We provide the classification of possible wave structures evolving from initially discontinuous profiles for the photon fluid propagating in a normal dispersion fiber. The dynamics of light field is described by the generalized Chen-Lee-Liu equation which belong to a family of the nonlinear Schrödinger equations with self-steepening type term appearing due to retardation of the fiber material response to variations of the electromagnetic signal. This equation is also used in investigations of dynamics of modulated wave propagating through a single nonlinear transmission network. We describe its periodic solutions and the corresponding Whitham modulation equations. The wave patterns generated by the initial parameters profiles are composed of different building blocks which are presented in detail. It is shown that evolution dynamics in this case is much richer than that for the nonlinear Schrödinger equation. Complete classification of possible wave structures is given for all possible jump conditions at the discontinuity. Our analytic results are confirmed by numerical simulations.

Keywords: nonlinear medium, optical fibers, Chen-Lee-Liu equation, dispersive shock waves, solitons, Whitham modulation equations.

1. INTRODUCTION

The evolution of light pulses in waveguides is a subject of active modern experimental and theoretical research. One of the trends in this field is the study of so-called dispersive shock waves. Such structures are observed in various physical media, such as water waves (where such waves are often called undular bores), Bose-Einstein condensates, waves in magnetics, in nonlinear optics and other areas of physics (see, e.g., [1, 2]). It is well known that if one neglects the effects of dissipation and dispersion, then the theory of nonlinear propagation of light envelope suffers from a wave breaking singularity developed at some finite fiber length after which a formal solution of nonlinear wave equations becomes multi-valued and loses its physical meaning. The account of dispersion eliminates such a non-physical behavior. But the evolution equations for the envelopes acquire higher order derivatives, and after the wave breaking moment, instead of the multi-valued region, an expanding region of fast nonlinear oscillations is formed. Envelope parameters in such a structure change slowly compared with the characteristic oscillations frequency and their wavelength. This region of fast oscillations is called “dispersive shock wave” (DSW).

One of the most important problems in which DSWs can occur is the Riemann problem, which includes classification of wave structures resulting from the evolution of the initial discontinuity. This problem has played an important role since the classical paper of B. Riemann [3], subsequently supplemented by the jump conditions of W. Rankin [4] and H. Hugoniot [5, 6], it served as a prototype of the example of shocks formation in dispersionless media with small viscosity. The full classification of possible wave patterns evolving from initial discontinuities was obtained by N. Kotchine [7]. However, in the case of optical systems, we have dispersion instead of viscosity. The problem where DSWs are formed instead of viscous shocks has been studied for the first time in the context of the physics of shallow water waves which evolution is described by the celebrated Korteweg-de Vries (KdV) equation [8, 9]. The equations governing the slow evolution of the envelope of the nonlinear oscillations had been derived by G. B. Whitham [10] and they were applied to the description of the DSW structure by A. V. Gurevich and L. P. Pitaevskii [11]. Because of the universality of the KdV equation, this approach can naturally be applied to many other physical situations. Later it became clear [12] that the diagonalization of the Whitham modulation equations was possible due to the special property discovered in [13] of the complete integrability of the KdV equation. Development of the finite-gap integration method [14, 15], as well as the methods of deriving [12, 16] and solving the Whitham equations [17, 18], made it possible to extend the Gurevich-Pitaevskii approach to a number of other completely integrable equations of physical interest (see, for instance, [2]) and it admit investigation of non-genuinely nonlinear hyperbolic systems.

In nonlinear optics, DSWs were observed long ago (see, e.g., [19, 20]), but they remain the subject of active current experimental (see, e.g., [21–23]) and theoretical (see, e.g., [24, 25]) research. In the fiber optics applications, the dynamics of pulses is usually described by the nonlinear Schrödinger (NLS) equation that accounts for two main effects—quadratic normal dispersion and Kerr nonlinearity. For this case, the theory of DSWs is already well developed and the main parameters of the arising wave structures can be calculated for typical idealized situations in simple analytical form. Extension of the
Gurevich-Pitaevskii approach to the NLS equation became possible only after derivation of the Whitham modulation equations \[26\] by the methods based on the inverse scattering transform for the NLS equation \[28\] which means its complete integrability. In particular, consideration of many realistic problems can be reduced to analysis of the so-called Riemann problem of evolution of discontinuity in the initial data. Such a discontinuity can appear, for example, as a jump in the time dependence of the light intensity, which is mostly typical in physics of light pulses in fibers, or evolve from a “collision” of two pulses in which case not only intensity has a discontinuity but also the time and space derivatives of the phase. Classification of possible wave structures in the NLS equation theory was given in Refs. \[29\] \[30\] and it provides the theoretical basis for calculation of characteristic parameters of such experiments as that of Ref. \[31\]. It was shown that the NLS theory evolution of any initial discontinuity leads to a wave pattern consisting of a sequence of building blocks two of which are represented by either the rarefaction wave or the DSW. However, in nonlinear optics, besides quadratic dispersion and Kerr nonlinearity, many other effects can play important role in propagation of pulses. For instance, in experiment \[32\] with photorefractive material the saturation of nonlinearity is quite essential and the corresponding theory of DSWs was developed in Ref. \[33\]. Naturally, in order to get a better understanding of the higher-order nonlinear effects, it is necessary to introduce several other higher-order terms, such as third-order dispersion, quintic nonlinear terms, etc, into the Hirota equation \[34\], Kundu-Eackhuas equation \[35\] \[36\], and a generalized NLS equation \[38\]. Due to recent technological developments in laser and ultra-high-bit-rate optical fiber communication, these higher-order nonlinear effects are unavoidable in many optical systems when modeling the transmission of ultra-short and high intense light pulses in nonlinear optical media. In fiber optics, one needs to take into account such effects as dissipation, higher-order dispersion, intra-pulse Raman scattering and self-steepening (see, e.g., \[49\]). These effects can drastically change evolution of DSWs leading sometimes to violation of the supposition that such an evolution is adiabatically slow, as apparently it happens in the case of considerable higher order dispersion \[10\]. Theoretically, the self-steepening term that arise in optical setting is commonly associated with the class of the derivative nonlinear Schrödinger (DNLS) equation. It is relevant to mention that the self-steepening of an optical fiber pulse, otherwise called Kerr dispersion, arises when the group velocity of a pulse depends on the intensity \[41\]. Several versions of the DNLS equations have been studied from different points of view. Well known NLS equations with derivative terms include the Kaup-Newell equation \[42\], the Chen-Lee-Liu equation \[43\], and the Gerjikov-Ivanov equation \[44\] which arise in theories of nonlinear optics, fluid dynamics and plasma physics. These nonlinear wave equations are usually called DNLS-I, DNLS-II and DNLS-III equations, respectively. The pulse propagation in a single-mode optical fiber can be described by the Chen-Lee-Liu (CLL) equation

\[
iq_t + \frac{1}{2} q_{xx} + i|q|^2 q_x = 0, 
\]

where the coordinates \(t\) and \(x\) denote propagation distance and retarded time, but represent slow time and spatial coordinate traveling with group velocity in hydrodynamics, respectively. In optical fiber setting, the term involving parameter \(\delta > 0\) is usually associated with the self-steepening phenomena \[45\]. In Ref. \[46\] J. Moses et al. performed optical pulse propagation involving self-steepening without self-phase-modulation. This experiment provides the first experimental evidence of the CLL equation. The CLL equation \[1\] corresponds to a situation where the dispersionless Riemann invariants depend non-monotonously on the physical variables, that is, the problem is not-genuinely nonlinear (see, e.g., \[47\]). In this case, new types of waves structures arise, which are similar to contact discontinuities in the theory of viscous shock waves. So the CLL equation can be considered as an example of non-convex dispersive hydrodynamics.

We consider the propagation of an optical pulse inside a monomode fiber modeled by a generalized Chen-Lee-Liu (generalized CLL) equation

\[
iq_t + \frac{1}{2} q_{xx} - |q|^2 q + i\delta|q|^2 q_x = 0, 
\]

that also includes the Kerr nonlinearity, which is inevitable at sufficiently high intensities. The generalized CLL equation is simply related to the CLL equation (see, e.g., \[48\]). This equation is also used in the investigation of modulated wave dynamics of waves propagating through a single nonlinear transmission network which also presents practical interest (see \[49\] and references therein).

Motivated by applications of the generalized CLL equation \[2\] we consider the method which permits one to predict a wave pattern arising from any given data for an initial discontinuity. The method is quite general and it was applied to the generalized NLS equations with self-steepening nonlinearity \[50\] \[51\] and to the Landau-Lifshitz equation for magnetics with easy-plane anisotropy \[52\]. Here we extend the theory to not-genuinely case of the generalized CLL equation \[2\]. The exact integrability of this equation makes it possible to develop Whitham modulational theory for describing configurations where nonlinear waves are slowly modulated, as observed in dispersive shocks.

The paper is organized as follows: the influence of the last term of the generalized CLL equation \[2\] on the dynamics of linear waves that propagate along a uniform background and small-amplitude limit are discussed in Sec. \[2\]. The exact integrability of this equation is used in Sec. \[3\] for derivation of the Whitham modulational equations. In Sec. \[4\] we describe the elementary wave...
structures that appear as building blocks in the general wave patterns. The full classification of the solutions of the Riemann problem is presented in Sec. 5. The last Sec. 6 is devoted to conclusions.

2. LINEAR WAVES AND SMALL DISPERSION AND WEAK NONLINEARITY LIMITS

Let us turn to study of linear waves and the small-amplitude and weak dispersion limits when these effects are taken into account in the main approximation. That is, we are interested in propagation of disturbances along a uniform background intensity \( \rho_0 \). To this end, it is convenient to use the physical variables of intensity \( \rho(x,t) \) and chirp \( u(x,t) \). To go to the equations for these variables, we apply the Madelung transform

\[
q(x,t) = \sqrt{\rho(x,t)} \exp \left( i \int u(x',t)dx' \right). \tag{3}
\]

After its substitution into Eq. (2), separation of the real and imaginary parts and differentiation of one of the equations with respect to \( x \), we get the system

\[
\begin{align*}
\rho_t + (\rho u + \frac{1}{2} \delta \rho^2)_x = 0, \\
u_t + uu_x + \rho_x + \delta (pu)_x + \left( \frac{\rho_x^2}{8 \rho^2} - \frac{\rho_{xx}}{4 \rho} \right)_x = 0. \tag{4}
\end{align*}
\]

The last term on the left-hand side of the second equation describes the dispersion.

The linear dispersion relation of the system (4) for linear waves propagating along a constant background \( \rho_0 \) has the form

\[
\omega_{1,2}(k) = \left( \delta \rho_0 \pm \sqrt{\frac{k^2}{4} + \rho_0} \right) k. \tag{5}
\]

Here \( \omega \) is the frequency of the linear waves and \( k \) is the wave number. Suppose that at the initial moment the phase of the wave is constant and there is only the intensity perturbation. After standard calculations we get the solution of linear problem expressed in terms of the Fourier transform \( \tilde{\rho}_0'(k) \) of the initial (input) intensity linear disturbance

\[
\rho'(x,t) = \frac{1}{4\pi} \int_{-\infty}^{+\infty} \tilde{\rho}_0'(k) \left[ e^{i(kx-\omega t)} + e^{i(kx-\omega t)} \right] dk, \tag{6}
\]

One can see that an initial pulse splits into two smaller pulses, however, on the contrary to the NLS case, two pulses propagate with different group velocities. This is manifestation of lack of the \( x \) inversion invariance, which is caused by the last term in the generalized CLL equation (4).

We are interested in the leading dispersion and nonlinear corrections to the dispersionless linear propagation of disturbances. Using the system (4) and applying the standard perturbation theory for the amplitude of the perturbation and for the weak dispersion (see, for example, [1]), one can obtain a small-amplitude analog of Eq. (2). Let the wave propagate in the positive direction of the \( x \)-axis. Then an approximate equation for \( \rho' = \rho - \rho_0 \) takes the form

\[
\frac{\partial \rho'}{\partial t} + (\delta \rho_0 + \sqrt{\rho_0}) \frac{\partial \rho'}{\partial x} + \frac{3}{2} \frac{1 + \delta \sqrt{\rho_0}}{\sqrt{\rho_0}} \frac{\partial \rho'}{\partial x} \frac{\partial \rho'}{\partial x} - \frac{1}{8 \sqrt{\rho_0}} \frac{\partial^3 \rho'}{\partial x^3} = 0. \tag{7}
\]

This is the Korteweg-de Vries (KdV) equation. Formation of DSWs from initial discontinuities in the KdV equation theory has been well known since the pioneering paper Ref. [11] — the initial discontinuity evolves into either rarefaction wave or cnoidal DSW. Similarly for another simple wave propagating in the negative direction of the \( x \)-axis we have the Gardner equation

\[
\frac{\partial \rho'}{\partial t} + (\delta \rho_0 - \sqrt{\rho_0}) \frac{\partial \rho'}{\partial x} + \frac{3}{2} \frac{1 - \delta \sqrt{\rho_0}}{\sqrt{\rho_0}} \frac{\partial \rho'}{\partial x} \frac{\partial \rho'}{\partial x} + \frac{1}{8 \sqrt{\rho_0}} \frac{\partial^3 \rho'}{\partial x^3} = 0. \tag{8}
\]

In the limit \( \delta \sqrt{\rho} \to 1 \) the last equation reduces to the modified Korteweg-de Vries (mKdV) equation

\[
\frac{\partial \rho'}{\partial t} + \frac{3}{4 \rho_0^{3/2}} \rho_x^2 \frac{\partial \rho'}{\partial x} + \frac{1}{8 \sqrt{\rho_0}} \frac{\partial^3 \rho'}{\partial x^3} = 0. \tag{9}
\]

Situation for the mKdV and Gardner equations is much more complicated than for the KdV case and in this case we can get eight different structures including, besides the rarefaction waves and cnoidal DSWs, also trigonometric DSWs, combined shocks and their combinations separated by plateau. Therefore one should expect that in the case of Riemann problem for Eq. (2) we also have to get much richer structure than in the NLS case. To solve this problem, at first we have to find periodic solutions of Eq. (2) in convenient form, that is in the form parameterized by the parameters related with the Riemann invariants of the corresponding Whitham modulation equations by simple formulas. In the next section we shall obtain the periodic solutions by this method and derive the Whitham equations.

3. PERIODIC SOLUTIONS AND WHITHAM MODULATION EQUATIONS

The finite-gap integration method (see, e.g., [1]) is based on possibility of representing the generalized CLL equation (2) as a compatibility condition of two systems
of linear equations with a spectral parameter $\lambda$

$$\begin{align*}
\frac{\partial}{\partial x}\left(\psi_1\right) &= \left(\begin{array}{cc}
F & G \\
H & -F
\end{array}\right) \left(\begin{array}{c}
\psi_1 \\
\psi_2
\end{array}\right), \\
\frac{\partial}{\partial t}\left(\psi_1\right) &= \left(\begin{array}{cc}
A & B \\
C & -A
\end{array}\right) \left(\begin{array}{c}
\psi_1 \\
\psi_2
\end{array}\right),
\end{align*}$$

where

$$\begin{align*}
F &= -\frac{i}{2\delta} (\lambda^2 - \delta^2|q|^2 + 1), \\
G &= -gq, \\
H &= q^*\lambda, \\
A &= -\frac{i}{4\delta^2} (\lambda^2 - \delta^2|q|^2 + 1)^2 - \frac{\delta^2}{4} (q_xq^* - q^*q_x) - \frac{i}{2}|q|^2, \\
B &= -\frac{1}{2\delta} (\lambda^2 - \delta^2|q|^2 + 1)q\lambda - \frac{i}{2}q_x\lambda, \\
C &= \frac{1}{2\delta} (\lambda^2 - \delta^2|q|^2 + 1)q^*\lambda - \frac{i}{2}q^*\lambda.
\end{align*}$$

This Lax pair can be obtained by simple transformation from the known Lax pair for the CLL equation [11] (see Ref. [55]). The $2 \times 2$ linear problems [10] and [11] have two linearly independent basis solutions which we denote as $(\psi_1, \psi_2)^T$ and $(\varphi_1, \varphi_2)^T$. We define the “squared basis functions”

$$f = -\frac{i}{2}(\psi_1\varphi_2 + \psi_2\varphi_1), \quad g = \psi_1\varphi_1, \quad h = -\psi_2\varphi_2,$$

which obey the linear equations

$$\begin{align*}
f_x &= iGh - iHg, \\
g_x &= 2Fg + 2iGf, \\
h_x &= -2Fh - 2iHf,
\end{align*}$$

and

$$\begin{align*}
f_t &= iBh - iCg, \\
g_t &= 2Ag + 2iBf, \\
h_t &= -2Ah - 2iCf.
\end{align*}$$

We look for the solutions of these equations in the form

$$\begin{align*}
f &= (\lambda^2 - \delta^2|q|^2 + 1)^2 - f_1 (\lambda^2 - \delta^2|q|^2 + 1) + f_2, \\
g &= -2\delta (\lambda^2 - \delta^2|q|^2 + 1 - \mu) q\lambda, \\
h &= 2\delta (\lambda^2 - \delta^2|q|^2 + 1 - \mu^*) q^*\lambda.
\end{align*}$$

Here the functions $f_1(x,t), f_2(x,t), \mu(x,t)$ and $\mu^*(x,t)$ are unknown; $\mu(x,t)$ and $\mu^*(x,t)$ are not interrelated a priori, but we shall find soon that they are complex conjugate, whence the notation.

Substitution of Eqs. [10] into Eqs. [14] gives after equating the coefficients of like powers of $\lambda$ expressions for the $x$-derivatives of $f_1$ and $f_2$

$$\begin{align*}
f_{1,x} &= 0, \\
f_{2,x} &= \delta^2 (2 - 2\delta^2|q|^2 - f_1) (|q|^2)_x, \quad (17)
\end{align*}$$

and of $|q|^2$ and $\mu$

$$\begin{align*}
(|q|^2)_x &= \frac{i}{\delta} (\mu - \mu^*) |q|^2, \\
(\mu q)_x &= -i\delta (\mu - \mu^*) |q|^2 - \frac{i}{\delta} 2q. 
\end{align*}$$

In a similar way, substitution of [10] into [15] with account of [17] gives equations for the $t$-derivatives of $f_1$ and $f_2$

$$\begin{align*}
f_{1,t} &= 0, \\
f_{2,t} &= \frac{f_1}{2\delta} f_{2,x}. \quad (19)
\end{align*}$$

and

$$\begin{align*}
(|q|^2)_t &= \frac{f_1}{2\delta} (|q|^2)_x. \quad (20)
\end{align*}$$

It is easy to check that the expression $f^2 - gh = P(\lambda)$ does not depend on $x$ and $t$, however it can depend on the spectral parameter $\lambda$. We are interested in the one-phase periodic solution. It is distinguished by the condition that $P(\lambda)$ is an eighth degree polynomial of the form

$$f^2 - gh = P(\lambda) = \prod_{i=1}^4 (\lambda^2 - \lambda_i^2)$$

Equating the coefficients of like powers of $\lambda$ at two sides of this identity, we get

$$\begin{align*}
s_1 &= 2f_1 - 4, \\
s_2 &= f_1^2 + 2f_2 - 4\delta^2|q|^2 (\mu + \mu^*) + 2 [3f_1 - 3 - \delta^2|q|^2] [\delta^2|q|^2 - 1], \\
s_3 &= (s_2 + f_1^2 + 2f_2 + 2 [\delta^4|q|^4 - 1]) [\delta^2|q|^2 - 1] + 2f_1f_2 - 4\delta^2|q|^2 \mu \mu^*, \\
s_4 &= ([f_1 + \delta^2|q|^2 - 1] [\delta^2|q|^2 - 1] + f_2^2). 
\end{align*}$$

Here $s_i$ are standard symmetric functions of the four zeros $\lambda_i^2$ of the polynomial $P(\lambda)$

$$\begin{align*}
s_1 &= \sum_i \lambda_i^2, \\
s_2 &= \sum_{i<j} \lambda_i^2 \lambda_j^2, \\
s_3 &= \sum_{i<j<k} \lambda_i^2 \lambda_j^2 \lambda_k^2, \\
s_4 &= \lambda_1^2 \lambda_2^2 \lambda_3^2 \lambda_4^2. 
\end{align*}$$

Eqs. [22] allow us to express $\mu, \mu^*$ as functions of $|q|^2$.

The last Eq. [22d] gives

$$\begin{align*}
f_1 &= \frac{s_1}{2} + 2, \\
f_2 &= 1 - \delta^4|q|^4 - \frac{s_4}{2} (\delta^2|q|^2 - 1) + \sqrt{s_4}. 
\end{align*}$$

We substitute that into [22b] and [22c] and obtain the system for $\mu$ and $\mu^*$, which can be easily solved to give

$$\begin{align*}
\mu &= \frac{1}{8\delta^2|q|^2} \left[ \left( \frac{s_1}{4} \right)^2 + \frac{1}{2} \delta^2|q|^2 (s_1 + 4 - 2\delta^2|q|^2) \right], \\
\frac{s_4}{4} + \frac{1}{2} \sqrt{s_4} - i \sqrt{-R (\delta^2|q|^2)}.
\end{align*}$$

where
\[ R(\nu) = \nu^4 + s_1 \nu^3 + \left( \frac{3 s_1^2}{8} - s_2^2 + 3 \sqrt{3} s_1 \right) \nu^2 + \left( \frac{1}{16} s_1^2 + s_3 - \frac{1}{4} s_1 s_2 + \frac{1}{2} s_4 \sqrt{\nu} \right) \nu + \left( \frac{1}{4} s_1^2 - s_2 - \frac{1}{2} \sqrt{s_4} \right)^2. \] (26)

The introduced here function \( R \) is a fourth-degree polynomial in \( \nu \) and it is called an algebraic resolvent of the polynomial \( P(\lambda) \), because zeros of \( R(\nu) \) are related to zeros of \( P(\lambda) \) by the following simple symmetric expressions: the upper sign in (26) corresponds to the zeros
\[
\begin{align*}
\nu_1 & = \frac{1}{4} (-\lambda_1 + \lambda_2 + \lambda_3 - \lambda_4)^2, \\
\nu_2 & = \frac{1}{4} (\lambda_1 - \lambda_2 + \lambda_3 - \lambda_4)^2, \\
\nu_3 & = \frac{1}{4} (\lambda_1 + \lambda_2 - \lambda_3 - \lambda_4)^2, \\
\nu_4 & = \frac{1}{4} (\lambda_1 + \lambda_2 + \lambda_3 + \lambda_4)^2.
\end{align*}
\] (27)

and the lower sign in equation (26) corresponds to the zeros
\[
\begin{align*}
\nu_1 & = \frac{1}{4} (-\lambda_1 + \lambda_2 + \lambda_3 + \lambda_4)^2, \\
\nu_2 & = \frac{1}{4} (\lambda_1 - \lambda_2 + \lambda_3 + \lambda_4)^2, \\
\nu_3 & = \frac{1}{4} (\lambda_1 + \lambda_2 - \lambda_3 + \lambda_4)^2, \\
\nu_4 & = \frac{1}{4} (\lambda_1 + \lambda_2 + \lambda_3 - \lambda_4)^2,
\end{align*}
\] (28)

This can be proved by a simple check of the Vieté formulas.

As follows from the second Eqs. (19), the first Eq. (24) gives the expression for the constant phase velocity
\[
V = -\frac{f_1}{2\delta} = -\frac{1}{\delta} \frac{s_1}{4\delta}
= -\frac{1}{\delta} - \frac{1}{4\delta} \sum_{i=1}^{4} \lambda_i^2 = -\frac{1}{\delta} - \frac{1}{4\delta} \sum_{i=1}^{4} \nu_i,
\] (29)

and we find that \( f_2 \) depends on \( \xi = x - Vt \) only. Then from Eq. (20) we see that the intensity \( \rho = |q|^2 \) also depends only on \( \xi \). The equations for dynamics of \( \rho \) can be easily found by substitution of (25) into the first Eq. (18), so we get
\[
\frac{d(\delta^2 \rho)}{d\xi} = \frac{1}{\delta} \sqrt{-R(\delta^2 \rho)},
\] (30)

where \( R \) is, as we know, a fourth degree polynomial with the zeros given in terms of \( \lambda_1 \) by the formulas (27) or (28). This equation can be solved in standard way in terms of elliptic functions. Without going to much detail we shall present here the main results.

We shall assume that \( \lambda_1 \) are ordered according to \( 0 \leq \lambda_1 \leq \lambda_2 \leq \lambda_3 \leq \lambda_4 \) and then both our definitions (27) and (28) give the same ordering of \( \nu_i \); \( \nu_1 \leq \nu_2 \leq \nu_3 \leq \nu_4 \). The real solutions correspond to oscillations of \( \delta^2 \rho \) within the intervals where \( -R(\delta^2 \rho) \geq 0 \).

(A) At first we shall consider the periodic solution corresponding to oscillations of \( \delta^2 \rho \) in the interval
\[
\nu_1 \leq \delta^2 \rho \leq \nu_2.
\] (31)

Standard calculation yields, after some algebra, the solution in terms of Jacobi elliptic functions:
\[
\delta^2 \rho = \nu_2 - \frac{(\nu_2 - \nu_1) \mathrm{cn}^2(\theta, m)}{1 + \frac{\nu_2 - \nu_1}{\nu_2 - \nu_3} \mathrm{sn}^2(\theta, m)},
\] (32)

where it is assumed that \( \delta^2 \rho(0) = \nu_1 \).

\[ \theta = \sqrt{(\nu_3 - \nu_4)(\nu_4 - \nu_2)} \xi/(2\delta), \] (33)

\[ m = \frac{(\nu_4 - \nu_3)(\nu_3 - \nu_1)}{\nu_4 - \nu_2}(\nu_3 - \nu_1), \] (34)

functions \( cn \) and \( sn \) being Jacobi elliptic functions [56].

The period of oscillations along \( x \) axis is equal to function (32)
\[
L = \frac{4K(m)}{\sqrt{(\nu_3 - \nu_4)(\nu_4 - \nu_2)}} = \frac{4K(m)}{\sqrt{(\lambda_3^2 - \lambda_4^2)(\lambda_4^2 - \lambda_2^2)}},
\] (35)

where \( K(m) \) is the complete elliptic integral of the first kind [59].

In the limit \( \nu_3 \to \nu_2 \) \( (m \to 1) \) the period tends to infinity and the solution (32) acquires the soliton form
\[
\delta^2 \rho = \nu_2 - \frac{\nu_2 - \nu_1}{\cosh^2 \theta + \frac{\nu_2 - \nu_1}{\nu_3 - \nu_2} \sinh^2 \theta}.
\] (36)

This is a “dark soliton” for the variable \( \rho \).

The limit \( m \to 0 \) can be reached in two ways.

(i) If \( \nu_2 \to \nu_1 \), then the solution transforms into a linear harmonic wave
\[
\delta^2 \rho \cong \nu_2 - \frac{1}{2}(\nu_2 - \nu_1) \cos(\omega \xi/\delta),
\]

\[ \omega = \sqrt{(\nu_3 - \nu_4)(\nu_4 - \nu_1)}. \] (37)

(ii) If \( \nu_4 = \nu_3 \) but \( \nu_1 \neq \nu_2 \), then we arrive at the nonlinear trigonometric solution:
\[
\delta^2 \rho = \nu_2 - \frac{(\nu_2 - \nu_1) \cos^2 \theta}{1 + \frac{2\nu_2 - \nu_1}{\nu_3 - \nu_2} \sin^2 \theta}.
\]

\[ \theta = \sqrt{(\nu_3 - \nu_4)(\nu_3 - \nu_2)} \xi/(2\delta). \] (38)

If we take the limit \( \nu_2 - \nu_1 \ll \nu_3 - \nu_1 \) in this solution, then we return to the small-amplitude limit (37)
\( \nu_4 = \nu_3 \). On the other hand, if we take here the limit \( \nu_2 \to \nu_3 = \nu_4 \), then the argument of the trigonometric functions becomes small and we can approximate them by the first terms of their series expansions. This corresponds to an algebraic soliton of the form

\[
\delta^2 \rho = \nu_2 - \frac{\nu_2 - \nu_1}{1 + (\nu_2 - \nu_1)^2 \xi^2 / (4\delta^2)}.
\]

(39)

(B) In the second case, the variable \( \delta^2 \rho \) oscillates in the interval \( \nu_3 \leq \delta^2 \rho \leq \nu_4 \).

Here again, a standard calculation yields

\[
\delta^2 \rho = \nu_3 + \frac{(\nu_4 - \nu_3) \cos^2(\theta, m)}{1 + \nu_4 - \nu_3 \sin^2(\theta, m)}.
\]

(41)

with the same definitions \( \nu_3, \nu_4 \), and \( \nu_3 \) for \( \theta, m \), and \( T \), correspondingly. In this case we have \( \delta^2 \rho(0) = \nu_4 \).

In the soliton limit \( \nu_3 \to \nu_2 \) \( (m \to 1) \) we get

\[
\delta^2 \rho = \nu_2 + \frac{\nu_4 - \nu_2}{\cos^2 \theta + \nu_4 - \nu_2 \sin^2 \theta}.
\]

(42)

This is a “bright soliton” for the variable \( \rho \).

Again, the limit \( m \to 0 \) can be reached in two ways.

(i) If \( \nu_4 \to \nu_3 \), then we obtain a small-amplitude harmonic wave

\[
\delta^2 \rho \equiv \nu_3 + \frac{1}{2} (\nu_4 - \nu_3) \cos(\omega \xi / \delta),
\]

(43)

\( \omega = \sqrt{\nu_3 - \nu_1} / (\nu_3 - \nu_2) \).

(ii) If \( \nu_2 = \nu_1 \), then we obtain another nonlinear trigonometric solution,

\[
\delta^2 \rho = \nu_3 + \frac{(\nu_4 - \nu_3) \cos^2 \theta}{1 + \nu_4 - \nu_3 \sin^2 \theta},
\]

\( \theta = \sqrt{\nu_3 - \nu_1} / (\nu_3 - \nu_2) \).

(44)

If we assume that \( \nu_4 - \nu_3 \ll \nu_2 - \nu_1 \), then this reproduces the small-amplitude limit \( \delta^2 \rho \) with \( \nu_2 = \nu_1 \). On the other hand, in the limit \( \nu_3 \to \nu_2 \) \( \nu_2 = \nu_1 \) we obtain the algebraic soliton solution:

\[
\delta^2 \rho = \nu_1 + \frac{\nu_4 - \nu_1}{1 + (\nu_4 - \nu_1)^2 \xi^2 / (4\delta^2)}.
\]

(45)

The convenience of this form of periodic solutions of our equation is related with the fact that the parameters \( \lambda_i \), connected with \( \nu_i \) by the formulas \( \lambda_1, \lambda_2, \lambda_3 \), play the role of Riemann invariants in Whitham theory of modulations. For both cases \( \lambda_1, \lambda_2, \lambda_3 \) we have the identities

\[
m = \frac{(\nu_4 - \nu_3)(\nu_2 - \nu_1)}{(\nu_4 - \nu_3)(\nu_3 - \nu_1)} = \frac{(\lambda_1^2 - \lambda_2^2)(\lambda_2^2 - \lambda_1^2)}{(\lambda_3^2 - \lambda_2^2)(\lambda_3^2 - \lambda_1^2)}.
\]

(46)

Now we shall consider slowly modulated waves. In this case, the parameters \( \lambda_i \) \( (i = 1, 2, 3, 4) \) become slowly varying functions of \( x \) and \( t \) changing little in one period and they can serve as Riemann invariants. Evolution of \( \lambda_i \) is governed by the Whitham modulation equations

\[
\frac{\partial \lambda_i}{\partial t} + v_i \frac{\partial \lambda_i}{\partial x} = 0, \quad i = 1, 2, 3, 4.
\]

(47)

The Whitham velocities appearing in these equations can be computed by means of the formula

\[
v_i = \left( 1 - \frac{L}{\partial \lambda_i} \right) V_i, \quad \text{where} \quad \partial_i = \partial / \partial \lambda_i.
\]

(48)

with the use of Eqs. \( \lambda_1, \lambda_2, \lambda_3 \). Hence, a simple calculation yields the explicit expressions

\[
v_1 = -\frac{1}{\delta} + \frac{1}{4\delta} \sum_{i=1}^{4} \lambda_i^2 - \frac{1}{2\delta} (\lambda_1^2 - \lambda_2^2) K(m),
\]

\[
v_2 = \frac{1}{\delta} + \frac{1}{4\delta} \sum_{i=1}^{4} \lambda_i^2 + \frac{1}{2\delta} (\lambda_1^2 - \lambda_2^2) K(m),
\]

\[
v_3 = \frac{1}{\delta} + \frac{1}{4\delta} \sum_{i=1}^{4} \lambda_i^2 - \frac{1}{2\delta} (\lambda_1^2 - \lambda_2^2) K(m),
\]

\[
v_4 = \frac{1}{\delta} + \frac{1}{4\delta} \sum_{i=1}^{4} \lambda_i^2 + \frac{1}{2\delta} (\lambda_1^2 - \lambda_2^2) K(m).
\]

(49)

In a modulated wave representing a dispersive shock wave, the Riemann invariants change with \( x \) and \( t \). The dispersive shock wave occupies a space interval at which edges two of the Riemann invariants coincide. The soliton edge corresponds to \( \lambda_1 = \lambda_2 \) \( (m = 1) \) and at this edge the Whitham velocities are given by

\[
v_1 = -\frac{1}{\delta} + \frac{1}{4\delta} (3\lambda_1^2 + \lambda_2^2),
\]

\[
v_2 = v_3 = -\frac{1}{\delta} + \frac{1}{4\delta} (\lambda_1^2 + 2\lambda_2^2 + \lambda_3^2),
\]

\[
v_4 = -\frac{1}{\delta} + \frac{1}{4\delta} (\lambda_1^2 + 3\lambda_2^2).
\]

(50)

The small amplitude limit \( m \to 0 \) can be obtained in two ways. If \( \lambda_3 = \lambda_4 \), then we get

\[
v_1 = -\frac{1}{\delta} + \frac{1}{4\delta} (3\lambda_1^2 + \lambda_3^2),
\]

\[
v_2 = v_3 = -\frac{1}{\delta} + \frac{1}{4\delta} (\lambda_1^2 + 3\lambda_3^2),
\]

\[
v_4 = -\frac{1}{\delta} + \frac{1}{4\delta} (\lambda_1^2 - \lambda_3^2)^2
\]

(51)

and if \( \lambda_2 = \lambda_1 \), then

\[
v_1 = v_2 = -\frac{1}{\delta} + \frac{1}{4\delta} (3\lambda_1^2 + \lambda_2^2),
\]

\[
v_3 = -\frac{1}{\delta} + \frac{1}{4\delta} (3\lambda_3^2 + \lambda_2^2),
\]

\[
v_4 = -\frac{1}{\delta} + \frac{1}{4\delta} (\lambda_3^2 + 3\lambda_2^2).
\]

(52)

We can now proceed to the description of key elements (“building blocks”) from which the wave patterns are constructed.
4. KEY ELEMENTS

We consider in the present paper the so-called Riemann problem. This corresponds to the study of the evolution of initial discontinuous profiles of the form
\[
\rho(t=0) = \begin{cases} 
\rho^L, & x < 0, \\
\rho^R, & x > 0, 
\end{cases} \\
u(t=0) = \begin{cases} 
u^L, & x < 0, \\
u^R, & x > 0. 
\end{cases}
\] (53)

Evolution of such a pulse leads to formation of quite complex structures consisting of simpler elements. We shall describe these elements in the present section.

4.1. Rarefaction waves

For smooth enough wave patterns we can neglect the last dispersion term in the second equation of the system [4] and arrive at the so-called dispersionless equations
\[
\rho_t + (\rho u + \frac{1}{2} \delta \rho^2) x = 0, \\
u_t + uu_x + \rho x + \delta (\rho u)_x = 0. 
\] (54)

First of all, this system admits a trivial solution for which \(\rho = \text{const}\) and \(u = \text{const}\). We shall call such a solution a "plateau". It is convenient to transform the system (54) to a diagonal Riemann form
\[
\frac{\partial \rho_{\pm}}{\partial t} + v_{\pm} \frac{\partial \rho_{\pm}}{\partial x} = 0, 
\] (55)
by defining the Riemann invariants and Riemann velocities
\[
\begin{align*}
\rho_{\pm} &= u + \frac{\delta \rho}{2} \pm \sqrt{(1 + \delta u)\rho}, \\
v_{\pm} &= u + \rho \pm \sqrt{(1 + \delta u)\rho},
\end{align*} 
\] (56)
where the Riemann velocities are expressed via the Riemann invariants by the relations
\[
v_{\pm} = \frac{3}{2} r_{\pm} + \frac{1}{2} r_{\pm}, \quad v_{-} = \frac{1}{2} r_{\pm} + \frac{3}{2} r_{\pm}. 
\] (57)

It is clear that the system is modulationally unstable if
\[
u < - \frac{1}{\delta}. 
\] (58)

A rarefaction wave belongs to the class of simple wave solutions. For such a solution, one of the Riemann invariants is constant, and this condition either \(r_+ = \text{const}\) or \(r_- = \text{const}\) gives, when applied to Eqs. (56), relationship between the variables \(\rho\) and \(u\). Consequently, on the \((u, \rho)\)-plane these simple wave solutions are depicted as curves (see Fig. 1)
\[
\rho = 2 + 2 \delta r_{\pm} + \delta u \pm 2 \sqrt{(1 + 2 \delta r_{\pm})(1 + \delta u)/\delta^2}. 
\] (59)

To have the intensity positive, it is necessary to fulfill the condition \(-1/(2\delta) \leq r_- \leq r_+\). Both curves touch the boundary line \(u = -1/\delta\) of the instability region. In Fig. 1 the modulationally unstable region (58) is grey. Along the line \(\rho = (1 + \delta u)/\delta^2\) both derivatives \(\partial r_+/\partial u = 0, \partial r_+/\partial \rho = 0\) vanish. We say that this line separates two monotonicity regions in the half-plane \(\rho \geq 0\) (see Fig. 1). The two intersection points of curves correspond to uniform flows with constant parameters \(\rho = \text{const}\) and \(u = \text{const}\), that is to the plateau solutions. It is easy to express the physical variables \(\rho\) and \(u\) in terms of \(r_-\), \(r_+\),
\[
\begin{align*}
\rho &= \frac{1}{\delta^2} \left(1 + \delta(r_+ + r_-) \pm \sqrt{(1 + 2\delta r_+)(1 + 2\delta r_-)}\right), \\
u &= \frac{1}{\delta} \left(\delta(r_+ + r_-) - 1 \mp \sqrt{(1 + 2\delta r_+)(1 + 2\delta r_-)}\right). 
\end{align*} 
\] (60)

The initial profiles (53) being infinitely sharp, do not involve any characteristic length. Therefore the large scale features of the solution of this problem can depend on the self-similar variable \(\zeta = x/t\) only, that is \(r_\pm = r_\pm(\zeta)\), and then the system (55) reduces to
\[
(v_+ - \zeta) \frac{dr_+}{d\zeta} = 0, \quad (v_- - \zeta) \frac{dr_-}{d\zeta} = 0. 
\] (61)

We note again that these equations have a simple solution \(r_- = \text{const}\), \(r_+ = \text{const}\) with constant \(u\) and \(\rho\) which corresponds to the mentioned above plateau region.

Turning to self-similar simple wave solutions, let us consider for definiteness the case when \(r_- = \text{const}\). Then \(r_+\) changes in such a way that the term between parenthesis in the right equation (61) is zero \((v_+ = \zeta)\), so we

FIG. 1. Relation between \(\rho\) and \(u\) for the simple wave solutions in the dispersionless regime. One line corresponds to \(r_- = \text{const}\) (blue), and another one to \(r_+ = \text{const}\) (red). Gray area shows the modulationally unstable region.
dependence of the Riemann invariants on the physical values of the corresponding Riemann invariants. This type of wave can connect uniform flows with equal curvatures. The edge velocities of these rarefaction waves are equal to

$$\begin{align*}
    (a) & \quad s_- = \frac{1}{2} t^L + \frac{3}{2} t^R, \quad s_+ = \frac{1}{2} t^R + \frac{3}{2} t^R, \\
    (b) & \quad s_- = \frac{3}{2} t^L + \frac{1}{2} t^R, \quad s_+ = \frac{3}{2} t^R + \frac{1}{2} t^R.
\end{align*}$$

Obviously, the corresponding wave structures must satisfy the conditions (a) \( t^L < t^R \), \( t^L = t^R \) or (b) \( t^L = t^R \), \( t^L < t^R \). The other two situations with opposite inequalities result in multi-valued solutions and are therefore nonphysical: the dispersionless approximation is not applicable to these cases and we have to turn to another type of key elements for describing such structures.

### 4.2. Cnoidal dispersive shock waves

The other two possible solutions of Eqs. (55) are sketched in Fig. 4, where for future convenience we have made the change \( r \rightarrow \lambda \) (\( r \) will be functions of \( \lambda \) defined below), and they satisfy the boundary conditions (a) \( \lambda^L_+ = \lambda^R_+ \), \( \lambda^L_- > \lambda^R_- \) or (b) \( \lambda^L_+ > \lambda^R_+ \), \( \lambda^L_- = \lambda^R_- \). We consider \( \lambda^i \) as four Riemann invariants of the Whitham system that describe evolution of a modulated nonlinear periodic wave. We interpret this as a formation of cnoidal dispersive shock wave from the initial discontinuity with such a type of the boundary conditions.

Since the pioneering work of Gurevich and Pitaevskii, it is known that wave breaking is regularized by the replacement of the nonphysical multi-valued dispersionless solution by a dispersive shock wave. This wave pattern can be represented approximately as a modulated nonlinear periodic wave which parameters \( \lambda^i \) change slowly along the wave structure. In this case, the two dispersionless Riemann invariants \( \lambda^i_\pm \) (or \( r^\pm \)) are replaced in the DSW region by four Riemann invariants \( \lambda^i \). In this region, the evolution of the DSW is determined by the Whitham equations (47). If we consider a self-similar...
solution, then all Riemann invariants depend only on 
\( \zeta = x/t \), and the Whitham equations reduce to

\[
(v_i - \zeta) \frac{d\lambda_i}{d\zeta} = 0, \quad i = 1, 2, 3, 4. \tag{67}
\]

Hence we find again that only one Riemann invariant varies along the DSW, while the other three are constant, that is the corresponding diagram reproduces the picture shown in Fig. 4. The limiting expressions for the Whitham velocities must coincide with expressions for dispersionless Riemann velocities and therefore we can relate the corresponding dispersionless and dispersive Riemann invariants by the formulas

\[
\begin{align*}
(a) & \quad \lambda^-_L = \sqrt{1 + 2\delta r_-}, \quad \lambda^+_L = \sqrt{1 + 2\delta r_+}, \\
(b) & \quad \lambda^-_R = \sqrt{1 + 2\delta r_-}, \quad \lambda^+_R = \sqrt{1 + 2\delta r_+},
\end{align*}
\tag{68}
\]

at the soliton edges of the DSW. Here \( r_{\pm L/R} \) are the Riemann invariants of the dispersionless theory that are defined by Eqs. (56). They describe the plateau solution at the soliton edge of the DSW. In a similar way, at the small-amplitude edges we find similar relations

\[
\begin{align*}
(a) & \quad \lambda^-_L = \sqrt{1 + 2\delta r_-}, \quad \lambda^+_L = \sqrt{1 + 2\delta r_+}, \\
(b) & \quad \lambda^-_R = \sqrt{1 + 2\delta r_-}, \quad \lambda^+_R = \sqrt{1 + 2\delta r_+}.
\end{align*}
\tag{69}
\]

Again the limiting expressions coincide with the dispersionless expressions for dispersionless Riemann velocities, and therefore we can relate the corresponding dispersionless and dispersive Riemann invariants by the formulas

\[
\begin{align*}
(a) & \quad v_3(\lambda^-_L, \lambda^+_R, \lambda'_3, \lambda'_4) = \zeta ; \\
(b) & \quad v_2(\lambda^-_L, \lambda_2(\zeta), \lambda'_L, \lambda'_L) = \zeta ,
\end{align*}
\tag{71}
\]

which define the dependence of the Riemann invariants (modulation parameters) \( \lambda'_3 \) or \( \lambda'_2 \) on \( \zeta \) in implicit form. The edges of the DSW propagate with velocities

\[
\begin{align*}
(a) & \quad s_- = \frac{1}{\delta} + \frac{1}{4\delta} \left( (\lambda^-_L)^2 + 2(\lambda^+_R)^2 + (\lambda'_3)^2 \right), \\
(b) & \quad s_+ = -\frac{1}{4\delta} \left( (\lambda'_L)^2 - (\lambda'_R)^2 \right)^2 + \frac{1}{4\delta} \left( (\lambda'_L)^2 - (\lambda'_R)^2 \right)^2 ;
\end{align*}
\tag{72}
\]

As shown in the diagrams Fig. 4, three of the four Riemann invariants \( \lambda_i \) in DSW are equal to the values of Riemann invariants on the boundaries. Moreover, the third invariant changes according to (71). Substitution of \( \lambda_i \) determines the dependence of \( v_i \) on \( \zeta \) for each of the cases in (27) and (28). This means that there are two mappings from Riemann invariants to the physical parameters. This point will be important in classification of the wave structures evolved from the initial discontinuities. For example, let us consider the case (a) \( \lambda'_L = \lambda'_R, \lambda'_L > \lambda'_R \). We have two paths on the \((u, I)\)-plane that satisfy this choice. These two paths \( L_1 \to R_1 \) and \( L_2 \to R_2 \) are shown in Fig. 5 and correspond to two mappings (27) and (28), where points \( L_1 \) and \( L_2 \) correspond to the left boundary condition with the Riemann invariants equal to \( \lambda'_L \) and \( \lambda'_L \), and the points \( R_1 \) and \( R_2 \) correspond to the right boundary condition with the Rie-
mann invariants equal to $\lambda_R^L$ and $\lambda_R^R$. In Fig. 6 we compare the analytic solution in the Whitham approximation with the exact numerical solution of the generalized CLL equation. One can see that the envelope functions resulting from the Whitham approach (dashed black lines) agree very well with the exact numerical solution (thick red lines).

In a similar way, the diagram Fig. 7(b) produces two other wave structures.

4.3. Contact dispersive shock waves

We now turn to the study of the situation where the left and right boundaries points belong to different monotonicity triangles. First, we consider the situation in which the Riemann invariants have equal values at both edges of the shock, i.e., when $r_L^L = r_R^L$, $r_L^R = r_R^R$ and, consequently, $\lambda_L^L = \lambda_R^L$, $\lambda_L^R = \lambda_R^R$. This situation resembles the one of so-called ‘contact discontinuities’ which play an important role in the theory of viscous shocks (see, e.g., Ref. [57]); therefore we shall denote the wave structures arising in this case as contact dispersive shock waves. Such waves can arise only if the boundary points are located on the opposite sides of the line $\rho = (1 + \delta \rho)/\delta^2$, i.e. in different regions of monotonicity. (To avoid any confusion, we should mention that in the dynamics of immiscible condensates, interfaces between two components may appear which play the same role as the one played by contact discontinuities in the theory of viscous shocks; see, e.g., [58]). The corresponding diagram is shown in Fig. 7.

We see that two Riemann invariants are constant within the shock region and they match the boundary condition $\lambda_L = \lambda_R^L = \lambda_R^R$, $\lambda_R = \lambda_L^R = \lambda_R^R$. Whereas the two other Riemann invariants are equal to each other ($\lambda_1 = \lambda_2$) and satisfy the same Whitham equation with $v_1(\lambda_L, \lambda_1, \lambda_L^L, \lambda_L^R) = v_2(\lambda_1, \lambda_1, \lambda_L^L, \lambda_L^R) = \zeta$. Here $\zeta$ varies within the interval $s_- \leq \zeta \leq s_+$ with

$$
s_- = -\frac{1}{\delta} - \frac{1}{4\delta^2} \frac{(\lambda_L^L)^2 - (\lambda_R^L)^2}{(\lambda_L^R)^2 - (\lambda_R^R)^2},
$$

$$
s_+ = -\frac{1}{\delta} + \frac{1}{4\delta^2} \frac{(3(\lambda_L^R)^2 + (\lambda_R^R)^2)}{(\lambda_L^R)^2 - (\lambda_R^R)^2}. \tag{73}
$$

As in the case of cnoidal DSWs, due to different mappings [27] or [28], the single contact diagram corresponds to two DSW structures. Example of two paths $P_1 \rightarrow P_2$ and the opposite $P_2 \leftarrow P_1$ is shown in Fig. 8. The corresponding wave structure is shown in Fig. 9.

4.4. Combined shocks

It is natural to ask what happens if one of the Riemann invariants still remains constant ($r_L^L = r_R^R$ or $\lambda_L^R = \lambda_R^R$),
however the boundary values of the other Riemann invariant are different: \( r^L < r^R (\lambda^L > \lambda^R) \) or \( r^L > r^R (\lambda^L < \lambda^R) \)). Diagrams for Riemann invariants for both of these cases are shown in Fig. 11. To be definite, we shall consider two generalizations of the situation. The transition of the type \( L_1 \rightarrow R_1 \) or \( L_2 \rightarrow R_2 \) of Fig. 8 can be generalized in two ways represented in Fig. 11 where the points \( L_r \) and \( R_r \) symbolize plateaus at the left and right boundaries, respectively. In this case the boundary points are also located in different monotonicity regions.

In the case corresponding to Fig. 11(a) the contact trigonometric DSW is attached at its right edge to the cnoidal DSW. At the right soliton edge the cnoidal wave matches with the right boundary plateau. The velocities of the characteristic points identified in Fig. 10(a) are given by

\[
\begin{align*}
  s_{-} &= \frac{1}{\delta} - \frac{1}{4\delta} \left( \left( \lambda^+ \right)^2 - \left( \lambda^- \right)^2 \right), \\
  s_{-}^{(1)} &= \frac{1}{\delta} - \frac{1}{4\delta} \left( \left( \lambda^+ \right)^2 + \left( \lambda^- \right)^2 \right), \\
  s_{-}^{(2)} &= \frac{1}{\delta} + \frac{1}{4\delta} \left( 3\left( \lambda^+ \right)^2 + \left( \lambda^- \right)^2 \right), \\
  s_+ &= \frac{1}{\delta} + \frac{1}{4\delta} \left( \left( \lambda^+ \right)^2 + 2\left( \lambda^+ \right)^2 + \left( \lambda^+ \right)^2 \right).
\end{align*}
\]

The resulting composite wave structure is shown in Fig. 12(a) (thin blue line) where it is compared with the numerical solution of the generalized CLL equation (thick red line).

In the case corresponding to Fig. 11(b) the contact DSW is attached at its soliton edge to the rarefaction wave which matches at its right edge with the right boundary plateau. The velocities of the characteristic points identified in Fig. 10(b) are expressed in terms of the boundary Riemann invariants by the formulas

\[
\begin{align*}
  s_{-} &= \frac{1}{\delta} - \frac{1}{4\delta} \left( \left( \lambda^+ \right)^2 - \left( \lambda^+ \right)^2 \right), \\
  s_{-}^{(1)} &= \frac{1}{\delta} + \frac{1}{4\delta} \left( 3\left( \lambda^+ \right)^2 + \left( \lambda^+ \right)^2 \right) \frac{1}{\delta} + \frac{1}{4\delta} \left( \left( \lambda^+ \right)^2 \right), \\
  s_{-}^{(2)} &= \frac{1}{\delta} + \frac{1}{4\delta} \left( 3\left( \lambda^+ \right)^2 + \left( \lambda^+ \right)^2 \right). \\
\end{align*}
\]

The resulting composite wave structures are shown in Fig. 12(b) (thin blue lines) where they are compared with the numerical solution of the generalized CLL equation (thick red line).

This completes the characterization of all the key elements which may appear in a complex wave structure evolving from an arbitrary initial discontinuity of type...
We can now proceed to the classification of all the possible composite structures.

5. CLASSIFICATION OF WAVE PATTERNS

Now we turn to the Riemann problem. This problem arose long ago and it remains an active area of research nowadays (see, e.g., [59–61]). As was noted above, one of the simplest cases is the KdV equation, where there are only two possible ways of evolution of initial discontinuity — it can evolve into either rarefaction wave or cnoidal DSW. It was shown that the NLS equation evolution of any initial discontinuity leads to a wave pattern consisting of a sequence of building blocks two of which are represented by either the rarefaction wave or the DSW, and they are separated by plateau, or vacuum, or two-phase self-similar solution close to unmodulated nonlinear periodic wave. In total, there are six different possible wave patterns that can evolve from a given initial discontinuity. Similar classification of wave patterns was also established for the dispersive shallow water Kaup-Boussinesq equation [52, 53]. For classification of wave patterns arising in solutions of the Riemann problem of the KdV or NLS type, it is important that the corresponding dispersionless limits are represented by the genuinely nonlinear hyperbolic equations. If it is not the case, then the classification of the KdV-NLS type becomes insufficient and it was found that it should include new elements — kinks, trigonometric dispersive shocks or combined shocks. An example of such equations can be the modified KdV [61], Gardner [53] or Miyata-Camassa-Choi [59] equations. These new elements can be labeled by two parameters only and therefore these possibilities can be charted on a two-dimensional diagram. In our present case the initial discontinuity [53] is parameterized by four parameters $u^L$, $u^R$, $\rho^R$, $\rho^L$, hence the number of possible wave patterns considerably increases and it is imposible to present them in a two-dimensional chart. Therefore it seems more effective to formulate the principles according to which one can predict the wave pattern evolved from a discontinuity with given parameters. Similar method was used [53, 52] in classification of wave patterns evolving from initial discontinuities according to the generalized NLS equation and the Landau-Lifshitz equation.

As is clear from the previous section, it is convenient to distinguish the situations where both points representing the left and right boundary conditions belong to the same region of monotonicity from those where they belong to different such regions (see Fig. 13). It is convenient to begin with the consideration of the classification problem from the case when both boundary points lie on one side of the line $\rho = (1 + \delta u)/\delta^2$ separating two monotonicity regions in the $(u, \rho)$-plane. For definiteness, we denote the point of coordinates $(u_L, \rho_L)$ referring to the left boundary by $L$ and plot the two curves of constant Riemann invariants $\lambda_+^L$ and $\lambda_-^L$. These divide the region into six sub-domains. It is easy to see that, when the point $R$ referring to the right boundary is located in one of these domains (labelled by the symbols A, B, ..., F), one of the following inequalities is fulfilled:

\begin{align}
A : & \lambda_-^R < \lambda_+^R < \lambda_-^L < \lambda_+^L, \\
B : & \lambda_-^R < \lambda_-^L < \lambda_+^L < \lambda_+^R, \\
C : & \lambda_-^L < \lambda_-^R < \lambda_-^L < \lambda_-^L, \\
D : & \lambda_-^L < \lambda_-^L < \lambda_+^L < \lambda_+^R, \\
E : & \lambda_-^L < \lambda_-^R < \lambda_+^L < \lambda_+^L, \\
F : & \lambda_-^L < \lambda_+^L < \lambda_-^L < \lambda_+^R.
\end{align}

(76)

The corresponding sketches of wave structures are shown in Fig. 14. In cases (A)–(E) two elementary wave structures presented in the previous section are connected by a plateau whose parameters are determined by the dispersionless Riemann invariants $\lambda_+^L$ equal to $\lambda_+^R$ and $\lambda_-^L = \lambda_-^R$. In case (F) two rarefaction waves are separated by a region with intensity and chirp which are expressed by formulas

$$\rho = \frac{1 + \delta \zeta}{\delta^2}, \quad u = -\frac{1}{\delta}.$$  

(77)

The last property is a feature of the generalized CLL equation [2], since similar behaviour for intensity (density for Bose-Einstein condensates or depth for water waves) was not previously observed.

Let us look at each case separately:

- In case (A) two DSWs are produced with a nonlinear wave which can be presented as a non-modulated cnoidal wave between them. Evolution of wave structure is shown in Fig. 14(A).
- In case (B) two DSWs are produced with a plateau between them. Here we have a collision of two light fluids (see Fig. 14(B)).
- In case (C) we obtain a dispersive shock wave on the right, a rarefaction wave on the left and a plateau in between are produced (see Fig. 14(C)).

\begin{figure}
\centering
\includegraphics[width=\textwidth]{fig13.png}
\caption{Domains in the upper left monotonicity region of the $(u, \rho)$-plane corresponding to different wave structures.}
\end{figure}
• In case (D) we get the same situation as in case (C), but now the dispersive shock wave and rarefaction wave exchange their places (see Fig. 14(D)).

• In case (E) two rarefaction waves are connected by a plateau. Here rarefaction waves are able now to provide enough flux of the light fluid to create a plateau in the region between them (see Fig. 14(E)).

• In case (F) two rarefaction waves are combined into a single wave structure where they are separated by a region with parameters varying according to (77). This means that two light fluids flow in opposite directions with velocities so large that the rarefaction waves are not able to form a plateau between them. Sketch of wave structure is shown in Fig. 14(F).

Now we turn to consideration of the classification problem for the case when both boundary points lie below and to the right of the line $\rho = (1 + \delta u)/\delta^2$. This situation is shown in Fig. 15. We see that the curves divide again this right monotonicity region into six domains. For this case the Riemann invariants can have the same orderings as in the previous case. Depending on the location of the right boundary point in a certain domain, the corresponding wave structure will be formed. For all cases these structures coincide with those for the previous case. The only difference from the previous situation is structure (F), where in this case two rarefaction waves are combined into a single wave structure where they are separated by an empty region. This means that two light fluids flow in opposite directions with velocities so large that the rarefaction waves are not able to fill in an empty region between them.

At last, we have to investigate the situation when the boundary points are located on different sides of the line $\rho = (1 + \delta u)/\delta^2$, that is in different monotonicity regions. As we have seen in the previous section, in this case new complex structures consisting of contact dispersive shock waves or combined shocks appear. Since the total number of possible wave patterns is very large, we shall not list all
of them here but rather illustrate the general principles of their classification.

For given boundary parameters, we can construct the curves corresponding to constant Riemann invariants $r_{\pm}^{L,R}$: each left or right pair of these parabolas crosses at the point $L$ or $R$ representing the left or right boundary state’s plateau. Our task is to construct the path joining these two points, then this path will represent the arising wave structure. We already know the answer for the case when the left and right points lie on the same $r$-curve. If this is not the case and the right point $R$ lies, say, below the curve $r_{R}^{L} = \text{const}$ then we can reach $R$ by means of more complicated path consisting of two curves joined at the point $P$. Evidently, this point $P$ represents the plateau between two waves represented by the curves. At the same time, each curve corresponds to a wave structure discussed in the preceding section. In fact, there are two paths with a single intersection point that join the left and right boundary points. We choose the physically relevant path by imposing the condition that velocities of edges of all regions must increase from left to right.

Having constructed a path from the left boundary point to the right one, it is easy to draw the corresponding $\lambda$-diagram. To construct the wave structure, we use the formulas connecting the zeros $\nu_i$ of the resolvent with the Riemann invariants $\lambda_i$ and expressions for the solutions parameterized by $\nu_i$. This solves the problem of construction of the wave structure evolving from the initial discontinuity with given boundary conditions.

As an example of complex wave structure, we take the boundary conditions of the form $\rho_L = 1.2$, $u_L = -0.8$, $\rho_R = 0.6$, $u_R = 0$ with $\delta = 1$. It can be seen from the top panel of Fig. 16 that such initial conditions lie in different monotonicity regions. It means that one of the waves must consist of a contact dispersive shock wave or of a combined shock wave. We have a plateau between the waves indicated by a single point $P$ in Fig. 17. This plateau is characterized by two relations between Riemann invariants $r_{L}^{R} = r_{R}^{L}$ and $r_{L}^{-} = r_{R}^{L}$. Calculating the dispersionless Riemann invariants, we arrive at the diagram shown in the bottom panel of Fig. 16. It can be seen from this figure that the wave propagated to the left consist of a cnoidal wave ($s_{1}^{L} < \zeta < s_{2}^{L}$) and a contact wave ($s_{2}^{L} < \zeta < s_{3}^{L}$). In this case, the right wave consist of a rarefaction wave only ($s_{1}^{R} < \zeta < s_{2}^{R}$). Substitution of the dispersion Riemann invariants, which are the solution of the Whitham equations, into the periodic solution gives the wave structure, which is shown in Fig. 17. For comparison, a numerical solution is shown in red. As we can see, analytical calculations agrees well with numerics.

6. CONCLUSION

In this work, the propagation of sufficiently long pulses in fibers described by the generalized Chen-Lee-Liu equation which related to the class of the nonlinear Schrödinger equations modified by self-steepening term. The Riemann problem of evolution of an initial discontinuity is solved for this specific case of non-convex dispersive hydrodynamics. It is found that the set of possible wave structures is much richer than in the convex case and includes, as structural elements, trigonometric shock combined with rarefaction waves or cnoidal dispersive shocks. In the resulting scheme, one solution of the Whitham equations corresponds to two different wave patterns, and this correspondence is provided by a two-
valued mapping of Riemann invariants to physical modulation parameters. To determine the pattern evolving from given discontinuity, we have developed a graphical method.

In principle, one may hope that the results found here can be observed experimentally in systems similar to that used in the recent experiment [31]. However, one should keep in mind that in standard fibers in addition to the self-steepening effect, Raman effect also occurs. However, the manifestations of these two effects are quite different and therefore they can be identified separately. As was shown in the article [66], the main consequence of the Raman scattering is the formation of stationary shock waves at finite length. While self-steepening leads to the formation of complex wave structures. At the same time, the generalized Chen-Lee-Liu theory is also used in the investigation of modulated wave dynamics of propagating through a single nonlinear transmission network which presents some practical interest [49]. The method presented here is quite flexible and was also applied to other systems with non-convex hydrodynamics [50,52].

ACKNOWLEDGMENTS

I would like to thanks my teacher Anatoly Kamchatnov of introducing me to this topic and for useful discussions during the work on this paper. The reported study was funded by RFBR, project number 19-32-90011.
