General experimental procedures

$^1$H NMR (400 MHz), $^{13}$C NMR (100 MHz) and $^{19}$F NMR (376 MHz) spectra were recorded on a JEOL 400 MHz instrument (JEOL RESONANCE Inc., Tokyo, Japan). Chemical shifts were referenced to residual solvent peaks and are given as follows: chemical shift ($\delta$, ppm), multiplicity (s, singlet; br, broad; d, doublet, t, triplet; q, quartet; m, multiplet), coupling constant (Hz), integration. LC-MS analysis was carried out using an analytical Dionex UltiMate 3000 HPLC instrument (Dionex Softron GmbH, Germering, Germany) coupled to a Thermo Finnigan LCQ DECA XP MAX mass spectrometer (Thermo ELECTRON CORPORATION, San Jose, California, USA). HR-ESI-MS analyses were performed at the Organisch Chemisches Institut WWU Münster, Germany or at the Stenhagen Analyslab AB, Mölndal. All compounds displayed the expected isotope distribution pattern. Anhydrous CH$_2$Cl$_2$ was obtained by distillation from CaH$_2$ under an Ar atmosphere.

Compounds 1 [1], 6 [1], L1$^\text{Car}$ [1], LnL1$^\text{Car}$ (Ln = Eu, Gd, Tb) [1] and L1d$^\text{Cou}$ [2] were synthesized following literature methods. All other chemicals were from commercial sources (Sigma Aldrich, St. Louis, Missouri, USA or Fluorochem, Hadfield, UK) and used as received.

**Paramagnetic $^1$H NMR.** $^1$H NMR spectra of Eu-complexes were recorded at 400 MHz using the following parameters: cooling for 5 min until the temperature stabilizes at 0±0.1 °C for samples measured in CD$_3$OD and at 10±0.1 °C for samples measured in D$_2$O; relaxation delay: 1 s; number of scans: 128; number of points: 131,072; range: –60 to 60 ppm. For Yb complexes measured at r.t. the number of points were 524,288 and the range was from –240 to 240 ppm.

**Chromatography.** Preparative chromatography was carried out on silica gel [Normasil 60 chromatographic silica media (40–63 micron)] and aluminum oxide [activated, neutral,
Brockmann Activity I, Sigma-Aldrich (Sigma Aldrich, St. Louis, Missouri, USA)]. Thin layer chromatography was performed on silica-coated (60G F254) aluminum plates from Merck and aluminum oxide coated with 254 nm fluorescent indicator aluminum plates from Sigma-Aldrich. Samples were visualized by UV-light (UVP LLC, Upland, California, USA) (254 and 365 nm).

HPLC-analysis was performed on a Dionex UltiMate 3000 system (Dionex Softron GmbH, Germering, Germany) using a Phenomenex Gemini® C18 TMS end-capped 150 mm×4.6 mm HPLC column with HPLC water (0.05% formic acid): CH$_3$CN (0.05% formic acid) eluent system using the methods: (a) 0–8 min: 10→20% & 8–12 min: 20% iso & 12–16 min 20→90% CH$_3$CN, 0.5 mL/min; (b) 0–8 min: 10% iso & 8–12 min: 10%→50% & 12–16 min 50%→90% CH$_3$CN, 0.25 mL/min. UV- (UltiMate 3000 Photodiode Array Detector (Dionex Softron GmbH, Germering, Germany)) and ESI-MS detections (Thermo Finnigan LCQ DECA XP MAX (Thermo ELECTRON CORPORATION, San Jose, California, USA)) were used. Semi-preparative HPLC was performed on Dionex UltiMate 3000 system (Dionex Softron GmbH, Germering, Germany) using a Phenomenex Gemini® C18 TMS end-capped 150 mm×30 mm HPLC column with water (0.05% formic acid): MeOH (0.05% formic acid) eluent system with the same UV-detection. The method utilised for semi-preparative purification was the following: 0–6 min: 14% iso & 6–9 min: 95% iso & 9–12 min: 14% iso MeOH, 25 mL/min.

Electrochemistry. Cyclic voltammograms (CV) were obtained in an argon atmosphere at room temperature (~20 °C) using an AUTOLAB PGSTAT 100 potentiostat, or an AUTOLAB PGSTAT 204N potentiostat, equipped with a 3 mm glassy carbon (GC) working electrode, a Pt wire auxiliary electrode, and a saturated calomel electrode (SCE) as a reference. The solution was stirred in between each measurement. The solution was let to equilibrate for 10 s at the start potential before starting the measurements. A step potential of −0.9 mV was used.
for 50, 100 and 200 mV/s scan rates, and of ~2 mV was used for 500 and 1000 mV/s scan rates. For measurements in aqueous media the supporting electrolyte was LiCl (0.1 M), in case of non-aqueous (DMF) solutions it was TBAPF$_6$ (0.1 M).

General procedure for CV measurements in water: a solution of LiCl (0.1 M) was prepared and pH was set to ~6.5 by addition of NaOH (0.1 M) or HCl (0.1 M). This solution was added to the electrochemical cell, allowed to stir, and purged with argon for 10 min prior to each measurement. The working electrode was polished with 0.05 µm alumina on a polishing pad, washed with water and ethanol, and dried with air. The three electrodes (GC working electrode, Pt wire auxiliary electrode, and SCE reference electrode) were inserted into the cell setup and a background scan was recorded with a scan rate of 100 mV/s, and four sweeps. A lack of oxygen redox signal verified that oxygen had been removed below detectable levels. The Eu complex (1 mM) was added in the solution, and the pH of the resulting solution was adjusted to ~6.5 (Table S1) by addition of NaOH (0.1 M) or HCl (0.1 M). The resulting solution was stirred and purged with argon for 10 min. Scans were recorded at various scan rates (50 to 1000 mV/s) with four sweeps for each measurement. The voltammograms obtained at various scan rates are shown in Figures S28–34. The anodic and cathodic peak current intensities ($I_{pa}$ and $I_{pc}$ respectively) were plotted vs. the square root of scan rate and fit to a linear regression to ensure that the electron transfer was heterogenous.

General procedure for CV measurements in DMF: a sample of TBAPF$_6$ (194 mg) was dissolved in 5 mL of DMF (0.1 M) and purged with argon for 10 minutes. After detecting blank signal without oxygen redox events, the CVs were recorded as it is described in the procedure for aqueous media, with 1 mM concentration of Eu complex. At the end of each experiment a sample of Ferrocene (Fc) was added at the tip of the spatula into the electrochemical cell to adjust potentials according to Fc$^0$/Fc$^+$ redox events vs SCE which was
then shifted according to the difference vs NHE [3]. The cyclic voltammograms of increasing scan rates are displayed in Figures S35–41.

**UV-Vis absorption and emission spectroscopy.** All measurements were performed in PIPES-buffered HPLC water or D$_2$O at pH 6.5 or pD 6.5. [LnL] was nominally 10 µM, however, small quantities of Ln salts may diminish this. Glycerol was of 99.9+% purity. Quartz cells with 1 cm optical pathlengths were used for the room temperature measurements. The absorbance spectra were measured by a Varian Cary 100 Bio UV-Visible spectrophotometer (VARIAN AUSTRALIA PTY LTD, Mulgrave, Victoria, Australia). The emission and excitation spectra, lifetimes, time-resolved spectra and quantum yields were recorded on a Horiba FluoroMax-4P (HORIBA Jobin Yvon, Edison, New Jersey, USA). All emissions were corrected by the wavelength sensitivity (correction function) of the spectrometer. All measurements were performed at room temperature unless stated otherwise.

Quantum yields were measured at room temperature, using quinine sulfate (QS) in H$_2$SO$_4$ 0.05 M (Φ$_{ref}$ = 0.59) as reference [4] in Equation S1. Quantum yields were calculated according to (3), with Φ$_s$ the quantum yield of the sample, Φ$_{ref}$ the quantum yield of the reference, I the integrated corrected emission intensity of the sample (s) and of the reference (ref), f$_A$ the absorption factor of the sample (s) and of the reference (ref) at the excitation wavelength and n the refractive indexes of the sample (s) and of the reference (ref). The concentration of the complexes was adjusted to obtain an absorbance around the maxima of the antennae matching that of the QS fluorescence standard. The excitation wavelength where the absorption factors of the samples and of the reference were the same was chosen (i.e. where the absorptions are identical). The corrected emission spectra of the sample and reference standard were then measured under the same conditions over the 330–800 nm (320-800 nm for carbostyril complexes) spectral range as well as blank samples containing only the solvent (i.e. PIPES-buffered aqueous solutions). The appropriate blanks were subtracted from
their respective spectra, and the antenna fluorescence and Ln(III) luminescence were separated by fitting the section of the antenna emission overlapping the Ln(III) emission with an exponential decay or with a scaled emission spectrum from the corresponding Gd(III) complexes. The quantum yields were then calculated according to (3). The given relative error on the quantum yields ($\delta\Phi = \Delta\Phi/\Phi$, where $\Delta\Phi$ is the absolute error) take into account the accuracy of the spectrometer and of the integration procedure [$\delta(I_s/I_{ref}) < 2\%$, an error of 0.59 ±0.01 on the quantum yield of the reference QS [$\delta(\Phi_{ref}) < 2\%$], an error on the ratio of the absorption factors [$\delta(f_{Aref}/f_{As}) < 5\%$, relative to the fixed absorption factor of the reference QS] and an error on the ratio of the squared refractive indexes [$\delta(n_s^2/n_{ref}^2) < 1\%, < 0.25\%$ around 1.333 for H$_2$O [5] and 1.328 for D$_2$O [6] on each individual refractive index], which sums to a total estimated relative error that should be $\delta\Phi_s < 10\%$. A limit value of 10% is thus chosen.

$$\Phi = \frac{I_s}{I_{ref}} \times \frac{f_{Aref}}{f_{As}} \times \frac{(n_s^2)^2}{(n_{ref}^2)^2} \times \Phi_{ref}$$  \(S1\)

Low temperature measurements were done in quartz capillaries (0.2 cm optical pathlength) at 77 K by immersion in a liquid N$_2$-filled quartz Dewar and with addition of glycerol (1 drop) to the solutions (9 drops) measured at room temperature.

Lifetimes were recorded 0.05 ms after pulsed excitation at the excitation maxima ($\lambda_{ex}$) of either 315 (coumarin) or 327 nm (carbostyril) by measuring the decay of the lanthanide main emission peak (i.e. Sm 600 nm, Eu 615 nm and Tb 545 nm). The increments after the initial delay were adjusted between 0.2–20 μs depending on the lifetime in order to have a good sampling of the decay. The obtained data were fitted by single and double exponential decay models in OriginPro 9 (OriginLab Corporation, Northampton, Massachusetts, USA), and the most reliable value was chosen according to the adjusted $R^2$ value and the shape of the
residuals. A relative error of 10% is typically found among a series of measurements on the same sample.

Hydration numbers ($q$) were obtained by measuring the lifetimes of the same quantity of complex in a PIPES buffered solution in H$_2$O and in D$_2$O and fitting the difference according to the model of Horrocks et al. [7], and Beeby et al [8].

The NIR emission and excitation spectra were recorded on a Horiba Jobin Yvon Fluorolog3-22 instrument (HORIBA Jobin Yvon, Edison, New Jersey, USA) and automatically corrected for wavelength dependent instrument sensitivity.

Cyclic Voltammetry

In the samples of EuL1-2d Cou Eu³⁺ (aq) is also detected in the cyclic voltammograms.

Aqueous solutions

Table S1. pH values of the solutions used in aqueous cyclic voltammetry.

| Complex                  | pH  |
|--------------------------|-----|
| EuCl₃                    | 6.53|
| EuL1a Car                | 6.47|
| EuL2a Car (Cl⁻ counterions) | 6.51|
| EuL2c Car (Cl⁻ counterions) | 6.52|
| EuL1d Cou                | 6.58|
| EuL2d Cou (Cl⁻ counterions) | 6.53|
| EuL2d Cou (OTf⁻ counterions) | 6.57|

Table S2. Cyclic voltammetry of Eu(III) complexes with OTf-counterions. [a]

| Compound                  | E₁/₂ [b] | Eₚa [b] | Eₚc [b] | ΔE [b] |
|---------------------------|----------|---------|---------|--------|
| EuL2d Cou                 | −634     | −536    | −732    | 196    |

[a] E₁/₂ is a half-wave potential, Eₚa (Eₚc) is anodic (cathodic) peak potential, ΔE is peaks separation. [b] Values are in mV vs. NHE. Measured in H₂O (LiCl 0.1 M, pH 6.57) with a sample concentration of 1 mM at a glassy C electrode using a SCE as a reference electrode and a Pt wire counter electrode with a scan rate of 100 mV/s.

Table S3. Comparison of cyclic voltammetry data for secondary and tertiary amide-linked carbostyril Eu(III) complexes. [a]

| Compound                  | E₁/₂ [b] | Eₚa [b] | Eₚc [b] | ΔE [b] |
|---------------------------|----------|---------|---------|--------|
| EuL1a Car                  | −948     | −766    | −1131   | 365    |
| EuL1b Car [c]              | −839     | −771    | −908    | 137    |
| EuL2a Car                  | −612     | −437    | −787    | 350    |
| EuL2b Car [c]              | −554     | −472    | −643    | 171    |

[a] E₁/₂ is a half-wave potential, Eₚa (Eₚc) is anodic (cathodic) peak potential, ΔE is peaks separation. [b] Values are in mV vs. NHE. Measured in H₂O (LiCl 0.1 M, pH 6.3–6.7) with a sample concentration of 1 mM at a glassy C electrode using a SCE as a reference electrode and a Pt wire counter electrode with a scan rate of 100 mV/s. [c] Data from [9].

$E_{1/2}$ is a half-wave potential, $E_{pa}$ ($E_{pc}$) is anodic (cathodic) peak potential, $\Delta E$ is peaks separation. [a] Values are in mV vs. NHE. Measured in DMF (TBAPF$_6$ 0.1 M) with a sample concentration of 1 mM at a glassy carbon electrode using a SCE as a reference electrode and a Pt wire counter electrode with a scan rate of 100 mV/s. Ferrocene was added to each sample at the end of experiment and the potentials were adjusted according to reported values [3].

| SmL2d^{Cou–F} | 0.66 | 0.074 (×1.1) | 0.014 | 0.041 |

[a] Formed by the addition of excess KF (0.1 M, 10⁴-fold excess) to a solution of SmL. [SmL] = 10 µM in 10 mM aqueous PIPES buffer solutions at pH 6.5. [b] Relative to quinine sulfate (\( \Phi = 0.59 \)) in H₂SO₄ (0.05 M) [4].

Table 31. Antenna and Ln(III)-based luminescence quantum yields of SmL–F in PIPES-buffered D₂O and changes relative to solutions in H₂O. [a]

| Complex | \( \Phi_L [%] \) [b] | \( \Phi_{Ln} [%] \) [b] | \( \Phi_{Ln,D_{2}O} \) | \( \Phi_{Ln,H_{2}O} \) |
|---------|---------------------|---------------------|-----------------|-----------------|
| SmL1a^{Car–F} | 3.6 | 0.65 | 3.4 |
| SmL2a^{Car–F} | 3.5 | 0.77 | 3.3 |
| SmL1d^{Cou–F} | 0.67 | 0.19 | 4.2 |
| SmL2d^{Cou–F} | 0.73 | 0.22 | 3.0 |

[a] Formed by the addition of excess KF (0.1 M, 10⁴-fold excess) to a solution of SmL. [SmL] = 10 µM in 10 mM PIPES buffer solutions in D₂O at pH 6.5 at nominally 10 µM concentrations. [b] Relative to quinine sulfate (\( \Phi = 0.59 \)) in H₂SO₄ (0.05 M) [4]. [c] Fold increase relative to the solution in H₂O.
Figure S67. Steady-state emission spectra of SmL1a\textsuperscript{Car} with and without added excess of KF showing relative emission intensities under similar sample absorbance. [SmL1a\textsuperscript{Car}] = 10 µM in 10 mM D\textsubscript{2}O PIPES buffer at pH 6.5, λ\textsubscript{ex} = 327 nm, front slits: 2 nm, exit slits: 1.5 nm.

Figure S68. Steady-state emission spectra of SmL2a\textsuperscript{Car} with and without added excess of KF showing relative emission intensities under similar sample absorbance. [SmL2a\textsuperscript{Car}] = 10 µM in 10 mM D\textsubscript{2}O PIPES buffer at pH 6.5, λ\textsubscript{ex} = 327 nm, front slits: 2 nm, exit slits: 1.5 nm.
Figure S69. Steady-state emission spectra of SmL1dCou with and without added excess of KF showing relative emission intensities under similar sample absorbance. \([\text{SmL1d}^{\text{cou}}] = 10 \, \mu\text{M}\) in 10 mM D\(_2\)O PIPES buffer at pH 6.5, \(\lambda_{\text{ex}} = 315\, \text{nm}\), front slits: 2 nm, exit slits: 1.5 nm.

Figure S70. Steady-state emission spectra of SmL2dCou with and without added excess of KF showing relative emission intensities under similar sample absorbance. \([\text{SmL2d}^{\text{cou}}] = 10 \, \mu\text{M}\) in 10 mM D\(_2\)O PIPES buffer at pH 6.5, \(\lambda_{\text{ex}} = 315\, \text{nm}\), front slits: 2 nm, exit slits: 1.5 nm.
Figure S71. Excitation of Eu(III) luminescence (black, $\lambda_{em} = 615$ nm), steady-state (dark gray) and time-resolved (red) emission spectra of EuL complexes at 77 K. [EuL] = 10 µM with 10% glycerol in aqueous 10 mM PIPES buffer solutions at pH 6.5 with $\lambda_{ex} = 315$ nm (EuL\textsuperscript{Cou}) and 327 nm (EuL\textsuperscript{Car}).
