple basaloid cells with large hyperchromatic nuclei numerous mitotic figures. Worthy of notice is the presence of heavy pigmentation within the tumour nests and the melanophages in the surrounding stroma.

Furthermore, multiple foci of sebaceous differentiation were noted within the basaloid nests (Fig. 2-b).

These microscopic findings led to establish the diagnosis of a scrotal pigmented micronodular BCC with sebaceous differentiation.

The deep surgical margin was positive for malignant cells; therefore, the patient underwent a subsequent surgical procedure to completely excise the tumor.

On follow-up, four months later, no signs of recurrence were noted.

Discussion

Basal cell carcinoma is the most frequently occurring cancer in humans. It arises from the basal layer of the epidermis and grows slowly over multiple years.

Key risk factors for developing BCCs have been recognized, such as ultraviolet radiation, fair complexion, chronic arsenic exposure, ionizing radiation, personal or family history for BCC and genetic predisposition [3, 4].

In our case, the patient had no personal or family history of BCC and no prior exposure to ionizing radiation or other carcinogens. The location of the carcinoma on the scrotum in our case renders ultraviolet exposure an unlikely culprit.
Basal cell carcinoma has multiple histological subtypes, and they can be classed according to their risk of recurrence to low-risk and high-risk subtypes. The nodular, superficial, fibroepithelial, pigmented, and infundibulocystic BCC are classified as low-risk subtypes, while the infiltrative, micronodular, morpheaform, basosquamous, and BCC with sarcomatoid differentiation are considered as the higher-risk subtypes [5]. However, histological patterns may overlap.

Nodular BCC is the most common variant, characterized clinically by rolled edges, surface telangiectasia, and a central ulcer, giving rise to what is known as the rodent ulcer.

The micronodular variant is an aggressive type of BCC that is liable to recur and hard to eradicate. It occurs most frequently in the head and neck area [6]. Clinically, micronodular BCC typically presents as a poorly defined infiltrated lesion that rarely ulcerates.

Approximately, 80–85% of BCC occur on the head and neck, while 15% develop on the trunk [7]. According to a classic review conducted by Rabbari and Mehergan, less than 0.5% of BCCs were located in the genital area [8].

We searched the Pubmed database using the Medical Subject Headings (MeSH) Terms: “Carcinoma, Basal cell” AND “scrotum”.

Only 14 cases were reported over the past twenty years; the patients' details, tumor morphology, and microscopic classification are summarized in Table 1.

| Ref | Year | Authors | Country | Patient Age | Morphology | Pigmentation | Size (cm) | Microscopic type | Metastasis | Months to presentation | Carcinogen exposure |

| 19  | 2016 | Delto, et al. | USA | 69 | Fungating verruciform mass, flat lesion | No | 10 | - | No | - | NF, (smoker) |
| 20  | 2016 | Hernandez, et al. | Spain | 50 | Eroded exophytic tumor | No | 1 | Solid BCC | No | 12 | Asbestos |
| 21  | 2018 | Padoveze et al. | Brazil | 87 | Perlaceous tumor with telangiectasias | No | 2.5 | Nodular BCC | No | 6 | No |
| 22  | 2020 | Han et al. | China | 74 | Nodule | No | 2 | Superficial BCC | No | 144 | No |
| 23  | 2021 | Current case | Syria | 55 | Nodule | Yes | 0.7 | Micronodular BCC | No | 24 | No |

The average age of patients was 67.6 years old (49–87 years) and the most commonly reported clinical morphology was the ulcerated nodule with pearly borders. The average age of the lesion at presentation was 6.5 years (3 months-51 years).
Unlike our case, the reported lesions were infrequently pigmented at presentation (4 cases).

There were no reported cases of micronodular BCCs arising from the scrotal dermis, our article is thus the first reported case of such a rare presentation in the literature.

**Conclusion**

The presence of BCC in an unusual anatomical location represents a diagnostic challenge for clinicians. Our report adds to the growing body of literature on the unusual sites of basal cell carcinoma. Although the majority of BCCs occur in sun-exposed areas, a diagnosis of BCC should never be excluded merely due to the absence of sun exposure. Clinicians need to be aware of the variable morphologic features of BCC and its possible occurrence in unusual sites, such as the genital area. Prompt diagnosis and proper treatment of BCC is crucial to spare the patient long-term consequences and preserve appropriate quality of life.

**Abbreviations**

BCC
Basal cell carcinoma

NMC
Non-melanotic skin cancer

SCC
Squamous cell carcinoma

**Declarations**

**Availability of data and materials**

Not applicable.

**Ethics approval and consent to participate**

Not applicable.

**Consent for publication**

Written informed consent was obtained from the patient for publication of this case report and any accompanying images. A copy of the written consent is available for review by the Editor-in-Chief of this journal.

**Competing interests**

The authors declare that they have no competing interests.

**Funding**

This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

**Authors’ contributions**

MY analyzed and interpreted the patient’s data and drafted the manuscript. LK performed the literature review drafted the manuscript. HA and AB supervised the project, reviewed the original draft, and provided critical feedback. All authors have read and approved the final version of the manuscript.

**Acknowledgements**

We would like to express our deep gratitude to our colleagues at the University Hospital of Dermatology and Venereology for providing their valuable expertise and insight.
