Abstract
The purpose of this paper is to study the interaction of time and negation in natural language, from a syntax/semantics interface point of view. This requires the definition of linguistically grounded semantic and syntactic representations. This is what we present in this paper; we show how the two representations we propose fit together in a computationally satisfying construction procedure.

1 Introduction
We are concerned in this paper with the interaction between time and negation in formal semantics, more precisely in the Discourse Representation Theory framework (Kamp and Reyle, 1993). We are interested here in the compositional construction of semantic representations.

We want to show, through linguistic arguments, that the best semantic representation (at least for sentential negation) gives negation a wide scope over events or states, and that the syntactic results correspond with the semantic ones.

2 Semantic representation
DRT handles events as objects in the language. Thus, each simple sentence introduces into the representation (at least) one discourse referent, either an event or a state, corresponding to the eventuality denoted by the VP.

With this in mind, negation can either be seen as an operator always having a wide scope over events/states, or as a kind of aspectual operator. According to the first view, negation would semantically convey only negative information ("such an eventuality x didn't occur"). According to the second view, negative sentences convey some kind of positive information, at the semantic level: they denote a certain kind of eventuality.

We want to address this problem here, with a focus on sentential negation in French.

2.1 The problem
As we have already said, the two approaches to sentential negation differ with respect to the scope they assign to the negation operator. To help illustrate this, we shall use the following example, where we assume that (1b) is the (sentential) negation of (1a). A "standard" representation of (1a) is $K_{1a}$.

\begin{itemize}
  \item (1a) Jean s'arrêta. (Jean stopped.)
  \item (1b) Jean ne s'arrêta pas. (Jean didn't stop.)
\end{itemize}

What $K_{1a}$ says is that there is an $x$, which is Jean, an event $e$, and a location time $t$, such that $e$ is the event of Jean stopping, $e$ is included in the location time $t$, which is itself located in the past, or the now. (1b) could then be represented either by $K_{1b}$ or by $K'_{1b}$.

$K_{1b}$ states something like "there is no event of Jean's stopping at the time $t". \ K'_{1b}$ introduces a "special" event, $e'$, which is defined in term of the negation of an another event.\footnote{The ontological and semantic properties of such special events remain to be defined, and the various proponents of this view propose different definitions - a sort of "maximal event" (Kripke, 1989), or a state consisting of the negation of an event (de Swart and Molendijk, 1994), for instance.}

2.2 Discussion
The position we are going to defend here is the one according to which negation should not be seen as...
an aspeural operator, but rather as having wide scope over the eventuality, as exemplified by the DRS $K_{1b}$. This position is the one defended in (Kamp and Reyle, 1993).

We first review the arguments in favour of our view, and then summarize the discussion presented in (Amsili and Le Draoulec, 1996) against the counter-arguments to this view presented in (de Swart and Molendijk, 1994). We summarize our semantic proposal in the section 2.3.

Simplicity. One of the reasons why we may prefer the representation $K_{1b}$ to $K_{1a}$ is that it is simpler, from the technical point of view. Thus, if such a representation is sufficient to account for all the data we want to account for, then there is no need for a more complex representation like the one exemplified in $K_{1a}$. Another point worth noting is that the second proposal is also more complex from the ontological point of view. Adding new types of discourse referents like $\bar{e}$ in the language of DRS requires that we define their ontological properties. And since these new kinds are defined in terms of others kinds of discourse referents, this may well be a non-trivial task.

Negation in discourse. The ideas developed in this paragraph are based on a study of negation in discourse currently in progress. The aim of this study is to see how negation interferes with so-called discourse relations (continuation, elaboration, explanation...). To do this, we are using a large corpus taken from French contemporary literature. We shall not describe this study in detail here; nevertheless, one of its findings is relevant to our discussion.

We have looked at examples involving French passé simple (PS, simple past). This tense typically introduces an event rather than a state. We have a set of 1399 examples of sentential negation, in which one find only 46 occurrences of PS. Among these examples, a majority are of the form exemplified in (3).

(3) a. Je ne lui répondis pas.
   *I didn't answer him.*

b. Elle ne sursauta pas.
   *She didn't startle.*

Thus, in a majority of cases, PS+negation seems to be used to assert the absence of an event, and it is very difficult in those cases to find a “real event” which could be seen as denoted by the sentence.

3 cases in the corpus seem however to suggest that negated event sentences may denote events:

(4) a. Elle ne le voulut pas.
   *She didn't want it.*

b. L’autre ne prit pas de détour.
   *The other didn't mince words.*

c. Elle ne se laissa pas faire.
   *She didn't let things flow.*

Thus, one can easily imagine that (4a) “refers to” a gesture, or some kind of behaviour that could be interpreted as a refusal. Here, of course, this refusal could probably be associated with $\bar{e}$.

But these examples are rare; moreover, the two last sentences of (4) involve more or less idiomatic expressions, so that it seems quite reasonable to see negation here as part of a conventionalised expression (“ne pas se laisser faire” denoting an event, just like the verb to refuse does).

Events can be defined as a change of state. With this definition in mind, we think that, at least in the case of PS, negation over events is used mostly to convey something like “nothing changed”, or “the expected event didn’t occur”, and there is in this case no event denoted by the sentence. There remain some cases (very few) where such sentences seem to denote some real change of the background, but then we claim that negation is lexically incorporated, and no longer sentential.

The classical example. We come now to the “classical” example of (Kamp and Reyle, 1993). It involves the following discourses:

(5) a. Mary looked at Bill. He smiled.
   b. Mary looked at Bill. He was smiling.
   c. Mary looked at Bill. He didn’t smile.
   d. Mary looked at Bill. He wasn’t smiling.

The pair (5a-5b) exemplify the contrast between simple past and progressive past in narrative discourse. In the second sentence of (5a), the simple past introduces a new event, which is localized after the event introduced in the previous sentence. In contrast, the second sentence of (5b) introduces a state, which overlaps with the event of the previous sentence. This analysis gives the correct prediction for the contrast: in (5a), Bill’s smiling is interpreted as a reaction to Mary’s looking at Bill, thus following it, whereas in (5b), Bill was already smiling when Mary looked at him.

The contrast in (5c-5d) is clearly parallel to that in (5a-5b). Since the second sentence of (5d) can reasonably be thought of as introducing a state, also introducing a state for the second (negative) sentence of (5c) would lead us to lose the contrast, since this would suggest for both sentences that Bill was not smiling when Mary looked at him.

Counter-arguments. We summarize here the discussion given in (Amsili and Le Draoulec, 1996) against some of the arguments given in favour of the idea that negative sentences denote an eventuality. There are two main arguments. One is based on the fact that negated event sentences accept durative complements (whereas their positive counterpart do not), this fact being taken as an argument in favour of the aspeural role of negation. Our answers are: first, some French data suggest that durative complements with negation should
not always be seen as demonstrating the durability of the predicate; second, Kamp and Reyle's (1993) representation provides a satisfying way to account for such data. The second argument is based on examples in which an anaphoric reference seems to be made to the denotation of negative sentences, therefore suggesting that they have one. But these data are rather constrained, in such a way that it seems that the discourse at stake is an abstract one, namely a fact, and not an event/state.

2.3 Proposal

We can now state the proposal, in the terms of (Kamp and Reyle, 1993, p. 548). Roughly, the interpretation of a negated sentence induces the following steps in the construction of a DRS:

- introduction of a location time t;
- introduction of a condition relating t with the speech time n;
- introduction of a condition saying that there is no event or state of a certain type which stands in the relation 'C' or 'O' to t.

As an example, the discourse (5c) will receive the representation (6), the most relevant points of which being, first, that a temporal constant (t) is systematically introduced into the representation, and second, that negation has wide scope over event/state discourse referents, t remaining outside negation.

3 Syntactic Aspects

We now briefly address the syntactic aspects of French sentential negation. We adopt the representations envisioned by classical Government and Binding Theory (hereafter GB, Chomsky (1981; 1986)). Several studies on the structure of French clauses, and in particular, negative sentences, have been carried out more recently in this framework by Pollock (1989; 1993), Hirschbühler and Labelle (1993; 1994a) and Pearce (1994) among others. In this section, we adopt some of their most relevant results.

We are mainly concerned with two of the four levels of representation of GB, namely D-Structure and S-Structure. The representations of these two levels are trees. D-structures represent basic lexical properties such as thematic relations. S-structures represent more superficial properties such as case, binding, etc. S-structures derive from D-structures via Move-α: they are the result of movements that take place in the latter.

In this section, we attempt to answer the following two questions: (1) what is the D-structure of French negative clauses? (2) which movements take place between D-Structure and S-Structure?

3.1 Split Inflexion Hypothesis

The French clause representations we use are rather classical. They satisfy X'-theory, which uses well-known syntactic concepts independent of any theoretical framework. To represent clauses and to build their DRSs, we use a tree structure consisting of a verb phrase VP dominated by the projection IP of a functional head I bearing the verbal tense and agreement features (I stands for inflexion). IP has the sentence subject NP as its specifier and the VP as the complement of its head. The sentence is therefore represented as an "inflexional phrase." This may be illustrated by the S-structure (7b) of sentence (7a); (7b) may also be represented as the labelled bracketing given in (7c).

\[
\text{(7) a. Julie regarde Marc (Julie looks at Marc.)}
\]

\[
\text{b. IP}
\]

\[
\text{VP}
\]

\[
\text{V'}
\]

\[
\text{regarde} - e
\]

\[
\text{NP}
\]

\[
\text{Julie}
\]

\[
\text{Marc}
\]

\[
\text{t}
\]

\[
\text{(7c) [IP [NP Julie] [V' [r [V, regarde] [r -e] [VP [V' [V, t] ]]]]]]]
\]

Pollock (1989), starting from this general structure, gives a new insight into the problem, by showing the benefits of splitting the complex inflexional category I into two distinct functional categories, namely tense (T) and verb agreement (Agr). The general structure of French clauses that Pollock (1989) proposes is (8a), so that for instance (7b) becomes (8b):

\[
\text{(8) a. IP [NP T [Agr] Agr [VP (AdvP) VP]]}
\]

\[
\text{b. IP [NP Julie] [T, [r, regarde] Agr [Agr] [Agr'] [Agr] t] [VP [V, t] [NP Marc]]]]
\]

3.2 Negation

(Pollock, 1989) also claims that negation, like tense and verb agreement, is represented as a functional category, Neg, located between T and Agr.

\[
\text{Note that the morphological decomposition of the verb, shown in (7b), will not be made explicit in the following representations.}
\]
In French, this category contains the negative item ne, seen as a weak affix lacking morphological stress. In S-Structure, ne must adjoin to the verb as a clitic. More generally, it must raise to T in finite clauses as well as infinitives.

This proposal has been accepted by many linguists. However, there is no similar consensus about the position in D-Structure and the possible movements of the second element of French negation, namely one of the adverbs pas, plus, point, guère, etc. Here we adopt the proposal of (Hirschbühlé and Labelle, 1993) which states that pas (or any of the other negative adverbs) is an adjunct to the maximal projection governed by Neg. Since Neg is located between T and Agr, this projection is AgrP. The general structure of a French negative clause is therefore:

\[ \left[ TP \ NP \ T \ [NegP \ Neg \ [AgrP \ Agr \ [VP \ (AdvP) \ VP]]] \right] \]

3.3 The Aspectual Dimension of Agr

The previous clause structure improves significantly the correspondence between syntactic representation and semantic interpretation. In particular, it becomes easier to differentiate the semantic contribution of each element that is relevant at the aspectuo-temporal level. These elements fall into two categories: those below negation (and therefore inside its scope) and those above negation.

Following (de Freitas, 1994; Borer, 1993; Laka, 1990), we consider Agr to be rather an aspectual category Asp in charge of the aspectual dimension of the semantic representations. This dimension is introduced by discourse referents. Recall that DRT discourse referents do not serve only to account for this aspectual dimension, but do play a fundamental discursive role. Nevertheless, the categorisation into states (s) and events (e) of the utterances to be represented, and the possible introduction of the discourse referents of one of these aspectual categories, may be associated with the Asp head. This association gives us the expected result: the discourse referent e or s is in the scope (in the sense of DRS construction) of the possible negation.

These elements are all illustrated in the complete syntactic representation of the sentence (9) given in figure 2. Notice the attachment of the sentential adverb aujourd'hui as adjunct to TP, the highest projection of the representation. Because of space limitation, we cannot develop this point here and refer the reader to (Amsili, 1994).

4 Bottom-up construction

We now integrate the semantics and the syntax of sentential negation. We show in this last section that both representations fit together in the framework of a bottom-up construction procedure, which allows a satisfactory computational treatment of negation. We use the method proposed in (Asher, 1993), presented in section 4.1, and then show how this method can be applied to the representations discussed earlier.

4.1 Principle

The construction procedure is bottom-up. DR-theoretic expressions are associated with leaves, and then combined to form the final DRS. The combinatorial method used here is \( \lambda \)-conversion, with two kinds of \( \lambda \)-expressions, namely predicative DRSs and partial DRSs. We associate verbs and nouns with predicative DRSs (for instance, the verb voir (see) yields \( \lambda x \lambda y \text{voir}(x,y) \)), the role of which is to introduce predicates into the representation. In constrast, discourse referents are only present in the form of \( \lambda \)-variables; they will be introduced by the partial DRSs. The translation of noun phrases (NP) or determiners is quite close to that of the Montagovian tradition. A determiner is associated with a partial DRS, which is, so to speak, what remains of a DRS when one takes away a predicative DRS. As a consequence, there will be variables over predicative DRSs (PDRS-variables) in partial DRSs. A partial DRS can also contain a declared discourse referent. This discourse referent is meant to serve as an argument of the predicative DRS which will be assigned to one PDRS-variable during the conversion. In (10) we give a graphical representation of a simple and general case of \( \lambda \)-conversion.

\[
\begin{align*}
\text{partial DRS} & \quad \text{pred. DRS} \\
\text{conversion} & \quad \lambda x \quad \Ax & \quad Ax \rightarrow u \\
\end{align*}
\]

We have no room here to elaborate on the details of the construction procedure; we refer the reader to (Asher, 1993), and give in figure 1 a complete example (with a simplified syntactic representation), for the sentence (11).

(11) Un gars voyait Marie

A boy was seeing Mary

4.2 Implementation

What remains to be done is to integrate this construction procedure with the proposals we have made in this paper. We cannot, in this short text, review all aspects of this integration, and will therefore mention only the most relevant points.

We have seen that the representation of time in DRT makes use of two discourse referents (at least). It is thus necessary to determine in both cases which node will be in charge of introducing the discourse referent. The pure temporal dimension, which is accounted for by the time referent t, will be introduced at the node T. The aspectual dimension, which is accounted for at the semantic level by the discourse referent e/s, is associ-
associated with the head Asp. We will therefore associate with this node a partial DRS to introduce the discourse referent. Finally, we have to take into account the possible role of temporal adverbials, which predicate over \( t \). We associate thus a predicative DRS with the node AdvP adjoined to TP. This leads to the complete treatment of time sketched here:

\[
\begin{array}{c}
\text{TP} \\
\text{AdvP} \\
\text{NP} \\
\text{M}\text{P}\text{AQ} \\
\end{array}
\]

What we have said so far should be sufficient to understand figure 2 (next page), which represents the construction procedure applied to the example (9).

5 Conclusion

This work shows the convergence of different approaches, from the syntax/semantic interface point of view. From a semantic point of view, it is possible to propose a semantic representation of temporal negation, and this representation matches in a way recent results in generative syntax, so that it is possible to offer a computationally realistic treatment of this interaction, without any trade-off from the linguistic point of view.
