ON THE IRREVERSIBLE DYNAMICS EMERGING FROM QUANTUM RESONANCES

MARTIN KÖNENBERG and MARCO MERKLI

Abstract. We consider the dynamics of quantum systems which possess stationary states as well as slowly decaying, metastable states arising from the perturbation of bound states. We give a decomposition of the propagator into a sum of a stationary part, one exponentially decaying in time and a polynomially decaying remainder. The exponential decay rates and the directions of decay in Hilbert space are determined, respectively, by complex resonance energies and by projections onto resonance states. Our approach is based on an elementary application of the Feshbach map. It is applicable to open quantum systems and to situations where spectral deformation theory fails. We derive a detailed description of the dynamics of the spin-boson model at arbitrary coupling strength.

1. Introduction and main result

1.1. General setup. Let $L_0$ be a self-adjoint operator on a Hilbert space $\mathcal{H}$ and consider

\begin{equation}
L = L_0 + \Delta I,
\end{equation}

where $\Delta \in \mathbb{R}$ is a perturbation parameter and $I$ is a self-adjoint operator, so that $L$ is self-adjoint. We assume that the spectrum of $L_0$ is absolutely continuous (possibly, but not necessarily semi-bounded) and that $L_0$ has finitely many eigenvalues $e$ with finite multiplicities $m_e$. All the eigenvalues of $L_0$ are embedded in the continuous spectrum. (Isolated eigenvalues can be included in the description using ordinary analytic perturbation theory.)

In the setting of usual (analytic) perturbation theory, an isolated eigenvalue $e$ of multiplicity $m_e$ splits, under perturbation, into a group of eigenvalues $E_{e,1}, \ldots, E_{e,\ell_e}$ ($1 \leq \ell_e \leq m_e$), in the sense that $E_{e,j}(\Delta) \rightarrow e$ as $\Delta \rightarrow 0$, for $j = 1, \ldots, \ell_e$. The sum of the multiplicities of the eigenvalues $E_{e,j}$ of $L$ equals $m_e$. On the other hand, it is well known that embedded eigenvalues can be unstable, or partially stable, under perturbation. Instability means that $L$ does not have any eigenvalues in a neighbourhood of $e$ for small $\Delta$. Partial stability means that the embedded eigenvalue $e$ of $L_0$ splits into a group of eigenvalues of $L$ whose sum of multiplicities are strictly smaller than that of $e$.

We consider the situation where $L_0$ has unstable and partially stable eigenvalues, and where the partially stable ones undergo a reduction to dimension one under perturbation. Namely, close to any eigenvalue $e$ of $L_0$, the operator $L$ either does not have any eigenvalue ($e$ unstable) or $L$ has exactly one simple eigenvalue $E_e$ close to $e$, meaning that $\lim_{\Delta \rightarrow 0} E_e = e$. It is supposed that all eigenvalues of $L$ are of this form. One may develop the arguments of this paper also
in the more general setting where close to every $e$, $L$ has several eigenvalues $E_1, \ldots, E_\ell$ which may not also not be simple. We do not do this here to keep the exposition simpler.

The dependence of $E$ on $\Delta$ is not governed by usual analytic perturbation theory, since the unperturbed $e$ is an embedded eigenvalue of $L_0$. However, some modified expressions from analytic perturbation theory of isolated eigenvalues still play a role in the present setting. Let $P_e$ be the spectral projection of $L_0$ associated to the eigenvalue $e$. If $e$ was an isolated eigenvalue of $L_0$, then the first and the second order corrections (in $\Delta$) of eigenvalues would be given, according to analytic perturbation theory \cite{22}, by the eigenvalues of $P_e IP_e$ and of $P_e IP_e^\perp (L_0 - e)^{-1} IP_e$, respectively.

We assume that

(A1) For all eigenvalues $e$ of $L_0$,
\begin{equation}
(1.2) \quad P_e IP_e = 0.
\end{equation}

For embedded $e$, the resolvent $P_e^\perp (L_0 - e)^{-1}$ does not exist as a bounded operator, so $P_e IP_e^\perp (L_0 - e)^{-1} IP_e$ is not defined, typically. Nevertheless, we can replace $e$ by $e - i \epsilon$ and consider $\epsilon$ small. This suggests that the second order eigenvalue corrections to $e$ are linked to the
level shift operator

\begin{equation}
(1.3) \quad \Lambda_e = \Lambda_e IP_e^\perp (L_0 - e) + i 0_+)^{-1} IP_e,
\end{equation}

where $i 0_+$ indicates the limit of the resolvent $(L_0 - e + i \epsilon)^{-1}$, as $\epsilon \to 0_+$. The existence of the limit is guaranteed by assumption (A2) below (take $\Delta = 0$ in the resolvent in (1.5)). The operator $\Lambda_e$ is represented by an $m_e \times m_e$ matrix.

Let $Q$ be an orthogonal projection and denote
\begin{equation}
(1.4) \quad R_z = (L - z)^{-1} \quad \text{and} \quad R_z^Q = (Q^\perp L Q^\perp - z)^{-1} \upharpoonright \text{Ran} Q^\perp.
\end{equation}

In the following, we denote by $C(\phi, \psi)$ a constant which is independent of $z$ and $\Delta$ but which may depend on $\phi, \psi \in \mathcal{H}$.

(A2) (Limiting Absorption Principle.) There is a dense set $\mathcal{D} \subset \mathcal{H}$ with $\text{Ran} IP_e \subset \mathcal{D}$ (\forall e) and there is an $\alpha > 0$ such that the following hold.

(1) Let $S_e = \{z \in \mathbb{C}_- : \text{Re} z - e \leq \alpha\}$. Here, $\mathbb{C}_-$ denotes the (open) lower complex half plane. For all $e$ and all $\phi, \psi \in \mathcal{D}$, we have
\begin{equation}
(1.5) \quad \sup_{z \in S_e} |\frac{d^k}{dz^k} \langle \phi, R_z^P \psi \rangle| \leq C(\phi, \psi) < \infty, \quad k = 0, \ldots, 3.
\end{equation}

(2) Let $S_\infty = \{z \in \mathbb{C}_- : \text{Re} z - e > \alpha \text{ for all } e\}$. For all $\phi, \psi \in \mathcal{D}$, we have
\begin{equation}
(1.6) \quad \sup_{z \in S_\infty} |\frac{d^k}{dz^k} \langle \phi, R_z \psi \rangle| \leq C(\phi, \psi) < \infty, \quad k = 0, 1.
\end{equation}

Assumption (A2)(1) implies that $P_e IR_z^P IP_e$ extends as a twice continuously differentiable function to real $z$ with $|z - e| \leq \alpha$. Moreover, the estimates (1.5) and (1.5) with $k = 0$ imply that $P_e IP_e^\perp$ and $L$ have purely absolutely continuous spectrum in the interior of $S_e$ and $S_\infty$, respectively (see e.g. \cite{23} or \cite{10}, Proposition 4.1).

(A3) The operators $\frac{d}{d\Delta} P_e IR_z^P IP_e$ is bounded, uniformly for $z \in \mathbb{C}_-$ with $|\text{Re} z - e| \leq \alpha$ and for all $|\Delta| \leq \Delta_0$. 

The Feshbach map associated to an orthogonal projection $Q$, applied to $L - z$, is defined by
\[ \mathfrak{F}(L - z; Q) = Q(L - z - LR_z^2L)Q. \]

It follows from (A1) and (A2) that
\[ \lim_{\epsilon \to 0^+} \mathfrak{F}(L - E_e + i\epsilon; P_e) \equiv \mathfrak{F}(L - E_e; P_e) = P_e(e - E_e - \Delta^2 IR_{E_e-i0+}^P)P_e. \]

Let $\psi_{E_e} = \psi_{E_e}(\Delta)$ be s.t. $L\psi_{E_e} = E_e\psi_{E_e}$. Note that $P_e\psi_{E_e} \neq 0$ for otherwise $P_e^\perp L P_e^\perp \psi_{E_e} = E_e P_e^\perp \psi_{E_e}$, which cannot hold for small $\Delta$, since $P_e^\perp L P_e^\perp$ has purely absolutely continuous spectrum in a neighbourhood of $e$ due to Condition (A2)(1). We normalize $\psi_{E_e}$ as $\|P_e\psi_{E_e}\| = 1$.

By the isospectrality property of the Feshbach map (see Appendix B, Proposition B.2), we have
\[ 0 = \mathfrak{F}(L - E_e; P_e) P_e \psi_{E_e} = (e - E_e + \Delta^2 IR_{E_e-i0+}^P)P_e \psi_{E_e}. \]

This, together with Conditions (A2)(1) and (A3), implies that $\xi_\Delta := \frac{e - E_e}{\Delta^2}$ is bounded in $\Delta$ for small $\Delta$ and that $P_e IR_{E_e-i0+}^P P_e = \Lambda_e + O(\Delta)$ for some $\xi_0 \in \mathbb{R}$ and some unit vector $P_e \psi_0$ (Bolzano-Weierstrass). Consequently, taking $\Delta \to 0$ in (1.8) along this sequence gives
\[ \Lambda_e P_e \psi_0 = \xi_0 P_e \psi_0, \]
showing that $\xi_0$ is a real eigenvalue of $\Lambda_e$. For ease of presentation, we assume the following.

(A4) (Fermi Golden Rule Condition.) The eigenvalues of all the level shift operators $\Lambda_e$ are simple. Moreover,

(1) If $e$ is an unstable eigenvalue, then all the eigenvalues $\lambda_{e,0}, \ldots, \lambda_{e,m_e-1}$ of $\Lambda_e$ have strictly positive imaginary part.

(2) If $e$ is a partially stable eigenvalue, then $\Lambda_e$ has a single real eigenvalue $\lambda_{e,0}$. All other eigenvalues $\lambda_{e,1}, \ldots, \lambda_{e,m_e-1}$ have strictly positive imaginary part.

Under condition (A4)(2), the set $\{\xi_\Delta = \frac{e - E_e}{\Delta^2}\}$ for $\Delta$ small has a unique limit point $\xi_0$ and we have
\[ \lambda_{e,0} = \xi_0. \]

Having only simple eigenvalues, $\Lambda_e$ is diagonalizable and has the spectral representation
\[ \Lambda_e = \sum_{j=0}^{m_e-1} \lambda_{e,j} P_{e,j}, \]
where $P_{e,j}$ are the (rank one) spectral projections. We introduce the notation
\[ a < b, \]
where $a$ is a complex number, a vector or a bounded operator and $b > 0$, to mean that $|a| \leq \text{const.}b$, where $|\cdot|$ is the appropriate norm and const. is a constant which does not depend on the coupling parameter $\Delta$, nor on time $t$. 
Theorem 1.1 (Resonance expansion of propagator). Denote the projection onto the eigenvalue $E_e$ of $L$ by $\Pi_{E_e}$. Let $t > 0$, $\phi, \psi \in \mathcal{D}$ s.t. $L\phi, L\psi \in \mathcal{D}$. We have

\begin{equation}
\langle \phi, e^{itL}\psi \rangle = \sum_{e \text{ partially stable}} e^{itE_e} \langle \phi, \Pi_{E_e} \psi \rangle + \sum_{j=1}^{m_e-1} e^{it(e+\Delta^2a_{e,j})} \langle \phi, \Pi'_{e,j} \psi \rangle \\
+ \sum_{e \text{ unstable}} \sum_{j=0}^{m_e-1} e^{it(e+\Delta^2a_{e,j})} \langle \phi, \Pi'_{e,j} \psi \rangle + R(t),
\end{equation}

(1.13)

where

\begin{equation}
R(t) \lesssim \frac{1}{t}.
\end{equation}

(1.14)

The exponents $a_{e,j}$ and the operators $\Pi'_{e,j}$ are close to the spectral data of the level shift operator $\Lambda_e$, (1.11):

\begin{equation}
a_{e,j} = \lambda_{e,j} + O(\Delta), \quad \Pi'_{e,j} = P_{e,j} + O(\Delta).
\end{equation}

(1.15)

Remarks. 1. For an expansion of $\langle \phi, e^{itL}\psi \rangle$ for $t > 0$, simply take the adjoint of (1.13).

2. The exponents $a_{e,j}$ are the eigenvalues of an explicit matrix. They can be calculated to all orders in $\Delta$ (see Lemma 3.1). The operators $\Pi'_{e,j}$ have also expressions calculable to all orders in $\Delta$ (see (3.8)).

3. The remainder term is small relative to the contributions of the exponentially decaying terms in (1.13) for times $t$ satisfying $e^{-\gamma \Delta^2 t} \gg 1/t$, where

\begin{equation}
\gamma = \min_{e,j} \{\text{Im}a_{e,j}\}.
\end{equation}

(1.16)

The inequality $e^{-\gamma \Delta^2 t} \geq C/t$, for some (large) $C$ is equivalent to $\frac{\ln(t) - \ln(C)}{t} \geq \gamma \Delta^2$. For small $\Delta$, it is valid for intermediate times, $t_0 < t < t_1$, with $t_0 = C + O(\gamma \Delta^2)$ and $t_1 \sim 1/(\gamma \Delta^2)$. During this time-interval, the decay of (1.13) behaves as exponential, to leading order.

1.2. History, relation to other work. The analysis of resonance phenomena has a long history and plays an important role in quantum physics [9, 21, 34, 39]. Its modern description, involving dilation analytic Hamiltonians ([1, 3]), was given in [36] and further developed in [37, 35, 19]. We refer to [18] for a textbook presentation and many more references. A time-dependent theory of quantum resonances was established in [30], inspired by [38] and further developed in [24]. In these works, a variant of the Mourre theory is used to link dynamical properties of quantum systems to spectral objects. The tools we develop in the present paper are, in spirit, related to those of [30], but the latter work cannot handle applications to open systems we have in mind (the Mourre theory is too singular in the present case). In the context of open quantum systems, the link between quantum resonances and approach of an equilibrium state has been pioneered, using complex deformation theory, in [20, 7]. The work [7] is based on a sophisticated renormalization group method initiated in [14, 5, 14]. Recently, a method based on graph expansions of the propagator rather than purely spectral considerations was given in [11]. The spectral approach has been further developed to yield a detailed description of open systems dynamics in terms of resonances in [31, 32, 33], with applications to quantum information
theory \cite{27, 29} and quantum chemistry \cite{28}. The spectral analysis and its consequences for “return to equilibrium” based on Mourre theory and positive commutators was carried out in \cite{12, 26, 17, 13}. However, these papers are limited to the study of the spectrum of the Liouville operator with the goal (typically) of showing that it has a single, simple eigenvalue at zero (and absolutely continuous spectrum otherwise). This information alone does not provide any detail about the dynamics other than ergodicity, but one is equally (sometimes mostly!) interested in information such as directions of decay and decay rates (speed of thermalization, decoherence). In the method of complex deformation, complex resonance energies are linked “automatically” to the decay rates of reduced density matrix elements \cite{32}. The same expressions describing those decay rates appear as well in Mourre theory as a consequence of the Fermi Golden Rule (see also \cite{16}), however, in the Mourre theory approach, they have not been linked to the dynamics so far – other than that their strict positivity implies ergodicity. We show in the present paper how to extract the detailed dynamical information from the Mourre theory, using the Feshbach map. This is an important issue, since spectral deformation demands much more regularity from the models one can treat, and, in some physically relevant situations, the spectral deformation technique is not applicable at all. This happens for the spin-boson model at arbitrary coupling, whose ergodicity has been shown recently in \cite{23} using Mourre theory. As an application of our method, we give a detailed expansion of the propagator of this model in the present paper.

1.3. Outline of the proof of Theorem 1.1. For $\psi \in \text{dom}(L)$, we have (\cite{15}, Corollary II 3.6)

$$e^{itL}\psi = -\frac{1}{2\pi i} \int_{\mathbb{R}-iw} e^{itz} R_z \psi \, dz,$$

where $w > 0$ is arbitrary and $R_z = (L - z)^{-1}$, see (\ref{1.4}). We write $e^{itz} = \frac{1}{it} \frac{dz}{\pi i} e^{itz}$ and integrate by parts in (\ref{1.17}) to obtain

$$e^{itL}\psi = \frac{1}{it} \frac{dz}{2\pi i} \int_{\mathbb{R}-iw} e^{itz} \frac{dz}{\pi i} R_z \psi \, dz.$$

The boundary terms in the integration by parts vanish since $R_z \psi \to 0$ as $|z| \to \infty$.

We analyze separately the contributions to the integral in (\ref{1.18}) coming from $z$ in different regions on the line of integration. Define the gap of all the clusters of resonances by

$$\delta = \min_{e,j,i} \{|\lambda_{e,i} - \lambda_{e,j}| : i \neq j\} > 0$$

and denote the eigenvalue gap of $L_0$ by

$$g = \min_{e,e'}\{|e - e'| : e \neq e'\} > 0.$$ 

Let

$$\alpha = \frac{1}{2} \min \left\{ c\delta, g, \text{Im}\lambda_{e,j} : (e,j) \text{ s.t. } \text{Im}\lambda_{e,j} > 0 \right\} > 0.$$
Here, $c$ is a constant not depending on $\Delta, w$ (its origin is explained in Lemma [3.1]). For any eigenvalue $e$ of $L_0$, set

$$G_e = \{x - iw : |x - e| \leq \alpha\}$$

and set

$$G_\infty = \{x - iw : x \in \mathbb{R}\} \cup_e G_e.$$ 

It follows from (1.18) that

$$\langle \phi, e^{itL} \psi \rangle = \sum_e J_e(t) + J_\infty(t),$$

where

$$J_\#(t) = \frac{1}{it} \frac{1}{2\pi i} \int_{G_\#} e^{itz} \langle \phi, \frac{d}{dz} R_z \psi \rangle dz.$$ 

We now apply a suitable Feshbach map to the resolvent $R_z$ in (1.25), with a projection depending on the region of integration. Let $P$ be an orthogonal projection and recall the notation (1.4). The resolvent has the representation

$$R_z = \mathcal{F}(z)^{-1} + \mathcal{B}(z) + R_z^Q,$$

where $\mathcal{F}(z) \equiv \mathcal{F}(L - z, Q)$, see (1.7), and

$$\mathcal{B}(z) = -\mathcal{F}(z)^{-1} QLR_z^Q - R_z^Q LQ \mathcal{F}(z)^{-1} + R_z^Q LQ \mathcal{F}(z)^{-1} QLR_z^Q.$$ 

We explain these relations and some properties of the Feshbach map in Appendix B. For $z \in G_e$, we choose the projection $Q$ in the Feshbach map to be $P_e$. For $z \in G_\infty$, the argument is simpler, see Section 3.3.

Let us assume that the unperturbed, partially stable eigenvalue of $L_0$ is at the origin, $e = 0$. (Otherwise see section 3.) Then $L$ has a simple eigenvalue $E \equiv E_0$ with $E \to 0$ as $\Delta \to 0$. To analyze $J_0(t)$, we write, according to (1.26),

$$J_0(t) = \frac{1}{it} \frac{1}{2\pi i} \int_{G_0} e^{itz} \left\{ \langle \phi, \frac{d}{dz} \mathcal{F}(z)^{-1} \psi \rangle + \langle \phi, \frac{d}{dz} \mathcal{B}(z) \psi \rangle + \langle \phi, \frac{d}{dz} R_z^Q \psi \rangle \right\} dz.$$ 

The Feshbach term is $\mathcal{F}(z) = -z + \Delta^2 A_z$, where $A_z = -P_0 IR_z^Q IP_0$. For $z = 0$ and $\Delta = 0$, $A_z$ is just the level shift operator $\Lambda_0$, (1.3). We show in Lemma 3.1 that $A_z$ is diagonalizable, $A_z = \sum_{j=0}^{m_e - 1} a_{0,j}(z) Q_j(z)$, and that the eigenvalues $a_{0,j}(z)$ of $A_z$ satisfy $a_{0,0}(E) = E/\Delta^2$ for all $\Delta \neq 0$ (this follows from the isospectrality property of the Feshbach map and the fact that $E$ is an eigenvalue of $L$) and $a_{0,j}(z) = \lambda_{0,j} + O(\Delta^2 + |z|)$, $j = 1, \ldots, m_e - 1$ (since $A_z$ is close to $\Lambda_0$). Then we can write

$$\frac{d}{dz} \mathcal{F}(z)^{-1} = \frac{d}{dz} \sum_{j=0}^{m_e - 1} \frac{Q_j(z)}{-z + \Delta^2 a_{0,j}(z)}.$$
We are interested in the singularities of this function as \( z \) is close to the real axis. They come from the denominator. To understand the nature of the singularities, and since \( z \mapsto Q_j(z) \) is regular, consider \( Q_j(z) \approx Q_j(0) \) for a moment. Then

\[
\frac{d}{dz} \tilde{\Phi}(z)^{-1} \approx \sum_{j=0}^{m_e-1} \frac{1 - \Delta^2 a'_{0,j}(z)}{(z - \Delta^2 a_{0,j}(z))^2} Q_j(0).
\]

(1.30)

For \( j = 0 \) we have \(-E + \Delta^2 a_{0,0}(E) = 0\) (see above) and the corresponding summand is

\[
\frac{1}{(z - E)^2} \frac{1 - \Delta^2 a'_{0,0}(z)}{(1 - \Delta^2 a'_{0,0}(E))^2} Q_0(0) \approx \frac{1}{(z - E)^2} \frac{1}{1 - \Delta^2 a'_{0,0}(E)} Q_0(0).
\]

(1.31)

By using that the projection associated to the eigenvalue \( E \) of \( L \) is given by

\[
\Pi_E = \lim_{\epsilon \to 0^+} (i\epsilon)(L - E + i\epsilon)^{-1}
\]

and decomposing the resolvent in this limit according to (1.26) with projection \( P_0 \), we identify (see (3.38))

\[
\frac{Q_0(E)}{1 - \Delta^2 a'_{0,0}(E)} = P_0 \Pi_E P_0.
\]

For \( j > 0 \) we have \( a_{0,j}(0) = \lambda_{0,j} + O(\Delta^2) \) which is in the open upper complex half plane and the corresponding summand in (1.30) is

\[
\frac{1 - \Delta^2 a'_{0,j}(z)}{(z - \Delta^2 a_{0,j}(z))^2} Q_j(0) \approx \frac{Q_j(0)}{(1 - \Delta^2 a_{0,j}(0))^2}.
\]

(1.32)

In Section 3 we make these arguments rigorous. Namely, we show that

\[
\frac{d}{dz} \tilde{\Phi}(z)^{-1} = \frac{1}{(z - E)^2} P_0 \Pi_E P_0 + \sum_{j=1}^{m_e-1} \frac{Q_j(0)}{(z - \Delta^2 a_{0,j}(0))^2} + \tilde{T}(z),
\]

(1.33)

where \( \int_{G_0} e^{itz} \tilde{T}(z) dz \ll 1 \). Now we have to multiply (1.32) by \( e^{itz} \) and integrate over \( z \in G_0 = [-\alpha, \alpha] - iw \). Having in mind a standard argument from complex analysis, we complete the path \( G_0 \) into a closed contour (a rectangle with a ‘roof’ parallel to \( G_0 \) but shifted far into the upper complex half plane). We then use the Cauchy formula for contour integrals to get

\[
\int_{G_0} \frac{e^{itz}}{(z - E)^2} dz = 2\pi i \cdot it e^{iE} + O(1/t).
\]

(1.34)

The \( O(1/t) \) term is the contribution from the parallel vertical sides of the rectangular closed integration path (see 3.21). In a similar way, we treat the sum in (1.32). Here the poles are at \( z = \Delta^2 a_{0,j}(0) \) and so

\[
\int_{G_0} \frac{e^{itz}}{(z - \Delta^2 a_{0,j}(0))^2} dz = 2\pi i \cdot it e^{i\Delta^2 a_{0,j}(0)} + O(1/t).
\]
Combining (1.32) with (1.33) and (1.34) yields

\[
\frac{1}{i\hbar} \int_{\mathcal{G}_0} e^{itz} \langle \phi, \frac{d}{dz} \tilde{\mathcal{F}}(z)^{-1} \psi \rangle dz = e^{iE} \langle \phi, P_0 \Pi_E P_0 \psi \rangle + \sum_{j=1}^{m_\text{e}-1} e^{i\Delta^2 a_{0,j}(0)} \langle \phi, Q_j(0) \psi \rangle + O(1/t).
\]

Next we deal with the second integrand in (1.28). Using again the spectral representation of \( \tilde{\mathcal{F}}(z)^{-1} \), we have from (1.27)

\[
\frac{d}{dz} \mathcal{B}(z) = \frac{d}{dz} \sum_{j=0}^{m_\text{e}-1} \frac{q_j(z)}{-z + \Delta^2 a_{0,j}(z)},
\]

where

\[
q_j(z) = -\Delta \left[ Q_j(z) P_0 I R_z^F + R_z^F P_0 Q_j(z) - \Delta R_z^F P_0 Q_j(z) P_0 I R_z^F \right].
\]

The expression (1.36) has the same structure as (1.29). We readily obtain, in analogy with (1.35),

\[
\frac{1}{i\hbar} \int_{\mathcal{G}_0} e^{itz} \langle \phi, \frac{d}{dz} \mathcal{B}(z) \psi \rangle dz = e^{itE} \langle \phi, \frac{q_0(E)}{1-\Delta^2 a_{0,0}(E)} \psi \rangle + \sum_{j=1}^{m_\text{e}-1} e^{it\Delta^2 a_{0,j}(0)} \langle \phi, q_j(0) \psi \rangle + O(|\Delta|/t).
\]

Proceeding as above, after (1.31), we identify \( P_0 \Pi_E P_0 + \frac{q_0(E)}{1-\Delta^2 a_{0,0}(E)} = \Pi_E \) (see also (3.43)). Finally, since by Assumption (A2)(1),

\[
\int_{\mathcal{G}_0} e^{itz} \langle \phi, \frac{d}{dz} R_z^F \psi \rangle dz < 1,
\]

we obtain

\[
J_0(t) = \langle \phi, \Pi_E \psi \rangle + \sum_{j=1}^{m_\text{e}-1} e^{it\Delta^2 a_{0,j}(0)} \langle \phi, \Pi_0' \psi \rangle + O(1/t),
\]

where \( \Pi_0' = Q_0(0) + O(|\Delta|) = P_{0,j} + O(|\Delta|) \). This explains the contribution of a term on the right side of (1.13) coming from a partially stable eigenvalue \( e (= 0) \). The analysis for unstable \( e \) follows using the same arguments. Finally, to deal with \( J_\infty(t) \), we write

\[
R_z \psi = (z + i)^{-2} R_z (L + i)^2 \psi - (z + i)^{-1} \psi - (z + i)^{-2} (L + i) \psi,
\]

which is valid for \( \psi \in \text{dom}(L^2) \). The negative powers of \( z \) help the convergence of the \( z \)-integral over \( \mathcal{G}_\infty \). The bound \( J_\infty(t) < 1/t \) is then easily reached using (A2)(2).

2. Application to open quantum systems

2.1. Setup. The Hilbert space is the product of a system and a reservoir part,

\[
\mathcal{H} = \mathcal{H}_S \otimes \mathcal{H}_R.
\]

The self-adjoint generator of dynamics, called Liouvillean, is of the form (1.1), where \( L_0 \), the free (non interacting) Liouvillean, is a sum of a system and a reservoir contribution,

\[
L_0 = L_S + L_R,
\]
and \( I \) is the system-reservoir interaction operator. We consider the system to be finite-dimensional and the reservoir to be an infinitely extended free Bose gas at positive temperature, as we explain now.

Let \( S \) be a quantum system with pure state space \( \mathcal{H}_S \) of dimension \( d_0 < \infty \). For instance, for a spin \( 1/2 \), \( d_0 = 2 \). Then the Hilbert space \( \mathcal{H}_S \) in (2.1) is the GNS space (Liouville space)

\[
\mathcal{H}_S = \mathcal{S}_S \otimes \mathcal{H}_S,
\]

so that \( d = \dim \mathcal{H}_S = d_0^2 \). The doubling of the pure state system Hilbert space in (2.3) allows to represent any (pure or mixed) state of \( S \) by a vector. Namely, let \( \rho \) be a density matrix on \( \mathcal{H}_S \). It has the diagonalized form \( \rho = \sum_i p_i |\psi_i\rangle \langle \psi_i| \), to which we associate the vector \( \Psi_\rho = \sum_i \sqrt{p_i} |\psi_i\rangle \otimes |\psi_i\rangle \in \mathcal{S}_S \otimes \mathcal{H}_S \) (complex conjugation in any fixed basis – we will choose the eigenbasis of the system Hamiltonian). Then \( \text{Tr}(\rho A) = \langle \Psi_\rho, (A \otimes 1_S) \Psi_\rho \rangle \) for all \( A \in \mathcal{B}(\mathcal{S}_S) \) and where \( 1_S \) is the identity in \( \mathcal{S}_S \). This is the GNS representation of the state given by \( \rho \) in (2.1). Let \( H_S = \sum_j E_j |\varphi_j\rangle \langle \varphi_j| \) be the Hamiltonian of \( S \), acting on \( \mathcal{S}_S \). The equilibrium density matrix is \( \rho_S = e^{-\beta H_S} / \text{Tr} e^{-\beta H_S} \), which is represented on \( \mathcal{H}_S \) by the vector

\[
\Omega_{S,\beta} = (\text{Tr} e^{-\beta H_S})^{-1} \sum_j e^{-\beta E_j/2} |\varphi_j\rangle \otimes |\varphi_j\rangle.
\]

The (GNS) Hilbert space of the spatially infinitely extended free Bose gas, for states normal w.r.t. the equilibrium (KMS) state, is the Fock space

\[
\mathcal{H}_R = \mathcal{F}_\beta = \bigoplus_{n \geq 0} L^2_{\text{sym}}((\mathbb{R} \times S^2)^n, (du \times d\Sigma)^n),
\]

taken over the single-particle space \( L^2(\mathbb{R} \times S^2, du \times d\Sigma) \), where \( d\Sigma \) is the uniform measure on \( S^2 \). \( \mathcal{F}_\beta \) carries a representation of the CCR algebra in which the Weyl operators are given by \( W(f_\beta) = e^{i\beta(f_\beta)} \), where \( \phi(f_\beta) = \sqrt{2}(a^*(f_\beta) + a(f_\beta)) \). Here, \( a^*(f_\beta) \) and \( a(f_\beta) \) denote creation and annihilation operators on \( \mathcal{F}_\beta \), smoothed out with the function

\[
f_{\beta}(u, \Sigma) = \sqrt{\frac{u}{1 - e^{-\beta u}}} |u|^{1/2} \left\{ \begin{array}{ll} f(u, \Sigma), & u \geq 0 \\ -f(-u, \Sigma), & u < 0 \end{array} \right. 
\]

belonging to \( L^2(\mathbb{R} \times S^2, du \times d\Sigma) \). It is easy to see that the CCR are satisfied, namely,

\[
W(f_\beta)W(g_\beta) = e^{-\frac{i}{2} \text{Im}(f_{\beta}g_{\beta})} W(f_\beta + g_\beta).
\]

The vacuum vector \( \Omega \in \mathcal{F}_\beta \) represents the infinite-volume equilibrium state of the free Bose field, determined by the formula

\[
\langle \Omega, W(f_\beta) \Omega \rangle = \exp \left\{ -\frac{1}{2} (f, \coth(\beta |k|/2) f) \right\}.
\]

The Weyl algebra is represented on \( \mathcal{F}_\beta \) as \( W(f) \mapsto W(f_\beta) \), for functions \( f \in L^2(\mathbb{R}^3) \) such that \( \langle f, \coth(\beta |k|/2) f \rangle < \infty \). We denote the von Neumann algebra of the represented Weyl operators by \( \mathcal{W}_\beta \).

The combined system-reservoir Hilbert space is then \( \mathcal{H} \), (2.1), and the von Neumann algebra of observables is

\[
\mathcal{M} = \mathcal{B}(\mathcal{S}_S) \otimes 1_S \otimes \mathcal{W}_\beta \subset \mathcal{B}(\mathcal{H}).
\]
The coupled dynamics is given by
\[
\alpha^t(A) = e^{itL}Ae^{-itL}, \quad A \in \mathfrak{M}.
\]

It is generated by the self-adjoint Liouville operator acting on \(\mathcal{H}\),
\[
L = L_0 + \Delta I
\]
\[
L_0 = L_S + L_R,
\]
\[
I = V - JVJ.
\]

Here, \(L_S = H_S \otimes 1_S - 1_S \otimes H_S\) and \(H_S\) is the system Hamiltonian acting on \(H\). \(L_R = d\Gamma(u)\) is the second quantization of multiplication by the radial variable \(u\). The interaction \(I\) in \((2.13)\) is “in standard form”, involving a self-adjoint interaction operator \(V\) acting on \(\mathcal{H}\) and the modular conjugation \(J\), which acts as
\[
J(A \otimes 1_S \otimes W(f_{\beta}(u, \Sigma)))J = 1_S \otimes A \otimes W(f_{\beta}(-u, \Sigma)),
\]
where \(A\) is the matrix obtained from \(A\) by taking entrywise complex conjugation (matrices are represented in the eigenbasis of \(H_S\)). Note that by \((2.8)\), we have \(f_{\beta}(-u, \Sigma) = -e^{-\beta u/2}f_{\beta}(u, \Sigma)\).

By the Tomita-Takesaki theorem \([8]\), conjugation by \(J\) maps the von Neumann algebra of observables \((2.9)\) into its commutant. In particular, \(V\) and \(JVJ\) commute (strongly on a suitable domain). For more detail about this well-known setup we refer to \([20, 7, \ldots]\) and references therein. We have in mind two commonly used forms for \(V\),
\[
V_1 = G \otimes 1_S \otimes \phi(h_{\beta}) + \text{h.c.} \quad \text{or} \quad V_2 = G \otimes 1_S \otimes W(h_{\beta}) + \text{h.c.},
\]
for some matrix \(G\) on \(H_S\) and where \(h_{\beta}\) is a (represented) form factor, obtained from an \(h \in L^2(\mathbb{R}^3)\) by \((2.6)\). The interaction \(V_1\) is standard. \(V_2\) comes about when considering the spin-boson system at arbitrary coupling strength \([23]\), see Section 2.2.

The vector representing the uncoupled \((\alpha^t, \beta)\)-KMS state \((\Delta = 0)\) on \(\mathfrak{M}\) is
\[
\Omega_{0,\text{KMS}} = \Omega_{S,\theta} \otimes \Omega,
\]
where \(\Omega_{S,\theta}\) is given in \((2.4)\).

In this setup of open systems, one can derive Condition (A2) from a global limiting absorption principle as follows.

**Theorem 2.1.** Let \(P_R = 1_S \otimes |\Omega\rangle\langle\Omega|\). Suppose that there is a dense set \(\mathcal{D} \subset \mathcal{H}\) with \(\text{Ran} \Gamma P_R \subset \mathcal{D}\) (\(\forall e\)), s.t. for all \(\varphi, \psi \in \mathcal{D}\),
\[
\sup_{z \in \mathbb{C} - } |\frac{d^k}{dz^k}(\varphi, R_P^z \psi)| \leq C(\varphi, \psi), \quad k = 0, \ldots, 3.
\]

Then Condition (A2) holds with \(\alpha = g/2 = \min_{e \neq e'} \{|e - e'|\}/2\).

We prove Theorem 2.1 in Appendix A (The constant \(C(\phi, \psi)\) in \((2.17)\) may differ from that in (A2)).
2.2. The spin-boson model for arbitrary coupling strength. The spin-boson Hamiltonian is

\[
H = -\frac{1}{2}\Delta \sigma_x + \frac{1}{2}\varepsilon \sigma_z + H_R + \frac{1}{2}q_0 \sigma_z \otimes \phi(h),
\]

where \(\sigma_x\) and \(\sigma_z\) are the Pauli matrices

\[
\sigma_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}
\]

and \(\Delta, \varepsilon \in \mathbb{R}\) are the ‘tunneling matrix element’ and the ‘detuning parameter’, respectively. (We use units so that \(\hbar\) takes the value one.) The reservoir Hamiltonian is \(H_R = \int_{\mathbb{R}^3} |k| a^*(k) a(k) d^3k\). The coupling constant is \(q_0 \in \mathbb{R}\). Associated to the Hamiltonian \(H\) is the Liouvillean

\[
L = L_S + L_R + q_0 I
\]

with

\[
L_S = H_S \otimes 1_{C^2} - 1_{C^2} \otimes H_S, \\
L_R = d\Gamma(u)
\]

where \(H_S = -\frac{1}{2}\Delta \sigma_x + \frac{1}{2}\varepsilon \sigma_z\), and \(I\) given in (2.13) with \(V = \frac{1}{2} \sigma_z \otimes \phi(h)\). The total Hilbert space is given by (2.1), (2.3) with \(H_S = C^2\) and (2.5).

In order to be able to analyze the spectrum of \(L\) for arbitrarily large couplings \(q_0 \in \mathbb{R}\), one applies the unitary (‘polaron’) transformation \(U\) (see [23])

\[
U = u J u J,
\]

resulting in a new Liouvillean [25, 23]

\[
\mathcal{L} = U L U^* = \mathcal{L}_0 + \Delta I,
\]

where

\[
\mathcal{L}_0 = \mathcal{L}_S + \mathcal{L}_R = \frac{i}{2}(\sigma_z \otimes 1_S - 1_S \otimes \sigma_z) + L_R
\]

and

\[
I = -\frac{1}{2}(V - J V J), \quad V = \sigma_+ \otimes 1_S \otimes W(2f_\beta) + \sigma_- \otimes 1_S \otimes W(-2f_\beta).
\]

Here, \(\sigma_+\) and \(\sigma_-\) are the raising and lowering operators and

\[
f_\beta = (-\frac{i}{2} q_0 h/u)_\beta.
\]

The non-interacting KMS state associated to \(\mathcal{L}_0\) is

\[
\Psi_{0,KMS} = \Psi_{S,\beta} \otimes \Omega, \quad \Psi_{S,\beta} = \frac{e^{-\beta \varepsilon/4} \varphi_+ \otimes \varphi_+ + e^{\beta \varepsilon/4} \varphi_- \otimes \varphi_-}{\sqrt{e^{-\beta \varepsilon/2} + e^{\beta \varepsilon/2}}}
\]

and the interacting KMS state associated to \(\mathcal{L}\) is (Araki’s perturbation theory of KMS states)

\[
\Psi_{KMS} = \frac{e^{-\beta(\mathcal{L}_0 + \Delta V)/2} \Psi_{0,KMS}}{\|e^{-\beta(\mathcal{L}_0 + \Delta V)/2} \Psi_{0,KMS}\|}.
\]
Note that the spectrum of $L_0$ consists of a purely absolutely continuous part covering all of $\mathbb{R}$, in which are embedded the eigenvalues $e = \pm \varepsilon$ (each simple) and the doubly degenerate eigenvalue $e = 0$. The following is the main result of [23]:

**Theorem 2.2** ([23]). Recall that $(\cdot )_\beta$ is defined in (2.6). Assume that $(1 + |i\partial_u|^\eta)(ih/u)_\beta \in L^2(\mathbb{R} \times S^2, du \times d\Sigma)$ for some $\eta > 2$. Then, for any $q_0 \in \mathbb{R}$, $q_0 \neq 0$, there is a constant $\Delta_0 > 0$ s.t. if $0 < |\Delta| \leq \Delta_0$, then $L$ has purely absolutely continuous spectrum covering $\mathbb{R}$ and a single, simple eigenvalue at zero. The associated eigenvector is $\Psi_{\text{KMS}}$, (2.28).

**Remarks** 1. The eigenvalues $e = \pm \varepsilon$ of $L_0$ are unstable, while $e = 0$ is partially stable. The associated (simple) eigenvalue of $L$ is $E = 0$.

2. The spectral properties of $L$ and $L_0$ are the same, as the operators are unitarily equivalent to each other.

3. The KMS state associated to $L_0$ is given by

$$\Omega_{\text{KMS}} = U^* \Psi_{\text{KMS}} = \frac{e^{-\beta(L_0 + q_0 \sigma_x \otimes 1 \xi \cdot \xi \phi(h))) / 2 \Omega_{0,\text{KMS}}}}{\|e^{-\beta(L_0 + q_0 \sigma_x \otimes 1 \xi \cdot \xi \phi(h))) / 2 \Omega_{0,\text{KMS}}\|},$$

where $L_0 = L_S(\Delta) + L_R$, see (2.30), (2.31). One shows that $\Omega_{0,\text{KMS}}$ is in the domain of $e^{-\beta(L_0 + q_0 \sigma_x \otimes 1 \xi \cdot \xi \phi(h))) / 2}$ for any $q_0$, $\Delta \in \mathbb{R}$ (see e.g. [14], [7], [8]).

We now verify assumptions (A1)-(A4) for the spin-boson system, i.e., for the operator $L$, (2.23). The eigenprojections of $L_0$ are given, for $e \in \text{spec}(L_S)$, by

$$P_e = 1[L_S = e] \otimes |\Omega \rangle \langle \Omega|.$$ 

Since $1[L_S = e](\sigma_\pm \otimes 1)1[L_S = e] = 0 = 1[L_S = e](1_\mathbb{S} \otimes \sigma_\pm)1[L_S = e]$, condition (A1) holds.

To verify the limiting absorption principle (A2), let $N = d\Gamma(1)$ be the number operator on Fock space (2.5) and put $\tilde{N} = P_R^1 N$. Let $A = d\Gamma(i\partial_u)$ and put $\tilde{A} = P_R^1 A$. For $\alpha, \nu \geq 0$, define the norms

$$\|\xi\|_{\alpha, \nu} = \|\tilde{N}^{\nu/2}(1 + \tilde{A}^2)^{\alpha/2} \xi\|.$$

We have the following regularity properties of the resolvent $R_{z_\beta}^{P_R}$.

**Theorem 2.3.** Let $\mu \geq 1$ and suppose that $\partial_u f_{\beta} \in L^2(\mathbb{R} \times S^2, du \times d\Sigma)$, for $j = 0, \ldots, 2\mu + 1$. We have

$$\sup_{z \in \mathbb{C}} |\frac{d^{\mu-1}}{dz^{\mu-1}}(\phi, R_{z_\beta}^{P_R}\psi)| \prec \|\phi\|_{\mu, 2\mu} \|\psi\|_{\mu, 2\mu}$$

and

$$\sup_{z \in \mathbb{C}} |\frac{d^j}{dz^j}(\phi, R_{z_\beta}^{P_R}\psi)| \prec \|\phi\|_{3, 1} \|\psi\|_{3, 1}.$$ 

We give a proof of Theorem 2.3 in Appendix A. The bound (2.31) with $\mu = 4$ implies (2.17), with the dense set

$$\mathcal{D} = \{\psi : \|\psi\|_{4, 8} < \infty\}.$$ 

To see that $\text{Ran} IP_R \subset \mathcal{D}$, it suffices to check that

$$\|N^4(1 + A^4)W(2f_{\beta})\Omega\| < \infty.$$
It is not hard to use the relation
\begin{equation}
\langle d \Gamma(D), W(f) \rangle = W(f)(\phi(iDf) + \frac{1}{2}(f, Df))
\end{equation}
(where \( \phi \) is the field operator, see the proof of Lemma 3.1 in [23] for technical details) for \( D = -i \partial_t \) and \( D = 1 \) to see that (2.34) holds provided \( \partial_t^0 f_\beta \in L^2(\mathbb{R} \times S^2), j = 0, \ldots, 4 \). Therefore, Theorem 2.3 combined with this last observation shows that the assumptions of Theorem 2.1 are satisfied. Thus, by the latter theorem, assumption (A2) holds.

Next, assumption (A3) is shown to hold in Theorem A.1, (A.2). Namely, the regularity in \( \Delta \) of \( \frac{1}{i\Delta^2} P_x IR_{x_0}^m IP_e \) is derived from that of \( \frac{1}{i\Delta^2} P_x IR_{x_0}^m IP_e \), given in Theorem 2.3 (2.32).

The Fermi Golden Rule Assumption (A4) is verified by examining the level shift operators \( \Lambda_0, \Lambda_{\pm \varepsilon} \). \( \Lambda_0 \) is two-dimensional, given by (see [23], Proposition 3.5)
\begin{equation}
\Lambda_0 = i\tau^{-1} P_{S,\beta}^\perp
\end{equation}
where \( P_{S,\beta}^\perp \) is the complement of \( P_{S,\beta} = |\Omega_{S,\beta}\rangle \langle \Omega_{S,\beta}| \) in \( \text{Ran} \mathcal{L}_S = 0 \) and where \( \Omega_{S,\beta} \propto e^{-\beta t/4} \varphi_+ \otimes \varphi_++e^{\beta t/4} \varphi_- \otimes \varphi_- \) (see (2.4) and (2.24)). Also,
\begin{equation}
\tau^{-1} = \int_0^\infty dt \cos(\varepsilon t) \cos \left[ \frac{g_0^2}{\pi} Q_1(t) \right] e^{-\frac{\varepsilon^2}{4} Q_2(t)}
\end{equation}
with
\[ Q_1(t) = \int_0^\infty d\omega \frac{J(\omega)}{\omega^2} \sin(\omega t) \quad \text{and} \quad Q_2(t) = \int_0^\infty d\omega \frac{J(\omega)(1 - \cos(\omega t))}{\omega^2} \coth(\beta \omega/2). \]
Here, \( J(\omega) \) is the spectral density of the reservoir, defined by
\begin{equation}
J(\omega) = \frac{\pi}{2} \omega^2 \int_{\mathbb{R}^2} |h(\omega, \Sigma)|^2 d\Sigma, \quad \omega \geq 0,
\end{equation}
the integral being taken over the angular part in \( \mathbb{R}^3 \). The function \( h \) is the form factor in the interaction (2.18). Relation (2.36) gives
\begin{equation}
\lambda_{0,0} = 0 \quad \text{and} \quad \lambda_{0,1} = i\tau^{-1}.
\end{equation}
Hence assumption (A4)(2) holds. The resonances \( \lambda_{\pm \varepsilon,0} \) are the eigenvalues of the one-dimensional level shift operators \( \Lambda_{\pm \varepsilon} \), which are easily calculated to be
\begin{equation}
\lambda_{\pm \varepsilon,0} = \pm x + \frac{1}{2} i\tau^{-1},
\end{equation}
where \( \pm x \) is the real part. Assumption (A4)(1) thus holds.

Set \( \varphi_+ = \varphi_+ \otimes \varphi_- \) etc. and
\[
\begin{align*}
X_0 &= W(f_\beta) JW(f_\beta) \Omega, & X_0^* &= W(f_\beta)^* JW(f_\beta)^* \Omega, \\
X_+ &= W(f_\beta)^* JW(f_\beta) \Omega, & X_- &= JX_+ = W(f_\beta) JW(f_\beta)^* \Omega.
\end{align*}
\]
The dynamics of the spin-boson system at arbitrary coupling is then explicitly given as follows.

\footnote{The spectral density is related to the Fourier transform of the reservoir correlation function \( C(t) = \omega_{R,\beta} e^{itH_R} \varphi(h) e^{-itH_R} \varphi(h) \) by \( J(\omega) = \sqrt{\pi/2} \tanh(\beta \omega/2) |\tilde{C}(\omega) + \tilde{C}(-\omega)| \). Of course, it is assumed here, as it is in [23], that the integral in (2.37) does not vanish, so that \( \tau < \infty \) is a finite relaxation time.}
Corollary 2.4 (Dynamics of the spin-boson system at arbitrary coupling strength). Suppose that \( u f_\beta, \varphi^j \) are in \( L^2 (\mathbb{R} \times S^{2}) \) for \( j = 0, \ldots, 4 \). For any \( q_0 \in \mathbb{R} \) there is a \( \Delta_0 > 0 \) s.t. if \( 0 < |\Delta| < \Delta_0 \) then the following holds.

Denote by \( \Pi_0 = |\Omega_{\text{KMS}}\rangle \langle \Omega_{\text{KMS}}| \) the projection onto the coupled KMS state, \((2.29)\). Let \( \phi, \psi \in \text{dom}(L_R) \cap \text{dom}(N^{17/2} + 1)(A^4 + 1) \). We have for all \( t > 0 \)

\[
(2.41) \quad \langle \phi, e^{itL} \psi \rangle = \langle \phi, \Pi_0 \psi \rangle + e^{i\alpha f_\beta} \langle \phi, \Pi'_0 \psi \rangle + e^{i(\varepsilon + \Delta^2 \varepsilon)} \langle \phi, \Pi'_{\varepsilon} \psi \rangle + R(t),
\]

where \( R(t) \sim \frac{1}{t} \) and

\[
a_0 = \imath \tau^{-1} + O(\Delta), \quad a_{\pm \varepsilon} = \pm \tau^{-1} + O(\Delta),
\]

\[
\Pi'_0 = (e^{\beta \varepsilon / 2} + e^{-\beta \varepsilon / 2})^{-1} (e^{\beta \varepsilon / 2} |\varphi_{++}\rangle \langle \varphi_{++}| \otimes |X\rangle \langle X| - |\varphi_{++}\rangle \langle \varphi_{++]| \otimes |X\rangle \langle X|) + O(\Delta),
\]

\[
(2.42) \quad -|\varphi_{--}\rangle \langle \varphi_{--}| \otimes |X\rangle \langle X| + e^{-\beta \varepsilon / 2} |\varphi_{--}\rangle \langle \varphi_{--}| \otimes |X\rangle \langle X|) + O(\Delta),
\]

\[
(2.43) \quad \Pi'_\varepsilon = |\varphi_{+-}\rangle \langle \varphi_{+-}| \otimes |X\rangle \langle X| + O(\Delta),
\]

\[
(2.44) \quad \Pi'_{-\varepsilon} = |\varphi_{-+}\rangle \langle \varphi_{-+}| \otimes |X\rangle \langle X| + O(\Delta).
\]

Note that the dynamics in Corollary 2.4 is expressed with respect to the original Liouville operator \( L \) (not the unitarily equivalent \( L \)).

Proof of Corollary 2.4: We have \( \langle \phi, e^{itL} \psi \rangle = \langle U \phi, e^{itL} U \psi \rangle \). Theorem 1.1 gives the resonance expansion for \( \langle U \phi, e^{itL} U \psi \rangle \) provided \( U \phi, U \psi \in D \) s.t. \( L U \phi, L U \psi \in D \), where \( D \) is the set of vectors with finite norm \( \| \cdot \|_{4,5} \). One can easily show the bound

\[
\| U \psi \|_{2\alpha, \nu} \ll \| \psi \|_{2\alpha, \nu}.
\]

We conclude from \((2.45)\) that if \( \psi \in \text{dom}(N^{\nu+1/2} + 1)(A^{2\alpha} + 1) \) for some \( \nu \geq 1/2 \) and \( \alpha \geq 0 \), and if \( (i\partial)^j f_\beta \) are in \( L^2 (\mathbb{R} \times S^2) \) for \( j = 0, \ldots, 2\alpha \), then \( \| U \psi \|_{2\alpha, \nu} < \infty \).

We infer that if \( \psi \in \text{dom}(L_R) \cap \text{dom}(N^{17/2} + 1)(A^4 + 1) \), then \( U \psi \in D \) and \( L U \psi \in D \). (To see the latter inclusion, we use \((2.35)\) with \( D = u \) and proceed as in \((2.35)\).)

The operators \( \Pi'_0 \) and \( \Pi'_{\pm \varepsilon} \) are given by

\[
(2.45) \quad \Pi'_0 = U^* P^\perp_{S,\beta} P_R U + O(\Delta), \quad \Pi'_{\pm \varepsilon} = U^* P_{\pm \varepsilon} U + O(\Delta),
\]

where \( P_{\pm \varepsilon} \) are the eigenprojections of \( L_0 \) associated to the eigenvalues \( \pm \varepsilon \), \( P^\perp_{S,\beta} \) is defined after \((2.36)\) and \( P_R = 1_S \otimes |\Omega\rangle \langle \Omega| \). It is easy to calculate \( U \varphi_{++} \otimes \Omega = \varphi_{++} \otimes W(f_\beta)^* J W(f_\beta) J \Omega \), which shows \((2.43)\). Similarly one obtains \((2.44)\). For \((2.42)\), we first calculate

\[
P^\perp_{S,\beta} = (e^{\beta \varepsilon / 2} + e^{-\beta \varepsilon / 2})^{-1} (e^{\beta \varepsilon / 2} |\varphi_{++}\rangle \langle \varphi_{++}| - |\varphi_{++}\rangle \langle \varphi_{++]| - |\varphi_{--}\rangle \langle \varphi_{--}| + e^{-\beta \varepsilon / 2} |\varphi_{--}\rangle \langle \varphi_{--}|).
\]

Then we use \((2.35)\) to arrive at \((2.42)\). This completes the proof of Corollary 2.4.\[\square\]

Being a KMS state, \( \Omega_{\text{KMS}} \) given in \((2.29)\) is separating for \( \mathfrak{M} \), which means that \( \mathfrak{M}^* \Omega_{\text{KMS}} \) is dense in \( \mathcal{H} \), where \( \mathfrak{M} \) is the commutant of \( \mathfrak{M} \), see \([8]\). Any (normal) state \( \omega \) on \( \mathfrak{M} \) is given by a normalized vector \( \Psi \in \mathcal{H} \) via \( \omega(A) = \langle \Psi, A \Psi \rangle \). We introduce the dense set

\[
(2.46) \quad \mathcal{D}_0 = \text{dom}(L_R) \cap \text{dom}(N^{17/2} + 1)(A^4 + 1).
\]
The set of states $\omega$ arising from vectors in 
\[ (2.47) \quad \{ \Psi \in \mathcal{H} : \| \Psi \| = 1, \Psi = B\Omega_{\text{KMS}} \text{ for some } B \in \mathcal{M}, \text{s.t. } B^*\Psi \in \mathcal{D}_0 \} \]
is dense (in the norm of states on $\mathcal{M}$). We call it the set of regular states, $\mathcal{S}_{\text{reg}}$. We also introduce the regular observables, 
\[ (2.48) \quad \mathcal{M}_{\text{reg}} = \{ A \in \mathcal{M} : A\Omega_{\text{KMS}} \in \mathcal{D}_0 \}. \]
Let us denote the coupled equilibrium state by 
\[ (2.49) \quad \omega_{\text{KMS}}(A) = \langle \Omega_{\text{KMS}}, A\Omega_{\text{KMS}} \rangle. \]

**Corollary 2.5** (Return to equilibrium). For any $\omega_0 \in \mathcal{S}_{\text{reg}}$, $A \in \mathcal{M}_{\text{reg}}, t \geq 0$, we have 
\[ (2.50) \quad |\omega_0(\alpha^t(A)) - \omega_{\text{KMS}}(A)| \leq C_{A,\omega_0} \left[ e^{-\Delta^2 t/2t} + 1/t \right]. \]
The constant $C_{A,\omega_0}$ depends on the initial state $\omega_0$ and the observable $A$, but not on $t, \Delta$.

One readily verifies that all states of the form $\omega_s \otimes \omega_\mathcal{R}$, where $\omega_s$ is arbitrary and $\omega_\mathcal{R}$ is the reservoir equilibrium, belong to $\mathcal{S}_{\text{reg}}$. Moreover, all observables on the system alone belong to $\mathcal{M}_{\text{reg}}$, since $\Omega_{\text{KMS}} \in \mathcal{D}_0$.

**Proof of Corollary 2.5** Let $\Psi = B\Omega_{\text{KMS}}, B \in \mathcal{M}'$, be the vector representing $\omega_0$. Since $B$ commutes with $\alpha^t(A)$ and $\Omega_{\text{KMS}}$ is in the kernel of $L$, we have $\alpha^t(A)\Psi = B\alpha^t(A)\Omega_{\text{KMS}} = B e^{itL} A\Omega_{\text{KMS}}$. Thus,
\[ (2.51) \quad \omega_0(\alpha^t(A)) = \langle \Psi, e^{itL} A e^{-itL} \rangle = \langle B^*\Psi, e^{itL} A\Omega_{\text{KMS}} \rangle. \]
Now we apply (2.41) and, using that $\Pi_0 = |\Omega_{\text{KMS}}\rangle\langle\Omega_{\text{KMS}}|$, obtain directly (2.50). \qed

3. **Proof of Theorem 1.1**

For $z \in \mathbb{C}_-$, $|\text{Re}z - e| \leq \alpha$ we define the operator
\[ (3.1) \quad A_z = -P_e IR^e_z IP_e. \]
As $z \to e$ and $\Delta \to 0$, $A_z$ approaches the level shift operator $A_e$. More precisely, we have the following result, in which $\delta$ is, recall, given by (1.19).

**Lemma 3.1.** There is a constant $c$ such that if $|\Delta|$, $|\text{Re}z - e| < c\delta$, and $z \in \mathbb{C}_-$, then
1. All eigenvalues of $A_z$ are distinct. Call them $a_{e,j} = a_{e,j}(z), j = 0, \ldots, m_e - 1$. Each $a_{e,j}$ satisfies $|\lambda_{e,j} - a_{e,j}| < \delta/2$ for exactly one eigenvalue $\lambda_{e,j}$ of $A_e$.
2. The eigenvalues $a_{e,j}(z)$ of $A_z$, and the associated Riesz projections $Q_j(z)$ are analytic in $z \in \mathbb{C}_-$, $|\text{Re}z - e| < c\delta$ and continuous as $\text{Im}z \to 0_-$. They satisfy the bounds $\frac{d^k}{dz^k}a_{e,j}(z), \frac{d^k}{dz^k}Q_j(z) < 1$ for $k = 0, \ldots, 3$, uniformly for $|\text{Re}z - e| < c\delta$ and $\text{Im}z \leq 0$.

The simplicity of the spectrum implies the spectral representation
\[ (3.2) \quad A_z = \sum_{j=0}^{m_e-1} a_{e,j}(z)Q_j(z). \]
Proof of Lemma 3.1. When necessary, we display the $\Delta$-dependence of $A_z$ by $A_z(\Delta)$. (Here, $A_z$ for $x \in \mathbb{R}$ is understood as the limit of $A_z$, as $z \to x$, $z \in \mathbb{C}_-$. We have $A_e(0) = \Lambda_e$ and, by assumption (A3),
\begin{equation}
\|A_e - A_z(\Delta)\| \lesssim |\Delta| + |z - e|.
\end{equation}
Assumption (A4) implies that
\begin{equation}
\|(A_e - \zeta)^{-1}\| \lesssim \frac{1}{\text{dist}(\zeta, \text{spec}(A_e))}.
\end{equation}
Using the standard Neumann series for resolvents, together with the estimates (3.3) and (3.4), yields
\begin{equation}
(A_z(\Delta) - \zeta)^{-1} = (A_e - \zeta)^{-1} + O\left(\frac{|\Delta| + |z - e|}{\text{dist}(\zeta, \text{spec}(A_e))^2}\right),
\end{equation}
provided $|\Delta|, |z - e| < c_0 \text{dist}(\zeta, \text{spec}(A_e))$, for some constant $c_0$ independent of $\Delta, z$. Let $C_j$ be the circle centered at $\lambda_{e,j}$ with radius $\delta/2$ and define
\begin{equation}
Q_j(\Delta, z) = \frac{-1}{2\pi i} \oint_{C_j} (A_z(\Delta) - \zeta)^{-1} d\zeta.
\end{equation}
Note that $Q_j(0, e)$ is the Riesz eigenprojection of $A_e$ associated to the eigenvalue $\lambda_{e,j}$. Using (3.5) and (3.6) we obtain that $\|Q_j(\Delta, z) - Q_j(0, e)\| < 1$, provided $|\Delta|, |z - e| < c_0 \delta/2$ and $|\Delta| + |z - e| < c_1 \delta^2/4$, for some $c_1$ independent of $\Delta, z$. This proves point 1. of Lemma 3.1.

Next,
\begin{equation}
Q'_j = \frac{\partial}{\partial z} Q_j = \frac{1}{2\pi i} \oint_{C_j} (A_z(\Delta) - \zeta)^{-1} A'_z(\Delta)(A_z(\Delta) - \zeta)^{-1} d\zeta \lesssim 1.
\end{equation}
Since $a_{e,j}(z) = \text{Tr}A_zQ_j(z)$ we get $a'_{e,j}(z) = \text{Tr}(A'_zQ_j(z) + A_zQ'_j(z)) < 1$. The statements about the higher derivatives follow in the same manner. This shows point 2 and completes the proof of Lemma 3.1.

3.1. Estimates for $z$ in a vicinity of a partially stable eigenvalue $e$. We introduce the operators
\begin{equation}
\wt{Q}_j = -Q_j(e)P_eIR_{e-i0+} - R_{e-i0+}P_eQ_j(e) + \Delta R_{e-i0+}P_eQ_j(e)P_eIR_{e-i0+}, \quad j \geq 1,
\end{equation}
where $Q_j(e)$ is determined by (3.1) and $R_{e-i0+}$ is the limit of $R^e_z = (\wt{L} - z)^{-1}$ as $z$ approaches $e$ through the lower half plane. Note that $Q_j(e) = P_{e,j} + O(|\Delta|)$, see also (1.11).

Proposition 3.2. Let $\Pi_{E_e}$ be the orthogonal projection associated to the eigenvalue $E_e$ of $L$. We have, for $\phi, \psi \in \mathcal{D}$,
\begin{equation}
J_e(t) = e^{itE_e}\langle \phi, \Pi_{E_e}\psi \rangle + \sum_{j=1}^{m_e-1} e^{it(e + \Delta^2 a_{e,j}(e))} \langle \phi, (Q_j(e) + \Delta \wt{Q}_j)\psi \rangle + R_e(t)
\end{equation}
where (recall that \( w > 0 \) is the arbitrary parameter in (1.18))
\[
|R_e(t)| \leq C \frac{1 + e^{wt}/t}{t},
\]
for a constant \( C \) independent of \( \Delta, t, w, \) and where
\[
a_{e,j}(e) = \lambda_{e,j} + O(|\Delta|), \quad Q_j(e) = P_{e,j} + O(|\Delta|).
\]

**Proof of Proposition 3.2.** We apply the Feshbach map with projection \( P_e \) (having rank \( m_e \)),
\[
\mathcal{F}(z) \equiv \mathcal{F}(L - z; P_e) = e - z + \Delta^2 A_z,
\]
where \( A_z \) is given in (3.11). Due to Condition (A2), \( z \mapsto A_z \) is analytic for \( z \in \mathbb{C}_-, |z - e| < \alpha, \) and its \( z \)-derivatives up to degree 3 stay bounded as \( \text{Im} z \to 0_- \). According to the decomposition (1.26), we have
\[
\int e^{itz} \langle \phi, \frac{d}{dz} R_z \psi \rangle dz = \int e^{itz} \left[ \langle \phi, \frac{d}{dz} \mathcal{F}(z)^{-1} \psi \rangle + \langle \phi, \frac{d}{dz} \mathcal{B}(z) \psi \rangle + \langle \phi, \frac{d}{dz} P_z P \psi \rangle \right] dz,
\]
where
\[
\mathcal{B}(z) = -\Delta \mathcal{F}(z)^{-1} P_z IR_z^P - \Delta R_z^P IP_z \mathcal{F}(z)^{-1} + \Delta^2 R_z^P IP_z \mathcal{F}(z)^{-1} P_z IR_z^P.
\]
To examine \( \mathcal{F}(z)^{-1} \), we use the spectral representation of the operator \( A_z \).

### 3.1.1. The contribution to (3.12) from \( \frac{d}{dz} \mathcal{F}(z)^{-1} \). In this subsection, we will simply write
\[
a_j \equiv a_{e,j}, \quad 0 \leq j \leq m_e - 1,
\]
to ease the notation. Due to (3.11) and Lemma 3.1,
\[
\mathcal{F}(z)^{-1} = \sum_{j=0}^{m_e-1} \frac{1}{e - z + \Delta^2 a_j} Q_j.
\]

We analyze the first term on the right side of (3.12), using that
\[
\frac{d}{dz} \mathcal{F}(z)^{-1} = \sum_{j=0}^{m_e-1} T_j, \quad \text{where} \quad T_j = \frac{1 - \Delta^2 a_j'}{(z - e - \Delta^2 a_j)^2} Q_j + \frac{1}{e - z + \Delta^2 a_j} Q_j'.
\]

We examine the singularities of \( T_j \) in \( z \). By the isospectrality of the Feshbach map, we know that \( e - E_e + \Delta^2 A_{E_e} \) has an eigenvalue zero (see also (1.8)). Therefore, \( e - E_e + \Delta^2 a_0(E_e) = 0 \). Also, \( a_j(z) = \lambda_{e,j} + O(|\Delta| + |z - e|) \) for \( j = 1, \ldots, m_e - 1 \). Consider first \( T_0 \). We have
\[
z - e - \Delta^2 a_0(z) = z - e - \Delta^2 a_0(E_e) + \Delta^2 (a_0(E_e) - a_0(z)) = z - E_e + \Delta^2 (a_0(E_e) - a_0(z))
\]
and so
\[
\frac{1 - \Delta^2 a_0'}{(z - e - \Delta^2 a_0)^2} = \frac{1}{(z - E_e)^2} \frac{1 - \Delta^2 a_0(z)}{[1 - \Delta^2 (a_0(z) - a_0(E_e))]/(z - E_e)^2}
\]
\[
= \frac{1}{h(z)} + \frac{1}{(z - E_e)^2}.
\]
where

\begin{equation}
(3.17) \quad h(z) = \frac{1 - \Delta^2 a_0(z)}{[1 - \Delta^2(a_0(z) - a_0(E_e))/(z - E_e)]^2} - \frac{1 - \Delta^2 a_0(E_e)}{[1 - \Delta^2 a'_0(E_e)]^2} = O(\Delta^2 |z - E_e|^2).
\end{equation}

To arrive at (3.17), we expand \( h(z) \) around a point \( z_0 \in \mathbb{C}_- \) which is very close to \( E_e \),

\[ h(z) = h(z_0) + (z - z_0)h'(z_0) + \int_{[z_0,z]} ds \int_{[s,z_0]} ds'h''(s'). \]

The integrals are over paths (straight lines) in the lower complex plane. Then, sending \( z_0 \to E_e \), using that \( h(E_e) = h'(E_e) = 0 \) and controlling the double integral with the third derivative of \( h \), we arrive at (3.17). In this argument, we assume the derivatives up to order three to have a continuous extension as \( \text{Im} z \to 0_- \).

Thus

\begin{equation}
(3.18) \quad T_0 = \frac{1}{(z - E_e)^2} \frac{Q_0(E_e)}{1 - \Delta^2 a'_0(E_e)} + \frac{1}{1 - \Delta^2 a'_0(E_e)} \frac{[Q_0(z) - Q_0(E_e)]/(z - E_e)}{Q_0'(z)} - \frac{1}{z - E_e} \frac{Q'_0(z)}{1 - \Delta^2 [a_0(z) - a_0(E_e)]/(z - E_e)} + O(\Delta^2).
\end{equation}

An expansion of the sum of the second and third term on the right side of (3.18) shows that this term is \( O(1) \) uniformly in \( z \in \mathcal{G}_e \), giving the bound

\begin{equation}
(3.19) \quad T_0 = \frac{1}{(z - E_e)^2} \frac{Q_0(E_e)}{1 - \Delta^2 a'_0(E_e)} + O(1 + \Delta^2).
\end{equation}

Therefore,

\begin{equation}
(3.20) \quad \int_{\mathcal{G}_e} e^{itz} \langle \phi, T_0 \psi \rangle = \frac{\langle \phi, Q_0(E_e) \psi \rangle}{1 - \Delta^2 a'_0(E_e)} \int_{\mathcal{G}_e} \frac{e^{itz}}{(z - E_e)^2} dz + O(1).
\end{equation}

The remaining integral on the right side is estimated using the standard Cauchy formula from complex analysis. Namely, we complete \( \mathcal{G}_e \) into a rectangular closed path, adding the vertical pieces \( \mathcal{C}_\pm = \{ e \pm \alpha + iy : y \in [-w, R] \} \) and the horizontal roof \( \{ x + iR : e - \alpha \leq x \leq e + \alpha \} \). Then we obtain from the Cauchy integral formula of basic complex analysis, upon taking \( R \to \infty \), that

\begin{equation}
(3.21) \quad \int_{\mathcal{G}_e} \frac{e^{itz}}{(z - E_e)^2} dz = 2\pi i(e^{itz})'_{z=E_e} + O(e^{wt}/t) = it 2\pi i e^{itE_e} + O(e^{wt}/t).
\end{equation}

The remainder term comes from the integrals along the two vertical pieces of the path, which are bounded above by \( \int_{-w}^\infty e^{-yt} dy \). Note that \( w > 0 \) is arbitrary (see (1.17)) and we will take \( w \to 0 \) which will make the remainder in (3.21) to be \( O(1/t) \). Combining (3.20) and (3.21) yields

\begin{equation}
(3.22) \quad \frac{1}{it} \frac{1}{2\pi i} \int_{\mathcal{G}_e} e^{itz} \langle \phi, T_0 \psi \rangle dz = e^{itE_e} \frac{\langle \phi, Q_0(E_e) \psi \rangle}{1 - \Delta^2 a'_0(E_e)} + O(1/t + e^{wt}/t^2).
\end{equation}
Next, we analyze $T_j$ in (3.15), for $j \geq 1$. Recall that $a_j(e)|_{\Delta_0} = \lambda_{e,j}$ are the eigenvalues with strictly positive imaginary part of the level shift operator $\Lambda_e$. The integrands behave in a different way now, since $\text{Im}a_j(e) > 0$ (while before, $a_0(E_e) = 0$). The following bound is useful, 

\[
|z - e - \Delta^2a_j(z)| = |z - e - \Delta^2\lambda_{e,j} - \Delta^2(a_j(e) - \lambda_{e,j}) - \Delta^2(a_j(z) - a_j(e))| \\
\geq |z - e - \Delta^2\lambda_{e,j}| - c_1\Delta^2(|\Delta| + |z - e|) \\
\geq \frac{1}{2}|z - e - \Delta^2\lambda_{e,j}|, 
\]

(3.23) provided that $|\Delta|, |z - e| \leq c_2\text{Im}\lambda_{e,j}$, where $c_1$ and $c_2 = 1/(2c_1)$ are independent of $\Delta$ and $z$. To arrive at the last inequality, (3.23), we proceed as follows: the inequality is equivalent to

\[
|\Delta|, |z - e| \leq c_2\text{Im}\lambda_{e,j}. 
\]

Now $|z - e - \Delta^2\lambda_{e,j}| \geq |\text{Im}z - \Delta^2\text{Im}\lambda_{e,j}| \geq \Delta^2\text{Im}\lambda_{e,j}$, since $\text{Im}z < 0$ and $\text{Im}\lambda_{e,j} > 0$.

We have 

\[
T_j = \frac{Q_j(e)}{(z - e - \Delta^2a_j(e))^2} - \frac{\Delta^2a_j'(z)Q_j(z)}{(z - e - \Delta^2a_j(z))^2} + R_j + S_j, 
\]

(3.24) where

\[
R_j = \frac{1}{z - e - \Delta^2a_j(z)} \left[ \frac{z - e}{z - e - \Delta^2a_j(z)} \frac{Q_j(z) - Q_j(e)}{z - e} - Q_j'(z) \right] \\
= \frac{1}{z - e - \Delta^2a_j(z)} \left[ \frac{Q_j(z) - Q_j(e)}{z - e} - Q_j'(z) + \frac{\Delta^2a_j(z)}{z - e - \Delta^2a_j(z)} \frac{Q_j(z) - Q_j(e)}{z - e} \right] 
\]

(3.25) and 

\[
S_j = \frac{-2\Delta^2(z - e)(a_j(e) - a_j(z)) + \Delta^4a_j(e)^2 - a_j(z)^2}{[z - e - \Delta^2a_j(z)]^2(z - e - \Delta^2a_j(e)^2)} Q_j(0) = O \left( \frac{\Delta^2|z - e|^2 + \Delta^4|z - e|}{|z - e - \Delta^2\lambda_{e,j}|^4} \right). 
\]

(3.26) To arrive at the estimates (3.25) and (3.26) we have used (3.23). Similarly, the second term on the right side of (3.24) is $O(\Delta^2/|z - e - \Delta^2\lambda_{e,j}|^2)$ and so we obtain

\[
T_j = \frac{Q_j(e)}{(z - e - \Delta^2a_j(e))^2} + \tilde{T}_j, 
\]

(3.27) with 

\[
\|\tilde{T}_j\| \ll \frac{|z - e|}{|z - e - \Delta^2\lambda_{e,j}|^2} + \frac{\Delta^2}{|z - e - \Delta^2\lambda_{e,j}|^2} + \frac{\Delta^2|z - e|^2 + \Delta^4|z - e|}{|z - e - \Delta^2\lambda_{e,j}|^4}. 
\]

(3.28) Note that, with $\lambda_{e,j} = \xi_j + i\eta_j$ and $w, \eta_j > 0$, we have

\[
\frac{|z - e|}{|z - e - \Delta^2\lambda_{e,j}|} \leq 1 + \frac{\Delta^2|\lambda_{e,j}|}{|z - e - \Delta^2\lambda_{e,j}|} \leq 1 + \frac{|\lambda_{e,j}|}{\eta_j} < 1, 
\]

so 

\[
\int_{\mathbb{C}} \frac{|z - e|}{|z - e - \Delta^2\lambda_{e,j}|} dx < 1. 
\]

(3.29)
Also,

\[
\int_{\mathcal{G}_e} \frac{\Delta^2}{|z - e - \Delta^2 \lambda_{e,j}|^2} \, dx \leq 2 \int_0^{a+\Delta^2|\xi_j|} \frac{\Delta^2}{x^2 + \Delta^2 \eta_j^2} \, dx \leq 2 \int_0^\infty \frac{dy}{y^2 + \eta_j^2} < 1.
\]

Very similarly, one sees that

\[
\int_{\mathcal{G}_e} \frac{\Delta^2 |z - e|^2 + \Delta^4 |z - e|}{|z - e - \Delta^2 \lambda_{e,j}|^4} \, dx < 1
\]

and it follows that

\[
\int_{\mathcal{G}_e} e^{it\omega} \tilde{T}_j \, dz < 1.
\]

Next, using Cauchy’s integral formula as above \((\text{3.19})-(\text{3.21})\), we obtain that

\[
\int_{\mathcal{G}_e} e^{itz} \frac{Q_j(e)}{(z - e - \Delta^2 a_j(e))^2} \, dz = 2\pi i e^{it(e + \Delta^2 a_j(e))} Q_j(e) + O(e^{wt}/t).
\]

Combining \((\text{3.33})\) with \((\text{3.27})\) and \((\text{3.32})\), we see that for all \(j \geq 1\),

\[
\frac{1}{2\pi i} \int_{\mathcal{G}_e} e^{it\omega} \langle \phi, T_j \psi \rangle \, dz = e^{it(e + \Delta^2 a_j(e))} \langle \phi, Q_j(e) \psi \rangle + O(1/t + e^{wt}/t^2).
\]

At this point, it is instructive to explain the coefficient \((1 - \Delta^2 a_0'(E_e))^{-1}\) in front of the non-decaying term in \((\text{3.22})\). Let \(\Pi_{E_e}\) be the projection onto the embedded eigenvalue \(E_e\) of \(L\). We have (in the strong sense) \(\Pi_{E_e} = \lim_{\epsilon \to 0+} (i\epsilon)(L - E_e + i\epsilon)^{-1}\), so by \((\text{1.26})\),

\[
\Pi_{E_e} = \lim_{\epsilon \to 0+} (i\epsilon) \left\{ \tilde{\mathcal{F}}(L - E_e + i\epsilon; P_e)^{-1} + \mathcal{B}(E_e - i\epsilon) + R_{E_e - i\epsilon}^{P_e} \right\}.
\]

The \(P_e\)-block of the decomposition is, by \((\text{3.14})\),

\[
P_e \Pi_{E_e} P_e = \lim_{\epsilon \to 0+} (i\epsilon) \tilde{\mathcal{F}}(L - E_e + i\epsilon; P_e)^{-1} = \lim_{\epsilon \to 0+} \sum_{j=0}^{m_e-1} e^{-E_e + i\epsilon + \Delta^2 a_j(E_e - i\epsilon)} Q_j(E_e - i\epsilon).
\]

For \(j \geq 1\), we have \(\text{Im} a_j(E_e) > 0\) and the corresponding term in the sum vanishes in the limit \(\epsilon \to 0\). Hence

\[
P_e \Pi_{E_e} P_e = \lim_{\epsilon \to 0+} (i\epsilon) \frac{Q_0(E_e - i\epsilon)}{e - E_e + i\epsilon + \Delta^2 a_0(E_e - i\epsilon)} = \frac{Q_0(E_e)}{1 - \Delta^2 a_0'(E_e)}.
\]

We have used the relation \(e - E_e + \Delta^2 a_0(E_e) = 0\) (see after \((\text{3.15})\)). Therefore, the non-decaying, oscillating term on the right side in \((\text{3.22})\) is

\[
e^{itE_e} \frac{Q_0(E_e)}{1 - \Delta^2 a_0'(E_e)} \langle \phi, Q_0(E_e) \psi \rangle = e^{itE_e} \langle \phi, P_e \Pi_{E_e} P_e \psi \rangle.
\]
Finally, we combine (3.22), (3.34) and (3.38) to arrive at

\[
\frac{1}{\sqrt{2\pi i}} \int_{\mathcal{G}_e} e^{itz} \langle \phi, \frac{d}{dz} \tilde{\mathcal{B}}(z)^{-1} \psi \rangle dz = e^{itE_e} \langle \phi, P_e \Pi E_e P_\psi \rangle + \sum_{j=1}^{m_e-1} e^{it(e + \Delta^2 a_j(e))} \langle \phi, Q_j(e) \psi \rangle
\]

(3.39) 

\[+ O(1/t + e^{wt}/t^2).\]

On the right side appears the $P_e$-block $P_e \Pi E_e P_\psi$ of the projection $\Pi E_e$. The contributions of the terms in (3.12) with $\mathcal{B}(z)$ and $R^P_e$ will add the remaining blocks to finally give the full expression $\langle \phi, \Pi E_e \psi \rangle$.

3.1.2. The contribution to (3.12) from $\frac{d}{dz} \mathcal{B}(z)$. From (3.13) and (3.14), we have

\[
\frac{d}{dz} \langle \phi, \mathcal{B}(z) \psi \rangle = \Delta \sum_{j=0}^{m_e-1} \frac{1 - \Delta^2 a_j}{(z - e - \Delta^2 a_j)^2} q_j + \frac{1}{e - z + \Delta^2 a_j} q'_j,
\]

where

\[
q_j(z) = - \langle \phi, [Q_j P_e IR^P_e + R^P_e IP_e Q_j - \Delta R^P_e IP_e Q_j P_e IR^P_e] \psi \rangle.
\]

The summand in (3.40) is of the same form as $T_j$ in (3.15), with $Q_j$ replaced by $q_j$. We may thus repeat the analysis leading to (3.22) and (3.34), giving

\[
\frac{1}{\sqrt{2\pi i}} \int_{\mathcal{G}_e} e^{itz} \frac{d}{dz} \langle \phi, \mathcal{B}(z) \psi \rangle dz = e^{itE_e} \Delta \frac{q_0(E_e)}{1 - \Delta^2 a_0'(E_e)} + \Delta \sum_{j=1}^{m_e-1} e^{it(e + \Delta^2 a_j(e))} q_j(e)
\]

\[+ C(\phi, \psi) \cdot O \left( |\Delta|/t + |\Delta| e^{wt}/t^2 \right).
\]

Recalling (3.35), (3.37) and using that $R^P_{E_e - i\epsilon}$ stays bounded as $\epsilon \to 0^+$, we get

\[
\langle \phi, \Pi E_e \psi \rangle = \lim_{\epsilon \to 0^+} (i\epsilon) \langle \phi, \{ \tilde{\mathcal{B}}(L - E_e + i\epsilon; P_e)^{-1} + \mathcal{B}(E_e - i\epsilon) \} \psi \rangle
\]

(3.43) 

\[= \langle \phi, P_e \Pi E_e P_\psi \rangle + \frac{\Delta q_0(E_e)}{1 - \Delta^2 a_0'(E_e)}.
\]

3.1.3. The contribution to (3.12) from $\frac{d}{dz} R^P_e$. By assumption (A2), (1.54), we have $\langle \phi, \frac{d}{dz} R^P_e \psi \rangle < 1$ and so we get

\[
\frac{1}{\sqrt{2\pi i}} \int_{\mathcal{G}_e} e^{itz} \langle \phi, \frac{d}{dz} R^P_e \psi \rangle dz < \frac{C(\phi, \psi)}{t}.
\]

(3.44)

Combining (3.12), (3.39), (3.42), (3.43) and (3.44) gives (3.39). This concludes the proof of Proposition 3.2. \qed
3.2. Estimates for $z$ in a vicinity of an unstable eigenvalue $e$. The analysis is the same, actually somewhat easier, than the one presented in Section 3.1. Indeed, for an unstable eigenvalue $e$, all the $\lambda_{e,j}$ have strictly positive imaginary part (see Assumption (A4), (1)). Therefore, we can proceed as in Section 3.1 and in (3.15), all the terms $T_j$ (even for $j = 0$) are now treated as above, after (3.22). We immediately obtain the following result.

**Proposition 3.3.** We have, for $\phi, \psi \in D$,

$$J_e(t) = \sum_{j=0}^{m_e-1} e^{it(e+\Delta^2a_{e,j}(e))} \langle \phi, (Q_j(e) + \Delta \tilde{Q}_j)\psi \rangle + R_e(t)$$

where (recall that $w > 0$ is the arbitrary parameter in (1.18))

$$|R_e(t)| \lesssim C \frac{1 + e^{wt}/t}{t},$$

for a constant $C$ independent of $\Delta, t, w$ and

$$a_{e,j}(e) = \lambda_{e,j} + O(|\Delta|), \quad Q_j(e) = P_{e,j} + O(|\Delta|).$$

Also $\tilde{Q}_j$ is defined in (3.3).

3.3. Estimates for $z$ away from the eigenvalues $e$. On the unbounded set $\mathcal{G}_\infty$ we use the relation (1.39). This will help to ensure that the integrand is decaying sufficiently quickly at infinity. Setting $\tilde{\phi} = (L - i)\phi$ and $\tilde{\psi} = (L + i)\psi$,

$$\int_{\mathcal{G}_\infty} e^{itz} \langle \phi, \frac{d}{dz} R_z \psi \rangle dz = \int_{\mathcal{G}_\infty} e^{itz} \left\{ \frac{-2\langle \tilde{\phi}, R_z \tilde{\psi} \rangle}{(z+i)^3} + \frac{\langle \tilde{\phi}, \frac{d}{dz} R_z \psi \rangle}{(z+i)^2} \right\} dz$$

$$+ \int_{\mathcal{G}_\infty} e^{itz} \left\{ \frac{\langle \tilde{\phi}, \tilde{\psi} \rangle}{(z+i)^2} + \frac{2\langle \phi, \tilde{\psi} \rangle}{(z+i)^3} \right\} dz. \tag{3.47}$$

The integral (3.47) is $\lesssim \|\phi\| \|L\psi\|$. The terms on the right side of (3.47) involving $R_z$ and $\frac{d}{dz} R_z$ are estimated using Assumption (A2)(2). Thus

$$\frac{1}{i} \frac{1}{2\pi i} \int_{\mathcal{G}_\infty} e^{itz} \langle \phi, \frac{d}{dz} R_z \psi \rangle dz \lesssim \frac{C(\tilde{\phi}, \tilde{\psi})}{t}. \tag{3.48}$$

We have proven the following result.

**Proposition 3.4.** We have

$$J_\infty(t) \lesssim \frac{C((L - i)\phi, (L + i)\psi)}{t}. \tag{3.50}$$

3.4. Proof of Theorem 1.1. We combine the estimates in Propositions 3.2, 3.3 and 3.4 to obtain the expansion (1.13) with the bound

$$|R(t)| \lesssim \frac{1 + e^{wt}/t}{t}$$

for the remainder. Since $w > 0$ is arbitrary, we have $|R(t)| \lesssim 1/t$. \qed
A.1. From the global to the local limiting absorption principles. In this appendix, we derive the limiting absorption principle with projection $P_e$, $e \in \text{spec}(L_S)$, from that with projection $P_R$ given in Theorem 2.1 (2.17). Let

$$R^P_z = (P_e^L P_e^\perp - z)^{-1} \upharpoonright_{\text{Ran}P_e^\perp}$$

and recall the definition of the energy gap $g_e$. (1.20).

**Theorem A.1.** Assume the conditions of Theorem 2.1 Then, for $\varphi, \psi \in D$,

$$\sup_{z \in \mathbb{C} - |z - e| < g/2} \left| \frac{d^k}{dz^k} \langle \phi, R^P_z \psi \rangle \right| = C(\phi, \psi) < \infty, \quad k = 0, \ldots, 3.$$  

Moreover, suppose that for $\varphi, \psi \in D$, $\sup_{z \in \mathbb{C} -} \left| \frac{d^k}{dz^k} \langle \phi, R^P_z \psi \rangle \right| \leq C(\phi, \psi)$, $k = 0, 1$. Then, for all $e$,

$$\sup_{z \in \mathbb{C} -} \left| \frac{d^k}{dz^k} \langle \phi, R^P_z \psi \rangle \right| \leq C(\phi, \psi), \quad k = 0, 1.$$  

(Note: the constants $C(\phi, \psi)$ may differ from the one in (2.17).)

**Proof.** We first show (A2)(1) by expressing $R^P_z$ in terms of $R^R_z$ and then using the bound (2.17). To do so, consider the operator

$$K = P_e^L L P_e^\perp + i P_e,$$

where $i$ is the imaginary unit. We have $(K - z)^{-1} = (i - z)^{-1} P_e \oplus R^P_z P_e^\perp$ and therefore

$$R^P_z = (K - z)^{-1} P_e^\perp = P_e^\perp (K - z)^{-1} P_e.$$

Next, denote

$$\bar{\mathfrak{F}}_z \equiv \mathfrak{F}(K - z; P_R).$$

Then by (B.2) (with $Q = P_R \equiv 1_S \otimes |\Omega_R\rangle \langle \Omega_S|$)

$$(K - z)^{-1} = \begin{pmatrix} 1 & 0 \\ -\Delta R^R_z P_R^\perp \bar{P}_e & 1 \end{pmatrix} \begin{pmatrix} \bar{\mathfrak{F}}_z^{-1} & 0 \\ 0 & \bar{R}_z^R \end{pmatrix} \begin{pmatrix} 1 & -\Delta \bar{P}_e I P_R^\perp R^R_z \bar{P}_e \\ 0 & 1 \end{pmatrix},$$

where we have set

$$\bar{P}_e = 1 [L_S \neq e] P_R = P_e^\perp P_R.$$

By the assumptions of Theorem 2.1 \forall $\psi \in D$ the maps $z \mapsto \bar{P}_e I P_R^\perp R^R_z \psi$ and $z \mapsto \langle \psi | R^R_z P_R^\perp I \bar{P}_e$ are three times differentiable with bounded derivatives for $z \in \mathbb{C} -$. Next, since $P_e^\perp P_R^\perp = P_e$ and $P_R^\perp P_e = 0$, we have $(P_R^\perp K P_R^\perp - z)^{-1} \upharpoonright_{\text{Ran}P_R^\perp} = R^R_z$ and so

$$\bar{\mathfrak{F}}_z = (i - z) P_e \oplus \bar{P}_e (L_S - z + \Delta I - \Delta^2 I R^R_z I) \bar{P}_e.$$  

Since $P_R I P_R < 1$ and $P_R I R^R_z I P_R < 1$, we have

$$(i - z)^{-1} P_e \oplus (L_S - z)^{-1} \bar{P}_e (1 + O(\Delta))$$
provided \( z \in \mathbb{C}_- \) and \(|\text{Re}z - e| \leq \frac{1}{2}g \). The remainder term in (A.8) is uniform in these \( z \) and thus, for \( \Delta \) small enough, \( \delta^{-1}_z < 1 \). We obtain
\[
\frac{d}{dz} \delta^{-1}_z = -\delta^{-1}_z \left[ \frac{d}{dz} \delta_z \right] \delta^{-1}_z < 1
\]
and, taking further \( z \)-derivatives,
\[
\frac{d^k}{dz^k} \delta^{-1}_z < 1, \quad k = 0, \ldots, 3.
\]
(A.9)

Combining (A.4), (A.6), (A.9) and the regularity (first three \( z \)-derivatives bounded for \( z \in \mathbb{C}_- \)) of the matrices to the left and right in (A.6) discussed above yields the result (A3)(1).

To prove (A4)(2), the limiting absorption principle away from the eigenvalues of \( L_0 \), we apply the Feshbach map with projection \( P_R = 1_S \otimes |\Omega_R\rangle \langle \Omega_R| \),
\[
(A.10) \quad \mathcal{F}(z) \equiv \mathcal{F}(L - z, P_R) = P_R(L_S + \Delta I - z - \Delta^2 IR_z^{P_R}I)P_R.
\]

According to the decomposition (1.26),
\[
(A.11) \quad \langle \phi, \frac{d}{dz} R_z \psi \rangle = \langle \phi, \frac{d}{dz} \mathcal{F}(z)^{-1} \psi \rangle + \langle \phi, \frac{d}{dz} \mathcal{B}(z) \psi \rangle + \langle \phi, \frac{d}{dz} R_z^{P_R} \psi \rangle,
\]
where
\[
(A.12) \quad \mathcal{B}(z) = -\Delta \mathcal{F}(z)^{-1} P_R IR_z^{P_R} - \Delta R_z^{P_R} I P_R \mathcal{F}(z)^{-1} + \Delta^2 R_z^{P_R} I P_R \mathcal{F}(z)^{-1} P_R IR_z^{P_R}.
\]
For any \( z \in S_\infty \), we have \(||(L_S - z)^{-1}|| \leq 1/\alpha \) and therefore
\[
(A.13) \quad \mathcal{F}(z)^{-1} = (L_S - z)^{-1} \left[ 1 + \Delta P_R(I - \Delta IR_z^{P_R}I)P_R(L_S - z)^{-1} \right]^{-1} < 1.
\]

We then obtain at once from (A.13), (A.12) and (2.17) that
\[
(A.14) \quad \frac{d}{dz} \mathcal{F}(z)^{-1} < 1, \quad \langle \phi, \frac{d}{dz} \mathcal{B}(z) \psi \rangle \leq |\Delta| C(\phi, \psi), \quad \langle \phi, \frac{d}{dz} R_z^{P_R} \psi \rangle \leq C(\phi, \psi).
\]
The bounds (A.14) together with (A.11) imply (1.6).

Finally, we prove (A.2). We use again relations (A.4) and (A.6) to express \( R_z^{P_R} \) in terms of \( R_z^{P_e} \). Taking the \( \Delta \)-derivative in (A.6) results in taking \( \Delta \)-derivatives of \( R_z^{P_e} \) and \( \delta^{-1}_z \). The first one is controlled by the assumption in Theorem (A.1) the second one is controlled by (A.7) (as for the \( z \)-derivatives above).

### A.2. Proof of Theorem 2.3

For \( \eta > 0 \), we introduce the regularized Liouville operator (see (23))
\[
(A.15) \quad \mathcal{L}(\eta) = \mathcal{L}_0 + i\eta N + \Delta I, \quad \text{with} \quad I(\eta) = (2\pi)^{-1/2} \int_R \tilde{f}(s) \tau_{\eta s}(I) ds,
\]
and where \( \tau_t(X) = e^{-itA}Xe^{itA} \) with \( A = d\Gamma(i\partial_u) \). Here, \( f \) is a Schwartz function satisfying \( f^{(k)}(0) = 1, \ k = 0, 1, \ldots \)

The strategy of the proof is to derive estimates (2.31), (2.32) for \( \mathcal{L} \) replaced by the regularized \( \mathcal{L}(\eta) \), namely,
\[
(A.16) \quad \sup_{z \in \mathbb{C}_-} |\frac{d^{\mu-1}}{dz^{\mu-1}} \langle \phi, R_z^{P_R}(\eta) \psi \rangle| < \|\phi\|_{\mu,2\mu} \|\psi\|_{\mu,2\mu}
\]
\[
(A.17) \quad \sup_{z \in \mathbb{C}_-} |\frac{d}{dz} \langle \phi, R_z^{P_R}(\eta) \psi \rangle| < \|\phi\|_{3,1} \|\psi\|_{3,1}.
\]
Here, $\prec$ means $\text{(1.12)}$ with a constant not depending on $\eta > 0$. Then, since $\frac{d^{\mu-1}}{d\eta^{\mu-1}}\langle \phi, R^\mu \psi \rangle \rightarrow \frac{d^{\mu-1}}{d\eta^{\mu-1}}\langle \phi, R_\Delta^\mu \psi \rangle$ and since $\frac{d}{d\eta}\langle \phi, R^\mu \psi \rangle \rightarrow \frac{d}{d\eta}\langle \phi, R_\Delta^\mu \psi \rangle$ as $\eta \rightarrow 0^+$, (2.31), (2.32) follow from (A.16), (A.17).

Throughout this proof, we will not indicate the dependence of $\mathcal{L}$ and $I$ on $\eta$ and $\Delta$. We will also simply write $P$ instead of $P_{\text{R}}$. In particular, $R^P_{\Delta} = (\mathcal{L}_0(\eta) - z)^{-1}$, where $X = \mathcal{P}_{\text{R}}^\perp X\mathcal{P}_{\text{R}}^\perp |_{\text{Ran} P_{\text{R}}}^\perp$.

Let $X_\eta$ be an $\eta$-dependent bounded operator in $\mathcal{B}(\mathcal{P}\mathcal{H})$ which is sufficiently regular in $\eta > 0$. We define $\text{ad}_A(X_\eta) = [A, X_\eta]$, where $\partial X_\eta = \frac{d}{d\eta}X_\eta - \text{ad}_A(X_\eta)$. Note that $\partial \mathcal{L}_0 = 0$ (recall that we write $\mathcal{L}_0 \equiv \mathcal{L}_0(\eta)$). Since $\partial$ is a derivation we have, according to Leibniz' rule,

(A.18) \[ \partial R^P_{\Delta} = -\Delta R^P_{\Delta} (\partial I) R^P_{\Delta}, \]

and for $\mu \geq 1$,

(A.19) \[ \partial[R^P_{\Delta}]^\mu = -\Delta \sum_{j=1}^\mu [R^P_{\Delta}]^j (\partial I) [R^P_{\Delta}]^{\mu-j+1}. \]

It follows that

(A.20) \[ \frac{d}{d\eta}\langle \phi, [R^P_{\Delta}]^\mu \psi \rangle = \langle \phi, \text{ad}_A[R^P_{\Delta}]^\mu \psi \rangle + \langle \phi, \partial[R^P_{\Delta}]^\mu \psi \rangle \]

(A.21) \[ \langle \phi, [R^P_{\Delta}]^\mu \psi \rangle = \langle A\phi, [R^P_{\Delta}]^\mu \psi \rangle - \langle [R^P_{\Delta}]^\mu \phi, A\psi \rangle + \langle \phi, \partial[R^P_{\Delta}]^\mu \psi \rangle. \]

We are going to establish bounds on the right hand side.

**Proposition A.2** (23). (1) Suppose the form factor $f_\beta$ (see (2.26)) satisfies $\partial_j f_\beta \in L^2(\mathbb{R} \times S^2, du \times d\Sigma)$, for $j = 0, \ldots, \ell + 1$. Then, for $\ell \geq 1$,

(A.22) \[ \| \tilde{N}^{-1/2}(\partial I) \tilde{N}^{-\ell/2} \| \prec \eta^\ell. \]

(2) We have

(A.23) \[ \| \tilde{N}^{1/2} R^\ell \tilde{N}^{1/2} \| \prec \eta^{-1}, \]

(A.24) \[ \| \tilde{N}^{1/2} R^\ell \psi \| \prec \eta^{-1/2} \| \tilde{N}^{-1/2}(1 + A^2)^{1/2} \|, \]

(A.25) \[ \| \tilde{N}^{\ell/2} R^\ell \psi \| \prec \eta^{-1} \| \tilde{N}^{(\ell-2)/2} \tilde{N}^{\ell/2} \psi \| + \eta^{-1} \| \tilde{N}^{(\ell-2)/2} \psi \|, \quad \ell \geq 2. \]

In the arguments below in this proof, the biggest value of $\ell$ in (A.22) we will use is $\ell = 2\mu$. Hence the regularity condition on $f_\beta$ in the Theorem 2.3. Combining (A.23) with (A.24) we get for $j = 1, 2, \ldots$

(A.26) \[ \| \tilde{N}^{1/2} [R^\ell \psi] \| \prec \eta^{-j+1/2} \| \tilde{N}^{-1/2}(1 + A^2)^{1/2} \|. \]

Moreover, from (A.25) we obtain for $j, \ell = 1, 2, \ldots$

(A.27) \[ \| \tilde{N}^{\ell/2} [R^\ell \psi] \| \prec \eta^{-[\ell/2]} \sum_{k=1}^\ell \| \tilde{N}^{1/2} [R^k \psi] \| \| \tilde{N}^{(\ell-2)/2} \psi \| + \sum_{k=1}^{[\ell/2]} \eta^{-k} \| \tilde{N}^{(\ell-2k)/2} \psi \|. \]

Since $\tilde{N} \geq 1$ and because of (A.26) we obtain for $j, \ell = 0, 1, \ldots$

(A.28) \[ \| \tilde{N}^{\ell/2} [R^\ell \psi] \| \prec \eta^{-[\ell/2]-j+1/2} \| \tilde{N}^{-1/2}(1 + A^2)^{1/2} \| + \eta^{-[\ell/2]} \| \tilde{N}^{\ell/2} \psi \|. \]
From (A.19) and (A.22) follows that

\[ |\langle \phi, \partial[R_z^P]^{\mu} \psi \rangle| \lesssim \eta^\ell \sum_{j=1}^{\mu} \|N^{-1/2}[R_z^P]^{j\phi}\| \|N^{\ell/2}[R_z^P]^{\mu-j+1}\psi\|. \]

Since (A.26) holds with \([R_z^P]\) replaced by \([R_z^P]^*\), we may apply (A.26) and (A.28) to (A.29) and obtain

\[ |\langle \phi, \partial[R_z^P]^{\mu} \psi \rangle| \lesssim \eta^\ell \sum_{j=1}^{\mu} \eta^{-j+1/2}\|N^{-1/2}(1 + A^2)^{1/2}\phi\|
\times \left( \eta^{-[\ell/2]} - \mu - j - 1/2\|N^{-1/2}(1 + A^2)^{1/2}\psi\| + \eta^{-[\ell/2]}\|N^{\ell/2}\psi\| \right)
\lesssim \eta^{\ell/2} - \mu \|\phi\|_{1,\ell} \|\psi\|_{1,\ell}.
\]

By (A.21) we have

\[ \frac{d}{d\eta}\langle \phi, [R_z^P]^{\mu} \psi \rangle = \langle A\phi, [R_z^P]^{\mu} \psi \rangle - \langle [R_z^P]^{*\mu} \phi, A\psi \rangle + \langle \phi, \partial[R_z^P]^{\mu} \psi \rangle \]
and hence

\[ \frac{d}{d\eta}\langle \phi, [R_z^P]^{\mu} \psi \rangle \lesssim \|\tilde{N}^{-1/2}A\phi\| \|\tilde{N}^{1/2}[R_z^P]^{\mu} \psi\| + \|\tilde{N}^{-1/2}[R_z^P]^{*\mu} \phi\| \|\tilde{N}^{-1/2}A\psi\|
+ \|\phi\|_{1,2\mu} \|\psi\|_{1,2\mu}.
\]

By (A.26) we easily get

\[ \frac{d}{d\eta}\langle \phi, [R_z^P]^{\mu} \psi \rangle \lesssim \eta^{-\mu+1/2}\|\phi\|_{1,2\mu} \|\psi\|_{1,2\mu}.
\]

Since \(\langle \phi, [R_z^P]^{\mu} \psi \rangle = \langle \phi, [R_z^P(\eta = 1)]^{\mu} \psi \rangle - \int_{\eta}^{1} \frac{d}{d\eta'}\langle \phi, [R_z^P(\eta')]^{\mu} \psi \rangle d\eta'\), we conclude from (A.33) and from (A.26) for \(\eta = 1\) that

\[ \langle \phi, [R_z^P]^{\mu} \psi \rangle \lesssim (1 + \eta^{-\mu+3/2})\|\phi\|_{1,2\mu} \|\psi\|_{1,2\mu}.
\]

Let us now consider again (A.31), but instead of using (A.26) for an upper bound apply (A.34) to \(\langle A\phi, [R_z^P]^{\mu} \psi \rangle\) and \(\langle \phi, [R_z^P]^{*\mu} \psi \rangle\). In this way we get for (A.31) the upper bound

\[ \frac{d}{d\eta}\langle \phi, [R_z^P]^{\mu} \psi \rangle \lesssim (1 + \eta^{-\mu+3/2})\|\phi\|_{2,2\mu} \|\psi\|_{2,2\mu}.
\]

Now we integrate (as before (A.34)) and obtain

\[ \langle [R_z^P]^{\mu} \psi \rangle \lesssim (1 + \eta^{-\mu+5/2})\|\phi\|_{2,2\mu} \|\psi\|_{2,2\mu}.
\]

The right side of (A.36) has a power of \(\eta\) reduced by one, as compared to the right side of (A.34), but \(\phi\) and \(\psi\) contribute in a stronger norm. We continue this procedure to conclude the proof of (A.16) as well as the bound

\[ \sup_{z \in \mathbb{C}} \frac{d}{d\eta} \frac{d^{-\mu}}{dz^{-\mu}} \langle \phi, R_z^{P\mu} \psi \rangle \lesssim \|\phi\|_{\mu+1,2\mu} \|\psi\|_{\mu+1,2\mu}.
\]

We now prove the bound (A.17). Note that

\[ \frac{d}{d\lambda}\langle \phi, R_z^{P\lambda} \psi \rangle = -\langle \phi, [R_z^P IR_z^P] \psi \rangle.
\]
We have (see \((\text{A.18})\))
\[
\partial[R^P_z I R^P_z] = -\Delta R^P_z (\partial I) R^P_z I R^P_z + R^P_z (\partial I) R^P_z - \Delta R^P_z I R^P_z (\partial I) R^P_z.
\]
Next, we use \((\text{A.22}), (\text{A.23})\) and \(|I| \leq 1\) to get
\[
\begin{align*}
|\langle \phi, \partial[R^P_z I R^P_z] \psi \rangle | &< \eta^{-1} \| \tilde{N}^{1/2} \{ R^P_z \} \phi \| \| R^P_z \psi \| + \eta^{-1} \| \tilde{N}^{1/2} \{ R^P_z \} \phi \| \| \tilde{N}^{1/2} R^P_z \psi \|
\end{align*}
\]
By \((\text{A.28})\) we have
\[
|\langle \phi, \partial[R^P_z I R^P_z] \psi \rangle | < \eta^{-1} \| \phi \|_2 \| \psi \|_2.
\]
Recall that
\[
\frac{d}{d\eta} \langle \phi, [R^P_z I R^P_z] \psi \rangle = \langle A\phi, [R^P_z I R^P_z] \psi \rangle - \langle [R^P_z I R^P_z] \phi, A\psi \rangle + \langle \phi, \partial[R^P_z I R^P_z] \psi \rangle.
\]
Due to \((\text{A.24})\), the first and the second expression on the right side are bounded above by a constant times \(\eta^{-1} \| \phi \|_2 \| \psi \|_2\). Thus we get from \((\text{A.42}), (\text{A.43})\)
\[
|\langle \phi, [R^P_z I R^P_z] \psi \rangle | < \eta^{-1} \| \phi \|_2 \| \psi \|_2.
\]
We integrate from \(\eta\) to 1 to obtain the estimate
\[
|\langle \phi, [R^P_z I R^P_z] \psi \rangle | < | \ln(\eta) \| \phi \|_2 \| \psi \|_2.
\]
Next, we use \((\text{A.45})\) in \((\text{A.43})\) to get the better upper bound
\[
|\langle \phi, [R^P_z I R^P_z] \psi \rangle | < | \ln(\eta) \| \phi \|_3 \| \psi \|_3.
\]
Integration from \(\eta\) to 1 yields \(|\langle \phi, [R^P_z I R^P_z] \psi \rangle | < \| \phi \|_3 \| \psi \|_3\), which, combined with \((\text{A.38})\), implies \((\text{A.17})\). This completes the proof of Theorem 2.3. \(\square\)

**APPENDIX B.**

Let \(Q\) be an orthogonal projection and let \(Q^\perp = 1 - Q\). Let \(H\) be a densely defined, closed operator satisfying \(\text{Ran}Q \subset \text{dom}(H)\). Let \(\hat{H}Q\) be the operator on \(\text{Ran}Q\), given by \(Q^\perp HQ^\perp\).

For \(z \not\in \sigma(HQ)\) we set \(R^Q_z = (\hat{H}Q - z)^{-1}\) and we assume that \(\| R^Q_z HQ \| \ll \infty\) and \(\| QHR^Q_z \| \ll \infty\). Then we define
\[
\mathfrak{F}_z \equiv \mathfrak{F}(H - z; Q) = Q(H - z - HQ^\perp R^Q_z Q^\perp H)Q.
\]

**Theorem B.1** (Feshbach-theorem, [5]). Let \(z \not\in \sigma(HQ)\).

1. We have
   \[
   z \in \sigma(H) \iff 0 \in \sigma(\mathfrak{F}_z)
   \]
   \[
   z \in \sigma_p(H) \iff \{0\} \neq \ker \mathfrak{F}_z
   \]
   If \(z \not\in \sigma(H)\) we have for \(R_z = (H - z)^{-1}\) that
   \[
   QR_z Q = \mathfrak{F}_z^{-1}, \quad Q^\perp R_z Q = -R^Q_z Q^\perp HQ \mathfrak{F}_z^{-1}, \quad QR_z Q^\perp = -\mathfrak{F}_z^{-1} Q H Q^\perp R^Q_z,
   \]
   \[
   Q^\perp R_z Q^\perp = R^Q_z + R^Q_z Q^\perp HQ \mathfrak{F}_z^{-1} Q H Q^\perp R^Q_z.
   \]
(2) If $Q$ has finite rank, we have the additional characterization
\[ z \in \sigma(H) \iff z \in \sigma_p(H) \iff \det(\mathcal{F}_z) = 0. \]

(3) Let $\mathcal{H}_E$ be the eigenspace of $H$ for $E \in \sigma_p(H)$. The restricted projection $Q|_{\mathcal{H}_E}$ is a bijection from $\mathcal{H}_E$ to $\ker \mathcal{F}_E$. Its inverse is
\[ \phi \mapsto \phi + R^Q_z Q^\perp HQ \phi. \]

The previous theorem is proven in [5]. Point (1) of the theorem gives the block representation
\[
R_z = \begin{pmatrix}
\tilde{\mathcal{F}}_z^{-1} & -\tilde{\mathcal{F}}_z^{-1} Q HQ^{-1} R^Q_z \\
-R^Q_z Q^\perp HQ \tilde{\mathcal{F}}_z^{-1} & R^Q_z + R^Q_z Q^\perp HQ \tilde{\mathcal{F}}_z^{-1} Q H Q^\perp R^Q_z
\end{pmatrix}
= \begin{pmatrix}
1 & 0 \\
-R^Q_z Q^\perp HQ & 1
\end{pmatrix}
\begin{pmatrix}
\tilde{\mathcal{F}}_z^{-1} & 0 \\
0 & Q^\perp(H - z) Q^\perp
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}.
\]

Note that the three matrices on the last line are both invertible. Thus (recall (B.1))
\[ H - z = \begin{pmatrix}
1 & Q HQ^\perp R^Q_z \\
0 & 1
\end{pmatrix}
\begin{pmatrix}
\tilde{\mathcal{F}}(H - z; Q) & 0 \\
0 & Q^\perp(H - z) Q^\perp
\end{pmatrix}
\begin{pmatrix}
1 & 0 \\
0 & R^Q_z Q^\perp HQ & 1
\end{pmatrix}. \]

**Remark.** If $Q'$ is another projection, satisfying $Q'Q = Q' = QQ'$, then
\[
\mathcal{F}(\mathcal{F}(H - z; Q); Q') = \mathcal{F}(H - z; Q').
\]

Indeed, from point (1) in the theorem, we know that
\[
[\mathcal{F}(\mathcal{F}(H - z; Q); Q')]^{-1} = Q'[\mathcal{F}(H - z; Q)]^{-1} Q' = Q'Q'R_z Q' = Q'R_z Q' = [\mathcal{F}(H - z; Q')]^{-1},
\]
which implies (B.3).

**Proposition B.2** (Weak Feshbach Theorem). Assume that $H$ is self-adjoint, $E \in \mathbb{R} \setminus \sigma_p(\mathbb{H}^Q)$, and that $\lim_{\epsilon \to 0^+} \mathcal{F}(H - E + i\epsilon; Q) \equiv \mathcal{F}(H - E; Q)$ exists (as a weak limit). If $E$ is an eigenvalue of $H$ with eigenvector $\psi$, then $0$ is an eigenvalue of $\mathcal{F}(H - E; Q)$ with eigenvector $Q\psi$.

**Proof.** Applying the projections $Q$ and $Q^\perp$ to the eigenvalue equation, we get for any $\epsilon > 0$
\[
Q(H - E + i\epsilon)Q^\perp \psi + QHQ^\perp \psi = i\epsilon Q^\perp \psi
\]
\[Q^\perp HQ^\perp \psi + Q^\perp(H - E + i\epsilon)Q^\perp \psi = i\epsilon Q^\perp \psi.
\]

Applying the resolvent $R^Q_{E-i\epsilon}$ to the second equality in (B.4) gives
\[
Q^\perp \psi = -R^Q_{E-i\epsilon} Q^\perp H Q^\perp \psi + i\epsilon R^Q_{E-i\epsilon} Q^\perp \psi.
\]

Using (B.3) in the first equation of (B.4), then letting $\epsilon \to 0^+$ and taking into account that
\[i\epsilon R^Q_{E-i\epsilon} Q^\perp \psi \to 1[H^Q = E] Q^\perp \psi = 0,
\]
gives $\mathcal{F}(H - E; Q) \psi = 0$. (Note that $Q^\perp \psi \neq 0$ for otherwise, one easily obtains from the second equality in (B.4) that $Q^\perp \psi = 0$ as well.) \qed
