(Dated: August 22, 2018)

We analyze, from a canonical quantum field theory perspective, the problem of one-dimensional particles with three-body attractive interactions, which was recently shown to exhibit a scale anomaly identical to that observed in two-dimensional systems with two-body interactions. We study in detail the properties of the scattering amplitude including both bound and scattering states, using cutoff and dimensional regularization, and clarify the connection between the scale anomaly derived from thermodynamics to the non-vanishing nonrelativistic trace of the energy-momentum tensor.

I. INTRODUCTION

The existence of scaling anomalies [1, 2] in low-dimensional nonrelativistic systems and its consequences in the understanding of ultracold atoms [3–5] has recently become the subject of intense activity, both theoretically (see e.g. [6–19]) and experimentally (see e.g. [20–30]). An understanding of the virial expansion entirely within the framework of scaling anomalies was developed for two-dimensional (2D) and one-dimensional (1D) Fermi systems in Refs. [31, 32], respectively (in the 1D case, three different “flavors” of fermions were considered). In 2D, the calculation was based on a quantum field theory (QFT) path-integral representation of the partition function with a two-body local interaction, whereas for the 1D case, a judicious mapping between the quantum-mechanical 2D two-body problem and the quantum-mechanical 1D three-body problem allowed for the treatment of certain aspects of the thermodynamics and the virial expansion of the 1D case in particular the proportionality between the (interaction-induced) change in the third virial coefficient ∆b₃ in 1D and the change in the second coefficient ∆b₂ in 2D. In spite of those advances, a full-fledged QFT treatment of the partition function for the 1D three-body local interaction case is still lacking.

In this paper, we address the existence of the bound state for the 1D system using canonical QFT methods at zero temperature. Several other issues on anomalies that were addressed for the 2D system in Ref. [33] are also discussed - we follow this reference closely. Section II briefly reviews the quantum-mechanical mapping between the 2D and 1D systems (two-body and three-body respectively), including the bound-state as well as the scattering sector. Section III states some well-known aspects of nonrelativistic 1D QFT. In Sec. IV a calculation of the exact 3 → 3 scattering amplitude is performed; the pole of the amplitude allows one to display the trimer bound-state energy, as well as the running of the dimensionless coupling constant of the three-body local interaction, and the necessary renormalization is made explicit (dimensional transmutation) using a cutoff method. In the following section the same calculation is performed using dimensional regularization (DR). In Sec. VI DR is used to derive the nonrelativistic trace anomaly (dilaton anomaly) for the 1D (three-body) and the 2D (two-body) cases. Conclusions and comments are presented in Sec. VII.

II. FIRST QUANTIZATION

The 1D three-body Schrödinger equation for our system takes the form

$$\left[ -\frac{1}{2m} \left( \frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} + \frac{\partial^2}{\partial x_3^2} \right) + g \delta(x_2-x_1) \delta(x_3-x_2) \right] \psi = E \psi,$$

where $\psi = \psi(x_1, x_2, x_3)$ is the 3-body wavefunction. Performing the change of variables $Q = \frac{1}{3} (x_1 + x_2 + x_3)$, $q_1 = x_2 - x_1$, and $q_2 = \frac{1}{\sqrt{6}} (x_1 + x_2 - 2 x_3)$, the center of mass (COM) factors out and we obtain the relative equation

$$\left[ -\frac{1}{2m} \left( \frac{\partial^2}{\partial q_1^2} + \frac{\partial^2}{\partial q_2^2} \right) + \tilde{g} \delta(q_1) \delta(q_2) \right] \psi = E_r \psi,$$

where now $\psi = \psi(q_1, q_2)$, $\tilde{m} = m/2$, and $\tilde{g} = (2/\sqrt{3}) g$. We can treat Eq. (2) as a 2D problem for a single particle with mass $\tilde{m}/2$. That 2D problem is easily solved, with the result that the system possesses a bound state with energy $\tilde{E}_b$.

$$\tilde{E}_b = -\frac{\Lambda_{2D}^2}{2\tilde{m}} e^{\frac{2}{\tilde{m} \tilde{g}}},$$

where $\Lambda_{2D}$ is a cutoff required to make the 2D problem finite. After renormalization, the cutoff can be traded for a scale $\mu$ such that

$$E_b = -\frac{\mu^2}{2m} e^{\frac{2}{m \mu^2}},$$

as in Eq. (3) 

$$E_b = -\frac{\Lambda_{2D}^2}{2m} e^{\frac{2}{m \tilde{g}}}.$$
where the coupling $\tilde{g} = \tilde{g}(\mu)$ runs with $\mu$ such that the right hand side of Eq. (4) is an RG invariant. For the rest of this work we will set $m = 1$ (as we have already done with $\hbar$), such that Eq. (4) reads

$$E_b = -\mu^2 e^{2\pi/\eta}.$$  

(5)

The $T$-matrix for the 3-body problem can also be solved for using the scattering solution of the 2-problem. The exact scattering solution to Eq. (2) for a particle with incoming momentum $\vec{k}$ is

$$\phi^{in}_k(\vec{p}) = (2\pi)^2 \delta(\vec{p} - \vec{k}) + \frac{1}{E_k - E_p + i\epsilon} \left( \frac{1}{g} + \frac{\mu}{2\pi} \ln \left( \frac{A^2_{2D}}{k^2} \right) \right)^{-1},$$

where upon substituting Eq. (3), one arrives at

$$\phi^{in}_k(\vec{p}) = (2\pi)^2 \delta(\vec{p} - \vec{k}) + \frac{1}{E_k - E_p + i\epsilon} \left( \frac{2\mu E_b}{2\pi} \right)^{-1}.$$  

The $T$-matrix $\hat{T}$ can be extracted from the in-state $|\hat{k}\rangle^{in}$ projected onto $|\vec{p}\rangle$, the free state at $t \to \infty$, via the Lippmann-Schwinger relation

$$|\vec{k}\rangle^{in} = |\vec{k}\rangle + \frac{1}{E_k - H_0 + i\epsilon} \hat{T} |\vec{k}\rangle,$$  

(6)

from which comparison with $\phi^{in}_k(\vec{p})$ gives

$$\langle \vec{p}|\hat{T}|\vec{k}\rangle = \left( \frac{\mu}{2\pi} \ln \left( \frac{2\mu E_b}{k^2} \right) \right)^{-1}.$$  

(7)

Translating from the 2D problem to the 1D problem by using the mapping between 2D and 1D to take $k^2 + k_z^2 = \frac{1}{2} (p_2 - p_1)^2 + \frac{1}{2} (p_1 + p_2 - 2p_3)^2$ along with $p_1 + p_2 + p_3 = 0$ in the COM frame, one obtains $k^2 + k_z^2 = p^2 + p^2 + p^2 = E_{COM}$ such that

$$\langle \vec{p}|\hat{T}|\vec{k}\rangle = \left( \frac{2\pi}{4\pi} \ln \left( \frac{E_b}{E_{COM}} \right) \right)^{-1}.$$  

(8)

Finally,

$$\frac{\langle \vec{p}|\hat{T}|\vec{k}\rangle}{\sqrt{\langle \vec{p}|\hat{T}|\vec{k}\rangle \langle \vec{k}|\vec{k}\rangle}} = \left( \frac{1}{2\sqrt{3\pi}} \ln \left( \frac{E_b}{E_{COM}} \right) \right)^{-1}.$$  

(9)

where box normalization is used with $V_x = \sqrt{2} V_q$ and $V_x$ set to 1.

---

1 Alternatively, using the definition $\bar{\psi}(\vec{q}) \equiv \psi(\vec{x})$ implies the normalization $\langle \bar{\psi}|\psi\rangle = \int dq_1 dq_2 dq_3 \psi^\dagger(q_1) \bar{\psi}(q_2) \bar{\psi}(q_3) = \int dx_1 dx_2 dx_3 \left| \frac{\partial(q_1, q_2, Q)}{\partial(x_1, x_2, x_3)} \right| \psi^\dagger(x_1) \psi(x_2) \psi(x_3) = \left| \frac{\partial(q_1, q_2, Q)}{\partial(x_1, x_2, x_3)} \right| \int dx_1 dx_2 dx_3 \psi^\dagger(x_1) \psi(x_2)$, with the Jacobian $| \frac{\partial(q_1, q_2, Q)}{\partial(x_1, x_2, x_3)} | = \frac{2}{\sqrt{3}}$.

---

2 The label $i$ refers to “flavor” quantum number (different spins).

---

3 This is a nonrelativistic few-body ground state, such that holes/antiparticles propagating backwards in time do not exist.

---

III. BRIEF REVIEW OF FEW-BODY FIELD THEORY

![Diagram of 3-body scattering](image1)

FIG. 1: A few 3 → 3, 2-loop diagrams.

The nonrelativistic Lagrangian density corresponding to Eq. (1) is given by

$$\mathcal{L} = \sum_{i=1}^{3} \left( i \partial_t + \nabla^2 / 2 \right) \psi_i - g(\psi_i^\dagger \psi_1)(\psi_i^\dagger \psi_2)(\psi_i^\dagger \psi_3),$$  

(10)

such that the free propagator can be read off as

$$D(x, t) = \delta_{ij}(x, t) = \delta_{ij} D(x, t)$$

with

$$D(x, t) = \int d\omega dk \frac{e^{-i(\omega t - kx)}}{(2\pi)^2 \omega - k^2 / 2 + i\epsilon} = -\theta(t) \frac{e^{i(\frac{\omega^2}{2} + \frac{\omega}{2})}}{\sqrt{2\pi i}}$$  

(11)

which is nonzero only for $t > 0$, i.e. propagation forwards in time. We take tadpole graphs $D(0, 0)$ to be zero such that the vacuum contains no particles.

$$n(x) = -\lim_{\eta \to 0^+} \langle 0| T \psi(0, x) \psi^\dagger(\eta, x) |0\rangle$$  

$$= -i \lim_{\eta \to 0^+} \int d\omega dk \frac{e^{i\eta \omega}}{(2\pi)^2 \omega - k^2 / 2 + i\epsilon} = 0,$$  

(12)

where the contour is completed in the upper half of the complex $\omega$-plane, which misses the pole on the lower half. Alternatively, one can regulate the tadpole with a cutoff, and when quantizing Eq. (10), ambiguity in the ordering of the fields of the interaction term produces a chemical potential counter-term which can cancel the tadpole. Furthermore, if one uses DR, Eq. (12) is automatically zero.
This feature of propagation only forwards in time makes all diagrams with counterflowing arrows in a loop zero, as \( \theta(t_2 - t_1)\theta(t_1 - t_2) = 0 \). The vanishing of tadpole and counterflowing graphs implies that only the s-channel graphs, e.g. Fig. 1c, are nonvanishing (see Appendix A).

Moreover, the wavefunction renormalization \( Z = 1 \), as the self energy vanishes such that propagator receives no quantum corrections, as illustrated in Fig. 2.

### IV. 3 \rightarrow 3 SCATTERING AMPLITUDE

The two-loop contribution to the scattering amplitude is given by Fig. 3b corresponding to the expression

\[
A^{(2)} = (-ig)^2 \int \frac{d\omega_k d\omega_q dk dq}{(2\pi)^4} \frac{i}{(\omega_k - k^2/2 + i\epsilon)(\omega_q - q^2/2 + i\epsilon)}
\]

where \( A^{(2)} \) is only a function of \( p^2 - p^2/6 \), which is Galilean invariant. Adding the tree level-term of Fig. 3a and stringing together a product of \( A^{(2)} \)'s (see Fig. 4), one obtains the exact scattering amplitude

\[
A = \frac{-ig_0}{1 + \frac{g_0}{2\sqrt{3}\pi} \ln \left( \frac{3\Lambda^2}{p^2/6 - p_0} \right)},
\]

where the bare coupling \( g_0 \) was inserted for \( g \).

For a given \( g_0 \) and \( \Lambda \), Eq. 16 can be replaced with another \( g \) and \( \mu \) such that \( A \) is unchanged for all kinematic values of \( p_0 - p^2/6 \). This is most easily seen by considering the reciprocal of \( A \):

\[
1 + \frac{1}{2\sqrt{3}\pi} g_0 \ln \left( \frac{3\Lambda^2}{p^2/6 - p_0} \right) = 1 + \frac{1}{2\sqrt{3}\pi} g \ln \left( \frac{3\mu^2}{p^2/6 - p_0} \right)
\]

which yields

\[
g_0 = \frac{g}{1 + \frac{g}{2\sqrt{3}\pi} \ln \left( \frac{\mu^2}{\Lambda^2} \right)},
\]

where the dependence on the kinematical parameter \( p_0 - p^2/6 \) has dropped out. Therefore in Eq. 16, one can always replace bare couplings \( (g_0, \Lambda) \) by renormalized ones \( (g, \mu) \), so long as they are related by Eq. 18.

Finally, searching for the pole in Eq. 16 after going on-shell in the COM frame \( (p = \sum_i p_i = 0, p_0 = \sum_i p_i^0) \),
followed by continuing into imaginary momenta \( p_i \rightarrow ip_i \) gives the trimer bound-state energy

\[
E_b = -3\Lambda^2 e^{2\pi\sqrt{3}/\mu},
\]  

which can be made to coincide with Eq. (17) along with the identification \( \sqrt{3}\Lambda = \Lambda_{2D} \) (and similarly for \( \mu \))

\[
E_b = -\mu^2 e^{2\pi\sqrt{3}/\mu}.
\]  

The scattering amplitude \( A \) in Eq. (16) can be written entirely in terms of the bound state energy by using Eq. (19) to get rid of the coupling (dimensional transmutation)

\[
A = \frac{-i}{2\sqrt{3} \pi} \ln \left( \frac{E_b}{p_0-p^2/6} \right) = \frac{-i}{2\sqrt{3} \pi} \ln \left( \frac{E_b}{Q_0} \right).
\]  

\[
A(2) = \frac{ig^2 \mu^{4\epsilon}}{(2\pi)^{2d}} \int d^d k d^d q \frac{1}{Q_0 - k^2 - q^2 - (k+q)^2} + i\epsilon.
\]  

\[
A(2) = \frac{ig^2 \mu^{4\epsilon}}{(2\pi)^{2d}} \int d^d k d^d q \frac{1}{Q_0 - k^2 - q^2 - (k+q)^2} \gamma(1-d) - Q_0.
\]  

Denoting \( \ell = (k_1, k_2, \ldots, k_d, q_1, q_2, \ldots, q_d) \) we obtain

\[
A(2) = \frac{ig^2 \mu^{4\epsilon}}{(2\pi)^{2d}} \left( \frac{2}{\sqrt{3}} \right)^{1-\epsilon} \int d^d \ell \frac{1}{\ell^2 - Q_0},
\]  

which is a form appropriate for integration in DR. Note the \( i\epsilon \) in \( Q_6 \) so the integral does not hit a pole. Using Eq. (8.4) in Ref. [41] with \( D \rightarrow 2d \) and \( m^2 \rightarrow -Q_6 \) we obtain

\[
A(2) = ig^2 \mu^{4\epsilon} \left( \frac{2}{\sqrt{3}} \right)^{1-\epsilon} \frac{(-Q_0)^{d-1}}{(4\pi)^{d}} \Gamma(1-d) + i\epsilon \Gamma(1-d) - Q_0
\]  

\[
A(2) = ig^2 \mu^{4\epsilon} \left( \frac{2}{\sqrt{3}} \right)^{1-\epsilon} \frac{(-Q_0)^{d-1}}{(4\pi)^{d}} \Gamma(1-d) - Q_0
\]  

We use the formula \( a + ax + ax^2 + \ldots = \frac{a}{1-x} \) where \( x \) is the ratio of \( A(2) \) to \( A(0) \) to obtain the full amplitude:

\[
A = \frac{-i\mu^{2\epsilon}}{1/g + \left( \frac{2}{\sqrt{3}} \right) \frac{1}{(4\pi)^{d}} \mu^{2\epsilon} \left( \frac{2}{\sqrt{3}} \right)^{1-\epsilon} \frac{(-Q_0)^{d-1}}{(4\pi)^{d}} \Gamma(1-d)}
\]  

In the denominator we write \( \Gamma(\epsilon) = 1/\epsilon - \gamma_E \), where \( \gamma_E = 0.577\ldots \) is the Euler-Mascheroni constant, and note that \( a^* = 1 + \epsilon \ln a + O(\epsilon^2) \). In addition, we write \( 1/g = 1/g_{\overline{MS}} - \frac{1}{2\sqrt{3}\pi} \epsilon + \frac{1}{2\sqrt{3}\pi} \gamma_E + \ln \left( \frac{2}{\sqrt{3}} \right) - \ln(4\pi) \) for \( \overline{MS} \)

\[
A = \frac{-i\mu^{2\epsilon}}{1/g_{\overline{MS}} + \frac{1}{2\sqrt{3}\pi} \ln \left( \frac{\mu^{2\epsilon}}{Q_0} \right)}
\]  

Moreover, from

\[
1/g = 1/g_{\overline{MS}} - \frac{1}{2\sqrt{3}\pi} \epsilon + \frac{1}{2\sqrt{3}\pi} \gamma_E + \ln \left( \frac{2}{\sqrt{3}} \right) - \ln(4\pi)
\]  

we see that to order \( 1/\epsilon \), we can make the replacement

\[
1/g \rightarrow -\frac{1}{2\sqrt{3}\pi} \epsilon = \frac{1}{2\sqrt{3}\pi} d - 1,
\]  

which amounts to \( \frac{1-g}{g} \rightarrow \frac{1}{2\sqrt{3}\pi} \epsilon \).

Finally, we will implement dimensional transmutation in Eq. (28): in the center-of-mass frame \( (p = 0) \), after analytic continuation \( p_0 = \sum_{i=1}^{d} \frac{p_i^2}{2} \rightarrow -\sum_{i=1}^{d} \frac{p_i^2}{2} \), we find the bound state energy \( E_b = -3\sum_{i=1}^{d} \frac{p_i^2}{2} \) from the pole of Eq. (28)

\[
\frac{1}{g_{\overline{MS}}} + \frac{1}{2\sqrt{3}\pi} \ln \left( \frac{\mu^{2\epsilon}}{Q_0} \right) = 0.
\]  

Therefore,
1/g_{\text{MS}} \ln \left( \frac{\mu_{\text{MS}}^2}{Q_0^2} \right) = 1/g_{\text{MS}} \ln \left( \frac{\mu_{\text{MS}}^2}{Q_0^2} \right) + \frac{1}{2\pi \sqrt{3}} \ln \left( \frac{E_b}{Q_0^2} \right) - \frac{1}{2\pi \sqrt{3}} \ln \left( \frac{E_b}{Q_0^2} \right)

= 1/g_{\text{MS}} \ln \left( \frac{\mu_{\text{MS}}^2}{Q_0^2} \right) + \frac{1}{2\pi \sqrt{3}} \ln \left( \frac{E_b}{Q_0^2} \right)

= \frac{1}{2\pi \sqrt{3}} \ln \left( \frac{E_b}{Q_0^2} \right),

and Eq. (28) becomes

\[ A = \frac{-i}{2\pi \sqrt{3} \ln \left( \frac{E_b}{Q_0^2} \right)} \tag{33} \]

which is the same as Eq. (21).

VI. TRACE ANOMALY

As is well known, Noether’s theorem gives a constructive procedure to find conserved charges, the so-called Noether charges [43], whenever the classical action for a field theory is invariant under global symmetry transformations. In the particular case of the 1D nonrelativistic Lagrangian, Eq. (10), the following classical conservation equations, in Appendix B, in the definition of equation of motion where

\[ \partial \mu \delta \phi_i = 0, \tag{34} \]

where \( j^\mu = \left( \frac{\partial \mathcal{L}}{\partial \phi_i^*} \delta \phi_i + f^\mu \mathcal{L} \right). \) Equation (34) is derived in Appendix B. In the definition of \( j^\mu, \phi_i = (\psi_a, \psi_a^*, a = 1, 2, 3), \delta \phi_i \rightarrow \delta \psi_a = -(f^\mu \partial_a + d/2)\psi_a, f^\mu = (2\pi, \vec{x}), \) and similarly for \( \delta \psi_a^*. \) The existence of an anomaly implies that the right-hand side of the operator version of this equation will not be zero. We will calculate it here using our previous DR procedure and results. Following Ref. [34], we will also show a derivation for the integral version of the anomaly equation.

To use DR, we have to replace the coupling constant \( g \) as in Sec. V by \( g \mu^{2\epsilon} \), with \( \epsilon = 1 - d \). In this fashion, the interaction term \( \mathcal{L}_I \) is no longer invariant, only the free part \( \mathcal{L}_0 \) is. Following the procedure of Appendix B, the finite version of the variation of \( \mathcal{L}_0 \) is

\[ \delta \mathcal{L}_0 = \frac{\partial \mathcal{L}_0}{\partial \phi_i} \delta \phi_i + \frac{\partial \mathcal{L}_0}{\partial \phi_i} \partial \mu (\delta \phi_i) = -\partial \mu (\mathcal{L}_0 f^\mu). \tag{35} \]

Since \( \frac{\partial \mathcal{L}_I}{\partial (\phi_i \phi_i)} = 0 \), we can use \( \mathcal{L}_0 = \mathcal{L} - \mathcal{L}_I \) and the equation of motion \( \partial \mu \left( \frac{\partial \mathcal{L}}{\partial \phi_i^*} \right) \delta \phi_i + \frac{\partial \mathcal{L}}{\partial \phi_i} \partial \mu (\delta \phi_i) = -\partial \mu (\mathcal{L} f^\mu) + \partial \mu (\mathcal{L}_I f^\mu) + \frac{\partial \mathcal{L}_I}{\partial \phi_i} \delta \phi_i. \]

Identifying \( j^\mu = \left( \frac{\partial \mathcal{L}}{\partial \phi_i^*} \delta \phi_i + \mathcal{L} f^\mu \right), \) Eq. (36) can then be written as

\[ \partial \mu j^\mu = \partial \mu (\mathcal{L}_I f^\mu) + \frac{\partial \mathcal{L}_I}{\partial \phi_i} \delta \phi_i \rightarrow \partial \mu j^\mu = (2 + d)\mathcal{L}_I - \frac{d}{2} \partial \mu \delta \phi_i, \tag{37} \]

where we used \( \partial \mu f^\mu = (d + 2) \) and \( \delta \phi_i = -(d/2 + f^\mu \partial_a) \phi_i \) (see Appendix B).

The derivation of Eq. (37) also applies for the case of \( d = 2 \) with \( \mathcal{L} = \mathcal{L}_0 - g \langle \psi^* \psi \rangle \) [33, 41] (and its fermionic version [31]). In this case one can easily see that \( \partial \mu j^\mu \propto (d - 2), \) so classically \( \partial \mu j^\mu = 0. \) Likewise, for the Lagrangian [10] we find

\[ \partial \mu j^\mu = -2(1 - d)g\mu^{2\epsilon} \langle \psi_1^* \psi_1 \rangle \langle \psi_2^* \psi_2 \rangle \langle \psi_3^* \psi_3 \rangle. \tag{38} \]

Again, classically \( d \rightarrow 1 (\epsilon \rightarrow 0); \) no running of \( g \) gives \( \partial \mu j^\mu = 0. \) However, quantum-mechanically, \( \frac{d}{g} \rightarrow -\frac{d}{2\pi \sqrt{3}} \) as shown in Sec. V, therefore, for \( d \rightarrow 1, \) we obtain the trace (dilation) anomaly equation

\[ \partial \mu j^\mu = \frac{1}{\sqrt{3\pi}} \mu^{2\epsilon} \langle \psi_1^* \psi_1 \rangle \langle \psi_2^* \psi_2 \rangle \langle \psi_3^* \psi_3 \rangle. \tag{39} \]

Using the results of [34] we obtain

\[ 2\mathcal{H} - \hat{T}_{xx} = -\frac{1}{\sqrt{3\pi}} g^2 \langle \psi_1^* \psi_1 \rangle \langle \psi_2^* \psi_2 \rangle \langle \psi_3^* \psi_3 \rangle. \tag{40} \]

where \( \hat{T}_{ij} \) is the energy-momentum tensor and \( \mathcal{H} = \text{energy density}; \) see below. Equation (40) is the 1D analogue of the 2D version

\[ 2\mathcal{H} - \sum_{i=1}^{2} \hat{T}_{ii} = -\frac{1}{2\pi} g^2 \langle \psi_1^* \psi_1 \rangle \langle \psi_2^* \psi_2 \rangle \langle \psi_3^* \psi_3 \rangle. \tag{41} \]

5 Here and elsewhere the summation over \( i \) means summation over \( a \) and both \( \psi_a \) and \( \psi_a^* \); e.g., \( \partial \mu \delta \psi_a \rightarrow \sum_{a=1}^{d} \partial \mu \delta \psi_a + \sum_{a=1}^{d} \partial \mu \delta \psi_a^*. \)

6 Notice \( g \) is running, \( g \propto (d - 1) \) (Eq. (30)). As in the 2D case, the matrix elements of the operator on the RHS of Eq. (39) are expected to diverge as \( (d - 1)^{-1} \), rendering the matrix elements of Eq. (40) finite [36].
which can be derived using this method; see also [34]. Notice we have now replaced the classical fields $\psi_n^a$, $\psi_n^b$, by operators $\psi_n^a$, $\psi_n^b$. The RHS of Eq. (10) is the three-body analog of the Tan contact density from two-body physics [31, 34, 47–49]. This identification is made more clear following Hofmann’s derivation for the two-body physics [31, 34].

This is the classical field theory to study the bound-state and scattering behavior will be limited to the first fewest loops. We leave this for future work.

VII. CONCLUSIONS

In this paper we used perturbative methods of quantum field theory to study the bound state and scattering problem of three different species of fermions interacting via three-body local interactions in 1D. The quantum mechanical version (first quantization) and some aspects of thermodynamics were studied in Ref. [32]. A necessary summation to all orders in the $3 \to 3$ scattering matrix was performed, using both cutoff and dimensional regularization. We confirmed the results on the 1D bound state of [32] that were based on a judicious change of variables that related the 1D to the 2D similar problem.

The work by W.S.D., C.L.L. and C.R.O has been partially supported by the US Army Research Office Grant No. W911NF-15-1-0445, and the work by J.E.D. has been partially supported by the National Science Foundation under Grant No. PHY 1452635 (Computational Physics Program).

Appendix A: Vanishing of non-S-channel Graphs

We proceed to show using Fig. 5 that all internal lines leaving or entering a vertex that participate in loops must have arrows in the same direction, or else the diagram vanishes. For the sake of argument, suppose 3, 5, and

\[ \frac{d}{2} \nabla^2 \psi_n \frac{d}{g} \nabla^2 \psi_n \frac{d}{g} \nabla^2 \psi_n \frac{d}{g} \nabla^2 \psi_n \frac{d}{g} \nabla^2 \psi_n \frac{d}{g} \nabla^2 \psi_n \frac{d}{g} \nabla^2 \psi_n \]

The first term on the RHS is twice the Hamiltonian density, the second term naively vanishes when $d = 1$, and the last term vanishes upon integration over space. Performing such an integral,

\[ \int d^dx \hat{T}_{ii} = 2 \hat{H} + 2 \frac{(d-1)}{g} I \quad (44) \]

where we define the 3-body contact,

\[ I \equiv g^2 \int d^dx \left( \psi_1^i \psi_1^i \right) \left( \psi_2^i \psi_2^i \right) \left( \psi_3^i \psi_3^i \right) \quad (45) \]

and using Eq. (30) we obtain

\[ 2 \hat{H} - \int dx \hat{T}_{xx} = -\frac{1}{\sqrt{3} \pi} I \quad (46) \]

\[ \hat{T}_{ij} = \frac{1}{2} \left( \partial_i \psi_j^a \partial_j \psi_a + \partial_j \psi_j^a \partial_i \psi_a - \delta_{ij} \frac{d}{2} \nabla^2 \left( \psi_j^a \psi_a \right) \right) + 2g \delta_{ij} \left( \psi_1^a \psi_1^a \right) \left( \psi_2^a \psi_2^a \right) \left( \psi_3^a \psi_3^a \right) \quad (42) \]

variables that related the 1D to the 2D similar problem.

A derivation of the trace (dilation) anomaly in 1D and 2D was given using the DR results developed in this paper. An interesting question is how far can one go with perturbative methods in understanding the many-body behavior of the system, where there is both anomalous breaking of scale symmetry as well as spontaneous symmetry breaking. In our previous work we explored the many-body behavior of the system using a lattice approach [32]. While the simplicity of few-body allows us to get exact results with perturbative methods, we anticipate that a perturbative calculation of the many-body behavior will be limited to the first fewest loops. We leave this for future work.

ACKNOWLEDGMENTS

FIG. 5: 3-body vertex.

We proceed to show using Fig. 5 that all internal lines leaving or entering a vertex that participate in loops must have arrows in the same direction, or else the diagram vanishes. For the sake of argument, suppose 3, 5, and

\[ 7 \text{ In what follows we will omit the } \mu^{2\kappa} \text{ since it will not contribute in the } \epsilon \to 0 \text{ limit.} \]
6 participate in loops. Denoting $p_0$ and $p$ as the sum of

\[
\int d\omega_5 d\omega_6 \frac{1}{\omega_5 - k_5^2/2 + i\epsilon} \frac{1}{\omega_6 - k_6^2/2 + i\epsilon} (\omega_5 + \omega_6 - p_0) - (k_5 + k_6 - p_0)^2/2 + i\epsilon.
\]  

which vanishes when completing the contour in the upper half of the complex frequency plane as all poles are below the real axis. Note that it is not critical that both 5 and 6 participate in loops: we only need one of the internal lines to participate in a loop in order to force the remaining internal lines to be in the same direction.

**Appendix B: Symmetries of the Action and Noether’s current Equation**

Consider the action

\[
S[\phi_i, V, T] = \int_{VT} dx \mathcal{L}(\phi_i(x), \partial_\mu \phi_i(x)),
\]

where the only spacetime dependence will be through the fields $\phi_i(x)$, $dx$ represents the spacetime measure $dx \equiv d^4xdt$ ($VT$ is the spacetime volume; $V$ usually taken to be very large). The action is to be symmetric under the simultaneous transformation of the coordinates and the fields ($R_{ij}$ will be taken to be spacetime independent)

\[
x'^\mu = x'^\mu(x'), \\
\phi_i'(x') = R_{ij} \phi_j(x), \\
\phi_i(x) = R_{ij} \phi_j(x^{-1}),
\]

such that

\[
S[\phi'_i, V', T'] = S[\phi_i, V, T],
\]

\[
\int_{V'T'} dx' \mathcal{L}(\phi'_i(x'), \partial'_\mu \phi'_i(x')) = \int_{VT} dx \mathcal{L}(\phi_i(x), \partial_\mu \phi_i(x)).
\]

the frequencies and momenta of 1, 2, and 4, respectively, then the loop integrals are proportional to

Going from $V'T'$ to $VT$ will produce a Jacobian

\[
\int_{VT} dx \frac{\partial x'}{\partial x} \mathcal{L}(R_{ij} \phi_j(x), \left(\frac{\partial x'}{\partial x^\mu}\right) \partial_\mu R_{ij} \phi_j(x))
\]

\[
= \int_{VT} dx \mathcal{L}(\phi_i(x), \partial_\mu \phi_i(x))
\]

or simply

\[
\left|\frac{\partial x'}{\partial x}\right| \mathcal{L}(R_{ij} \phi_j(x), \left(\frac{\partial x'}{\partial x^\mu}\right) \partial_\mu R_{ij} \phi_j(x)) = \mathcal{L}(\phi_i(x), \partial_\mu \phi_i(x)).
\]

Let us consider an infinitesimal transformation, $R_{ij} = \delta_{ij} + \eta r_{ij}$, such that

\[
x'^\mu = x'^\mu + \eta f^\mu(x', \eta),
\]

where $f^\mu = (2t, \vec{x})$, $r_{ij} = -\frac{d}{dt} \delta_{ij}$, and so

\[
\phi'_i(x') = \phi_i(x) + \eta r_i \phi_j(x) \\
\phi_i'(x) = \phi_i(x) + \eta r_i \phi_j(x) - \eta f^\nu \partial_\nu \phi_i(x).
\]

Then,

\[
\frac{\partial x'^\mu}{\partial x^\nu} = \delta^\mu_\nu + \eta (\partial_\nu f^\mu),
\]

such that

\[
\left|\frac{\partial x'}{\partial x}\right| = 1 + \eta \partial_\nu f^\mu + O(\eta^2),
\]

and

\[
R_{ij} \phi_j(x) = (\delta_{ij} + \eta r_{ij}) \phi_j(x) \\
= \phi_i(x) + \eta (\delta_\nu \phi_i(x) + f^\nu \partial_\nu \phi_i(x)),
\]

where we have defined $\eta \delta \phi_i(x) = \phi_i'(x) - \phi_i(x)$ such that

\[
\delta \phi_i(x) = r_i \phi_j(x) - f^\nu \partial_\nu \phi_i(x),
\]

and

\[
\delta \partial_\mu \phi_i(x) = \partial_\mu \delta \phi_i(x) = r_i \partial_\mu \phi_j(x) - \partial_\mu (f^\nu \partial_\nu \phi_i(x)).
\]

When the above is replaced into Eq. (B4) to order $\eta$ we obtain

\[
\left|\frac{\partial x'}{\partial x}\right| \mathcal{L}(\phi_i(x) + \eta \delta \phi_i(x) + \eta f^\nu \partial_\nu \phi_i(x), \partial_\mu (\phi_i(x) + \eta \delta \phi_i(x) + \eta f^\nu \partial_\nu \phi_i(x)) - \eta (\partial_\mu f^\nu) \partial_\nu \phi_i(x)) = \mathcal{L}(\phi_i(x), \partial_\mu \phi_i(x)).
\]
Performing a Taylor expansion and keeping only terms to order $\eta$ gives

$$0 = \eta \partial_v f^\nu \mathcal{L} + \eta \frac{\partial \mathcal{L}}{\partial \phi_i(x)} \{ f^\nu \phi_i(x) + f^\nu \partial_v \phi_i(x) \} + \eta \frac{\partial \mathcal{L}}{\partial \mu \phi_i(x)} \{ \partial_v \phi_i(x) + f^\nu \partial_v \phi_i(x) \} ,$$

(B13)

leading to the desired expression

$$\delta \mathcal{L} = \frac{\partial \mathcal{L}}{\partial \phi_i(x)} \delta \phi_i(x) + \frac{\partial \mathcal{L}}{\partial \mu \phi_i(x)} \partial_v \delta \phi_i(x) = -\partial_v \left( f^\nu \mathcal{L} \right).$$

(B14)

Using the equation of motion $\frac{\partial \mathcal{L}}{\partial \phi_i(x)} = \partial_\nu \frac{\partial \mathcal{L}}{\partial \mu \phi_i(x)}$, this leads to Noether’s current equation

$$\partial_\mu j^\mu = \partial_\nu \left[ \frac{\partial \mathcal{L}}{\partial \mu \phi_i(x)} + f^\nu \mathcal{L} \right] = 0.$$
