Abstract

We provide a transformation formula of non-commutative Donaldson-
Thomas invariants under a composition of mutations. Consequently, we
get a description of a composition of cluster transformations in terms of
quiver Grassmannians.

Introduction

Donaldson-Thomas invariants (Tho00, MNOP06) are defined as the topological Euler characteristics (more precisely, the weighted Euler characteristics weighted by Behrend function Beh09) of the moduli spaces of sheaves on a Calabi-Yau 3-fold (more generally, the moduli spaces of objects in a 3-Calabi-Yau category Sze08, Joy08, KS, JS). Dominic Joyce introduced the motivic Hall algebra for an Abelian category in his study of generalized Donaldson-Thomas invariants (Joy07). One of the important results is that for a 3-Calabi-Yau category there exists a Poisson algebra homomorphism, so called the integration map, from the motivic Hall algebra to a power series ring (Joy07, JS, Brib). The integration map is given by taking the (weighted) Euler characteristic of an element in the motivic Hall algebra. Due to the integration map, we get the following powerful method in Donaldson-Thomas theory for 3-Calabi-Yau categories, which originates with Reineke’s computation of the Betti numbers of the spaces of stable quiver representations (Rei03):

Starting from a simple categorical statement, provide an identity in the motivic Hall algebra. Pushing it out by the integration map, we get a power series identity for the generating functions of Donaldson-Thomas invariants.

The aim of this paper is to provide

1. Theorem 5.7 (Theorem 0.1) : a transformation formula of the noncommutative Donaldson-Thomas invariants, and

2. Theorem 5.8 (Theorem 0.3) and the results in §8 : its application to the theory of cluster algebras

using this method.
Transformation formula of ncDT invariants

Let $Q$ be a quiver and $W$ be a potential. In this paper, we always assume that

- the quiver has the vertex set $I = \{1, \ldots, n\}$,
- the quiver has no loops and oriented 2-cycles, and
- the potential is finite, i.e. a finite linear combination of oriented cycles.

Let $J = J_{Q, W}$ be the (non-complete) Jacobi algebra. We have a 3-Calabi-Yau triangulated category (the derived category of Ginzburg’s dg algebra) with a t-structure whose core $A$ is the module category of the Jacobi algebra. It was proposed by B. Szendroi ([Sze08]) to study Donaldson-Thomas theory for the Abelian category $A \cong \text{mod}\, J$ (non-commutative Donaldson-Thomas theory).

For a vertex $i \in I$, let $P_i$ denote the projective indecomposable $J$-module corresponding to the vertex $i$. For a dimension vector $v \in (\mathbb{Z}_{\geq 0})^I$, let $\text{Hilb}_J(i; v)$ be the moduli scheme which parametrizes elements in $V \in \text{mod}\, J$ equipped with a surjection from $P_i$ such that $[V] = v$:

$$\text{Hilb}_J(i; v) := \{ V \twoheadrightarrow P_i \mid V \in A, [V] = v \}.$$  

The (Euler characteristic version of the) non-commutative Donaldson-Thomas invariant is defined by

$$\text{DT}_{J, +}(i; v) = e_+(\text{Hilb}_J(i; v)) := e(\text{Hilb}_J(i; v))$$

where $e(\bullet)$ denote the topological Euler characteristic. In the context of this paper, we will also deal with the invariant

$$\text{DT}_{J, -}(i; v) = e_-(\text{Hilb}_J(i; v))$$

where $e_-(\bullet)$ denote the weighted Euler characteristic weighted by the Behrend function (Definition 5.3).

For a vertex $k$, we assume that the mutation $\mu_k(Q, W)$ is well-defined. Due to the result by Keller and Yang, $(Q, W)$ and $\mu_k(Q, W)$ provide the same derived category with different t-structures ([KY], [Kelb]). Kontsevich and Soibelman ([KS]) observed that the cluster transformation appears in the transformation formula of non-commutative Donaldson-Thomas invariants under a mutation. In this paper, generalizing their observation, we provide a transformation formula of the non-commutative Donaldson-Thomas invariants under a composition of mutations.

They are called the semiclassical limits of quantum torus, quantum dual torus and quantum double torus respectively. They are taken as the group algebra of the lattices $M_Q$, $L_Q$ and $M_Q \oplus L_Q$ which are related to the Grothendieck group of the derived category (§2.2). Since we have derived equivalences between

---

1Since Spec of them are algebraic tori, we call them tori with a slight abuse.
We take a certain completion \( \hat{T}_{Q,\pm} \) of \( T_{Q,\pm} \) (\S 5.2.2). We define the generating function of the Donaldson-Thomas invariants by

\[
Z^j_{J,\pm}(i; v) := \sum_v \mathcal{D}T^j_{J,\pm}(i; v) \cdot y^v \]

where \( y^v := \prod(y_{i,\pm})^{e_{i,\pm}} \). Using the generating functions, we define algebra automorphisms \( \mathcal{D}T^j_{J,\pm} \) of \( \hat{T}_{Q,\pm} \) by

\[
\mathcal{D}T^j_{J,\pm}(x_{i,\pm}) := x_{i,\pm} \cdot Z^j_{J,\pm}, \quad \mathcal{D}T^j_{J,\pm}(y_{i,\pm}) := y_{i,\pm} \cdot \prod_j (Z^j_{J,\pm})^{Q(j,i)}
\]

where \( Q(j,i) := Q(i,j) - Q(j,i), \quad Q(i,j) = \sharp \{ \text{arrows from } i \text{ to } j \text{ in } Q \} \).

For a sequence of vertices \( k = (k_1, \ldots, k_l) \in I^l \), let \( \mu_k(Q, W) \) denote the new QP \( \mu_{k_1}(\cdots \mu_{k_l}(Q, W) \cdots) \) and \( J_k \) denote the Jacobi algebra associated to \( \mu_k(Q, W) \). Then we have two isomorphisms \( \mathcal{D}T^j_{J,\pm} \) and \( \mathcal{D}T^j_{J_k,\pm} \) of the torus \( \hat{T}_{Q,\pm} \).

In \( \S 5.1 \) we construct a \( J \)-module \( R_{k,i} \) and define the quiver Grassmannian which parametrizes quotient modules of \( R_{k,i} \):

\[
\text{Grass}(k; i, v) := \{ R_{k,i} \twoheadrightarrow V | V \in \mathcal{A}, [V] = v \}.
\]

The formula is described in terms of (weighted) Euler characteristics of the quiver Grassmannians.

**Theorem 0.1.** (= Theorem 5.7, transformation formula of ncDT invariants)

Assume that the \((Q, W)\) is successively f-mutable with respect to the sequence \( k \) (see \S 1.3.2 for the details of the assumption). Then we have the following “commutative diagram”:\(^3\)

\[
\begin{array}{ccc}
\hat{T}_{Q,\pm} & \xrightarrow{\text{Ad}_{\mathcal{T}_{[-1],\pm}}} & \hat{T}_{Q,\pm} \\
\mathcal{D}T_k \downarrow & & \mathcal{D}T_k \downarrow \\
\hat{T}_{Q_{k,\pm}} & \xrightarrow{\text{Ad}_{\mathcal{T}_{[-1],\pm}}} & \hat{T}_{Q_{k,\pm}}
\end{array}
\]

The morphism \( \text{Ad}_{\mathcal{T}_{[-1],\pm}} \) is given by

\[
\text{Ad}_{\mathcal{T}_{[-1],\pm}}(x_{k,i,\pm}) = x_{k,i,\pm} \cdot \left( \sum_v e_{v,\pm} \left( \text{Grass}(k; i, v) \right) \cdot y_{v,\pm}^v \right), \quad (0.1)
\]

\[
\text{Ad}_{\mathcal{T}_{[-1],\pm}}(y_{k,i,\pm}) = y_{k,i,\pm} \cdot \prod_j \left( \sum_v e_{v,\pm} \left( \text{Grass}(k; j, v) \right) \cdot y_{v,\pm}^v \right)^{Q(j,i)}, \quad (0.2)
\]

\(^2\)To be precise, they are isomorphisms of different completions. See Theorem 5.7 for the precise statement.

\(^3\)This diagram is not rigorous in that the compositions of the maps are not well-defined. See Theorem 6.1 for the precise statement.
where $x_{k,i,\pm}$ and $y_{k,i,\pm}$ are generators of $T_{Q_k,\pm}$. The morphism $\text{Ad}_{T_{k,\pm}}$ is given by

$$\text{Ad}_{T_{k,\pm}} := \Sigma \circ \text{Ad}_{T_{k,-1,\pm}} \circ \Sigma$$

(0.3)

where $\Sigma$ is the involution of the tori given by

$$\Sigma(x_{i,\pm}) = (x_{i,\pm})^{-1}, \quad \Sigma(y_{i,\pm}) = (y_{i,\pm})^{-1}.$$ 

If we take a sequence $k = (k)$ of length 1, then we have

$$R_{(k),i} = \begin{cases} 0 & i \neq k, \\ s_k & i = k. \end{cases}$$

Hence we have

$$\text{Ad}_{T_{(k),-1,\pm}}(x_{(k),i,\pm}) = \begin{cases} x_{(k),i,\pm} & i \neq k, \\ x_{(k),k,\pm}(1 + (y_{k,\pm})^{-1}) & i = k. \end{cases}$$

(0.4)

This recovers the results in [KS] pp143.

Composition of cluster transformations

Cluster algebras were introduced by Fomin and Zelevinsky ([FZ02]) in their study of dual canonical bases and total positivity in semi-simple groups. Although the initial aim has not been established, it has been discovered that the theory of cluster algebras has many links with a wide range of mathematics (see [Kela, §1.1] and the references there). Since a cluster transformation helps us to understand the whole structure in an inductive way, study of compositions of cluster transformations is important.

A seed is a pair $(Q | u)$, where

1. $Q$ is a quiver without loops and oriented 2-cycles, and
2. $u = (u_1, \ldots, u_n)$ is a free generating set of the field $\mathbb{C}(x_1, \ldots, x_n)$.

For a vertex $k \in I$, the mutation $\mu_k(Q | u)$ of $(Q | u)$ at $k$ is the seed $(\mu_kQ | u^\text{new})$, where $\mu_kQ$ is the mutation of the quiver (1.2) and $u^\text{new}$ is obtained from $u$ by replacing $u_k$ with

$$u^\text{new}_k = v_k^{-1}\left(\prod_i (u_k)^{Q(i,k)} + \prod_i (u_k)^{Q(k,i)}\right)$$

(0.5)

This is called the cluster transformation. Given a quiver $Q$, we call $(Q | \underline{x}) = (Q, (x_1, \ldots, x_n))$ an initial seed.

Definition 0.2. For a sequence of vertices $k = (k_1, \ldots, k_l) \in I^l$ and a vertex $i \in I$, we define rational functions $FZ_{k,i}(\underline{x})$ by

$$\mu_{k_l}(\cdots(\mu_1(Q | \underline{x})) \cdots) = (Q_k | (FZ_{k,i}(\underline{x}))).$$

The variables $x_{k,i,\pm}$ and $y_{k,i,\pm}$ on the left hand side of the equations does make sense since we have identified the two tori $T_{Q_k,\pm}$ and $T_{Q,\pm}$. 

4
In the case of a quiver of finite type, Caldero and Chapoton (CC06) described a composition of cluster transformations in terms of quiver Grassmannians of the original quiver. This result is generalized by many people (see the references in Pla for example). Finally, Derksen-Weyman-Zelevinsky and Plamondon (DWZ, Pla) provided the Caldero-Chapoton type formula for an arbitrary quiver without loops and oriented 2-cycles. In this paper, we provide an alternative proof of the Caldero-Chapoton type formula under the assumption that there is a potential $W$ such that the QP $(Q, W)$ is successively $f$-mutatable with respect to the sequence $k$ (1.3.2).

We identify $C(x_1, \ldots, x_n)$ with the fractional field of $T^{+}$. We will omit "+" in the notations.

**Theorem 0.3.** (Caldero-Chapoton type formula) We have

$$FZ_{k,i}(x) = x_k \cdot \left( \sum_v e \left( \text{Grass}(k; i, v) \right) \cdot y^{-v} \right) \quad (0.6)$$

where $(y^{-v}) = \prod_j (y_j)^{-v_j}$ and $y_j = \prod_i (x_i)^{Q(i,j)}$.

**Application to cluster algebras**

In [DWZ, Pla], they prove six conjectures given in [FZ07] for cluster algebras associated to quivers. In §8.3 and §8.4 we give alternative proofs for them under the assumption that the quiver with principal framing is successively $f$-mutatable.

Let $Q^{pf}$ be the following quiver:

- **vertices**: $I \sqcup I^*$ where $I^* = \{1^*, \ldots, n^*\}$,
- **arrows**: \{arrows in $Q\} \sqcup \{ i^* \rightarrow i \mid i \in I \}$.

This is called the quiver with the principal framing associated to $Q$. Let us use $\{X_i\}$ and $\{Y_i\}$ for generators of the tori associated to $Q^{pf}$.

**Definition 0.4.** (1) The $F$-polynomial associated to $(Q, W)$, $k$ and $i$ is the following:

$$F_{k,i}(y) := FZ_{k,i}(x)|_{X_i=1, X_i^* = y_i}.$$  

(2) The $g$-vector $g_{k,i} \in M_Q$ associated to $(Q, W)$, $k$ and $i$ is the element which is characterized by the following identity:

$$FZ_{k,i}(x) = x^{g_{k,i}} \cdot F_{k,i}(y^{-1})$$

where the last term is given by substituting $y_i^{-1}$ to $y_i$.

**Remark 0.5.** It is $y_i^{-1}$ in our notation what is denoted by $y_i$ in Fomin-Zelevinsky’s notation. We use this notation since $y_i$ corresponds to the simple module in our notation.

---

5Cluster algebras are associated not only with quivers without loops and oriented 2-cycles (equivalently, with skew-symmetric integer matrices) but also with skew-symmetric matrices.

6From the view points of applications to cluster algebras, the finite assumption is too strong. In this sense, our result on the Fomin-Zelevinsky conjectures is weaker than ones in [DWZ, Pla].
The potential $W$ of $Q$ can be taken as a potential of $Q^\text{pf}$. We assume that $(Q^\text{pf}, W)$ is successively 1-mutable with respect to the sequence $k$.

We will apply an argument similar to the one in §7 for $(Q^\text{pf}, W)$. Then we get descriptions of $g$-vectors and $F$-polynomials in terms of the 3-Calabi-Yau category:

| cluster algebra | DT theory |
|-----------------|-----------|
| $y$-variable $y_i$ | formal variable corresponding to the simple module $s_i$ |
| $x$-variable $x_i$ | formal variables corresponding to the projective module $P_i$ (or $\Gamma_i$) |
| $F$-polynomial | generating function of the Euler characteristics of the quiver Grassmannians |
| $g$-vector | $\phi^{-1}_k(\Gamma_{k,i}) \in M_Q = K_0(\text{per} \Gamma) \simeq \mathbb{Z}^f$ |
| $'g$-vector | $\phi_k([s_i]) \in L_Q \simeq \mathbb{Z}^f$ |
| $c$-vector | $\phi^{-1}_k(s_{k,i}) \in L_Q \simeq \mathbb{Z}^f$ |
| sign coherence of $'g$-vectors | $s_i \in T_k \subset A_k[1]$ or $s_i \in F_k \subset A_k$ |
| sign coherence of $c$-vectors | $s_{k,i} \in T_k[-1] \subset A[-1]$ or $s_{k,i} \in F_k \subset A$ |
| $g$-vectors determine $F$-vectors | Bridgeland stability on walls |

Contents

From §2 to §4, we study some categorical properties of the 3-dimensional Calabi-Yau category associated to a quiver with a potential. The statements of our main results appear in §5.

We prove the theorems using motivic Hall algebra, on which we give a brief review in §6. For the proof, first, we show in §7.1 some identities on the motivic Hall algebra using the results from §2 to §4. They are translated in §7.3 into the main results via the integration map.

Finally, we study quivers with principal framings to provide alternative proofs for the six conjectures given in [FZ07] (§8).

Comments

(1) Throughout this paper, we assume that all the potentials are finite. As we mentioned, from the viewpoints of applications to cluster algebras, we would like to remove the assumption. If we take an infinite potential, then the moduli spaces will not be schemes (or stacks) but formal schemes (or stacks). Once we construct a theory of the motivic Hall algebra in the formal setting, we can apply all the arguments in this paper.

(2) A typical example of a finite potential is a potential associated to a triangulated surface [LF09]. We will apply the results in this paper for a triangulated surface in [Naga].

7
(3) It is expected that there is a refinement of the DT theory, which is called the motivic DT theory ([KS, BBS]). Wall-crossing phenomena of the motivic DT theory has been studied in [KS, Nagc]. We hope to study quantum cluster algebras from the viewpoint of motivic DT theory in the future.

Acknowledgement

I would like to express my gratitude for all of the following mathematicians; Bernhard Keller who patiently explained many things about the cluster categories and the cluster algebras, indicated many stupid mistakes in the very preliminary version of this paper; Tom Bridgeland who showed me the preliminary version of his paper [Brib] and gave me a lot of helpful comments and encouragement. In particular, the proof of Theorem 3.4 is due to him; Pierre-Guy Plamondon who kindly explained the results in his PhD thesis [Pla]; Hiroaki Nakajima who explained me his results in [Naka] and encouraged me to promote the result of [KS]; Bernard Leclerc who recommended me to give alternative proofs for the conjectures in [FZ07]; Andrei Zelevinsky who gave me some comments on the preliminary version of this paper.

The first version of this paper was written while I have been visiting the University of Oxford. I am grateful to Dominic Joyce for the invitation and to the Mathematical Institute for hospitality.

The author is supported by the Grant-in-Aid for Research Activity Start-up (No. 22840023) and for Scientific Research (S) (No. 22224001).

1 Preliminary

1.1 QP, dga and Jacobi algebra

A quiver with a potential (QP, in short) is a pair \((Q, W)\) of a quiver \(Q\) and a potential \(W\), a linear combination of oriented cycles. We say that \(W\) (or \((Q, W)\)) is finite when \(W\) is a finite linear combination of oriented cycles. In this paper, we always assume that a QP is finite.

First, we define the derivation of the potential. For an arrow \(a\) and a oriented cycle \(a_1 \cdots a_t\), we put

\[
\partial_a(a_1 \cdots a_t) := \sum_i \delta_{a, a_i} a_{i+1} \cdots a_t a_1 \cdots a_{i-1}.
\]

For an arrow \(a\) and a potential \(W\), we define the derivation \(\partial_a W\) by the linear combination of the derivations of the oriented cycles.

For a QP \((Q, W)\), we define Ginzburg’s differential graded algebra \(\Gamma = \Gamma_{Q, W}\) as a graded algebra, \(\Gamma_{Q, W}\) is given by the path algebra \(\mathbb{C} \hat{Q}\) of the following graded quiver \(\hat{Q}\). The vertex set of \(\hat{Q}\) is the same as \(Q\) and the arrow set is the union of the following three sets:

- arrows in \(Q\) (degree 0),
- opposite arrow \(a^*\) for each arrow \(a\) in \(Q\) (degree \(-1\)),
- loop \(t_i\) at \(i\) for each vertex \(i\) in \(Q\) (degree \(-2\)).

We define the differential \(d = d_W\) of degree 1 on the path algebra \(\mathbb{C} \hat{Q}\) as follows:
• \( da = 0 \) for any arrow \( a \) in \( Q \)
• \( d(a^*) = \partial_a W \) for any arrow \( a \) in \( QC \)
• \( d(t_i) = e_i(\prod_{a}[a,a^*])e_i \) for any vertex \( i \) in \( Q \).

**Definition 1.1.**
(1) The differential graded algebra \( \Gamma_{Q,W} = (\hat{C}Q,d_W) \) is called the Ginzburg differential graded algebra (dga, in short).
(2) The algebra \( J = J_{Q,W} := H^0\Gamma_{Q,W} \) is called the Jacobi algebra.

The Jacobi algebra can be described as the quiver with the relations :
\[ J_{Q,W} = \mathbb{C}Q/\langle \partial_a W; a \in Q_1 \rangle. \]

### 1.2 Quiver mutation

In this paper, we always assume that a quiver has

- the vertex set \( I = \{1, \ldots, n\} \), and
- no loops and oriented 2-cycles.

For vertices \( i \) and \( j \) in \( I \), we put
\[ Q(i,j) = \sharp\{\text{arrows from } i \text{ to } j\}, \quad Q(i,j) = Q(i,j) - Q(j,i). \]

Note that the quiver \( Q \) is determined by the matrix \( \bar{Q}(i,j) \) under the assumption above.

For the vertex \( k \), we define the new quiver \( \mu_kQ \) as follows :

- First, we define a new quiver \( \mu_k^{\text{pre}}Q \) as follows F
  - For any subquiver \( u \xrightarrow{\alpha} k \xrightarrow{\beta} v \), we associate a new arrow \([\beta\alpha]: u \rightarrow v\).
  - replace any arrow \( a \) incident to the vertex \( k \) with an opposite arrow \( a^* \).
- Remove all oriented cycles of length 2 in \( \mu_k^{\text{pre}}Q \).

### 1.3 QP mutation

#### 1.3.1 Reduced part of a potential

Let \( \hat{\mathbb{C}}Q \) be the completion of \( \mathbb{C}Q \) with respect to path lengths.

A potential of \( Q \) is an element in \( \hat{\mathbb{C}}Q \) which is described as a linear combination of oriented cycles in \( Q \). We identify two potentials which are related via rotations of oriented cycles. A potential is said to be finite if it is an element in \( \mathbb{C}Q \).

Two QP \((Q,W)\) and \((Q',W')\) are said to be right equivalent, which is denoted by \((Q,W) \sim (Q',W')\), if there exists an algebra isomorphism \( \psi \) between \( \hat{\mathbb{C}}Q \) and \( \hat{\mathbb{C}}Q' \) so that \( \psi(W) = W' \). Two finite QP \((Q,W)\) and \((Q',W')\) are said to be right \( f \)-equivalent, which is denoted by \((Q,W) \overset{\mathbb{C}}{\sim} (Q',W')\), if there exists an algebra isomorphism \( \psi \) between \( \mathbb{C}Q \) and \( \mathbb{C}Q' \) so that \( \psi(W) = W' \).
A potential is said to be reduced if it has no oriented cycles of length less than 3, and said to be trivial if its Jacobi algebra is trivial. For quivers $Q$ and $Q'$ with the same vertex set, let $Q \cup Q'$ denote the quiver given by taking union the arrow sets. For QPs $(Q, W)$ and $(Q', W')$ with the same vertex set, we take $W$ and $W'$ as potentials of $Q \cup Q'$ and let $(Q, W) \oplus (Q', W')$ denote the new QP $(Q \cup Q', W + W')$.

For any QP $(Q, W)$, we have a right equivalence

$$(Q, W) \sim (Q, W)_{\text{red}} \oplus (Q, W)_{\text{triv}}$$

with reduced $W_{\text{red}}$ and trivial $W_{\text{triv}}$. Moreover, $(Q_{\text{red}}, W_{\text{red}})$ and $(Q_{\text{triv}}, W_{\text{triv}})$ are determined uniquely up to right equivalences. We call $(Q_{\text{red}}, W_{\text{red}})$ as the reduced part of $(Q, W)$.

A finite QP $(Q, W)$ is said to be $f$-reducible if we have a right $f$-equivalence

$$(Q, W) \sim (Q_{\text{red}}, W_{\text{red}}) \oplus (Q_{\text{triv}}, W_{\text{triv}})$$

with finite reduced $(Q_{\text{red}}, W_{\text{red}})$ and finite trivial $(Q_{\text{triv}}, W_{\text{triv}})$.

### 1.3.2 Potential mutation

For a QP $(Q, W)$ and a vertex $k$, we define the potential $\mu_k^{\text{pre}}W$ of the quiver $\mu_k^{\text{pre}}Q$ by

$$\mu_k^{\text{pre}}W := [W] + \Delta$$

where

- $[W]$ is the potential which is obtained from $W$ by replacing all the composition $u \xrightarrow{\alpha} k \xrightarrow{\beta} v$ with $[\beta \alpha]$, and
- $\Delta := \sum \alpha^* \beta^* [\beta \alpha]$.

The mutation $\mu_k(Q, W)$ of the QP $(Q, W)$ at $k$ is the reduced part $(\mu_k^{\text{pre}}Q, \mu_k^{\text{pre}}W)_{\text{red}}$ of $(\mu_k^{\text{pre}}Q, \mu_k^{\text{pre}}W)$.

**Definition 1.2.**

1. We say that a QP $(Q, W)$ is mutatable at $k$ if the underlying quiver of $\mu_k(Q, W)$ is $\mu_kQ$, the mutation of the quiver defined in §1.3.

2. We say that a finite QP $(Q, W)$ is $f$-mutable at $k$ if it is mutatable and $(\mu_k^{\text{pre}}Q, \mu_k^{\text{pre}}W)$ is $f$-reducible.

Let $k = (k_1, \ldots, k_l)$ be a sequence of vertices. A finite QP $(Q, W)$ is said to be successively $f$-mutable with respect to the sequence $k$ if

$$\mu_{k_{s-1}}(\cdots (\mu_{k_1}(Q, W)) \cdots)$$

is $f$-mutable at $k_s$. 

2 Derived categories

2.1 Categories
For a QP \((Q,W)\), we have the following triangulated categories:

\[ D_{\Gamma} : \text{the derived category of right dg-modules over Ginzburg dga } \Gamma, \]

\[ \text{per}\Gamma : \text{the smallest full subcategory of } D_{\Gamma} \text{ containing } \Gamma \text{ and closed under extensions, shifts and direct summands}, \]

\[ D_{\text{fd}} \Gamma : \text{the full subcategory of } D_{\Gamma} \text{ consisting of dg-modules with finite dimensional cohomologies.} \]

The triangulated categories \( D_{\Gamma} \) and \( D_{\text{fd}} \Gamma \) have the canonical t-structures whose cores are

\[ \text{Mod } J : \text{the category of finitely generated right modules over the (non-complete) Jacobi algebra, and} \]

\[ \text{mod } J : \text{the full subcategory of Mod } J \text{ consisting of finite dimensional modules respectively.} \]

For a vertex \( i \in I \), we have the following objects:

\[ s_i : \text{the simple } J \text{-module,} \]

\[ \Gamma_i := e_i \Gamma : \text{the } \Gamma \text{-module, which is a direct summand of } \Gamma, \text{ and} \]

\[ P_i := H^0_{\text{Mod }, J}(\Gamma_i) : \text{the projective indecomposable } J \text{-module.} \]

Here \( e_i \) is the idempotent.

2.2 Grothendieck groups
We put \( M = M_Q := K_0(\text{per}\Gamma) \) and \( L = L_Q := \mathbb{Z}^I \), where \( L \) is taken as the target of the map

\[ K_0(D_{\text{fd}} \Gamma) \to \mathbb{Z}^I = L \]

defined by \([E] \mapsto \dim(E)\). With a slight abuse of notations, we will write \([E] \in L\) instead of \(\dim(E)\).

We put \( M_\mathbb{R} = M_Q \otimes \mathbb{R} \) and \( L_\mathbb{R} = L_Q \otimes \mathbb{R} \). Let \( \chi \) denote the Euler pairing \( L \times L \to \mathbb{Z} \) given by

\[ \chi([E],[F]) = \sum_i (-1)^i \dim \text{Hom}(E,F[i]). \]

We put \( w_i := [\Gamma_i] \) and \( v_i := [s_i] \). The set \( \{w_i\} \) forms a basis of \( M \) and the set \( \{v_i\} \) forms a basis of \( L \). We extend \( \chi \) on \( L \otimes M \) by

\[ \chi(w_i,v_j) := \delta_{i,j}, \quad \chi(w,w') = 0 \]

for any \( w, w' \in M \). This gives \( M_{Q,\mathbb{R}} \simeq (L_{Q,\mathbb{R}})^* \).
2.3 Tori

Let \( \sigma \) be a sign; \( \sigma = \pm \). We define \( T_{Q,\sigma}^\nu \), \( T_{Q,\sigma} \) and \( T_{Q,\sigma} \) by

\[
T_{Q,\sigma}^\nu := \bigoplus_{w \in M} \mathbb{C} \cdot x_w^\nu, \quad T_{Q,\sigma} := \bigoplus_{w \in L} \mathbb{C} \cdot y_w^\nu, \quad T_{Q,\sigma} := T_{Q,\sigma}^\nu \otimes T_{Q,\sigma},
\]

with the following products:

\[
x_w^\nu \cdot x_{w'}^\nu = x_{\sigma w + w'}^\nu, \quad y_w^\nu \cdot y_{w'}^\nu = \sigma^{\chi(v,v')} y_{\sigma v + v'}^\nu, \quad x_{\sigma v}^\nu \cdot y_{\sigma v}^\nu = y_{\sigma v}^\nu \cdot x_{\sigma v}^\nu
\]

where we identify \( \pi \) and \( \pi' \) respectively. The kernel of \( \pi \) with the following products:

\[
x, y \mapsto x \cdot y = x y^\sigma.
\]

They are called the semiclassical limits of quantum torus, quantum double torus respectively. We define the surjective algebra homomorphism \( \pi_{\sigma} : T_{Q,\sigma} \twoheadrightarrow T_{Q,\sigma}^\nu \) by

\[
x_{i,\sigma} \otimes 1 \mapsto x_{i,\sigma}, \quad 1 \otimes y_{i,\sigma} \mapsto x_{i,\sigma}^{[\nu]}. \tag{2.1}
\]

The kernel of \( \pi_{\sigma} \) is generated by \( \{(x_{[\nu],\sigma} \otimes 1) - (1 \otimes y_{i,\sigma}) \mid i \in I\} \). We sometimes identify an element in \( T_{Q,\sigma} \) with its image in \( T_{Q,\sigma}^\nu \) under the composition

\[
T_{Q,\sigma} \hookrightarrow T_{Q,\sigma} \xrightarrow{\pi_{\sigma}} T_{Q,\sigma}^\nu.
\]

Let \( \Sigma \) denote the automorphism of the tori given by

\[
\Sigma(x_w^\nu) = x_{\sigma w}^\nu, \quad \Sigma(y_w^\nu) = y_{\sigma w}^\nu.
\]

2.4 Mutation and derived equivalence

2.4.1 Derived equivalence

Let \( (Q,W) \) be a finite QP which is \( f \)-mutable at a vertex \( k \). Let \( \mu_k \Gamma \) be the Ginzburg dga associated to the mutation \( \mu_k(Q,W) \).

**Theorem 2.1** ([KY] Theorem 3.2), ([Kelb] §7.6). There exist equivalences of triangulated categories

\[
\Phi_{k,+}, \Phi_{k,-} : \mathcal{D} \Gamma \xrightarrow{\sim} \mathcal{D} \mu_k \Gamma
\]

such that

- \( \Phi_{k,\pm}^{-1}(\Gamma'_i) = \Gamma_i \), for \( i \neq k \), and

- \( \Phi_{k,+}^{-1}(\Gamma'_k) \) and \( \Phi_{k,-}^{-1}(\Gamma'_k) \) are involved in the following triangles:

\[
\begin{align*}
\Phi_{k,+}^{-1}(\Gamma'_k)[-1] & \to \bigoplus_j \Gamma^{(Q)(k,j)}_j \Rightarrow \Gamma_k & \Rightarrow & \Phi_{k,+}^{-1}(\Gamma'_k), \\
\Phi_{k,-}^{-1}(\Gamma'_k) & \to \Gamma_k & \Rightarrow & \bigoplus_j \Gamma^{(Q)(j,k)}_j \Rightarrow \Phi_{k,-}^{-1}(\Gamma'_k)[1]
\end{align*}
\]

\(^7\)Since Spec of them are algebraic tori, we call them tori with a slight abuse.
where $\Gamma'_i$ is the direct summand of $\mu_k\Gamma$. Moreover, $\Phi_{k,\pm}$ restricts to equivalences from $\text{per}\Gamma$ to $\text{per}(\mu_k\Gamma)$ and from $D^{\text{fd}}\Gamma$ to $D^{\text{fd}}(\mu_k\Gamma)$.

**Remark 2.2.** It is $\Phi_{k,1}^{-1}$ that is studied in [KY, Theorem 3.2].

The equivalences induce isomorphisms
\[
\phi_{k,\pm} : M_Q \simto M_{\mu_k Q}
\]
and
\[
\phi_{k,\pm} : L_Q \simto L_{\mu_k Q}.
\]
By the triangles in Theorem 2.1 we have
\[
\phi_{k,\pm}^{-1}([\Gamma'_i]) = \begin{cases} [\Gamma_i] & \text{if } i \neq k, \\ -[\Gamma_k] + \sum_j Q(k, j)[\Gamma_j] & \text{if } i = k, \end{cases}
\]

\[
\phi_{k,\pm}^{-1}([\Gamma'_i]) = \begin{cases} [\Gamma_i] & \text{if } i \neq k, \\ -[\Gamma_i] + \sum_j Q(j, k)[\Gamma_j] & \text{if } i = k. \end{cases}
\]

(2.2)

in $M_Q$. Since $\phi_{k,\pm}$ preserves $\chi$ we have
\[
\phi_{k,\pm}^{-1}([s'_i]) = \begin{cases} [s_i] + Q(k, i)[s_k] & \text{if } i \neq k, \\ -[s_k] & \text{if } i = k, \end{cases}
\]

\[
\phi_{k,\pm}^{-1}([s'_i]) = \begin{cases} [s_i] + Q(i, k)[s_k] & \text{if } i \neq k, \\ -[s_k] & \text{if } i = k. \end{cases}
\]

(2.3)
in $L_Q$. Note that $\phi_{k,\pm}$ also induce isomorphisms between $T_{Q,\sigma}$ and $T_{\mu_k Q,\sigma}$. We sometimes identify them with each other and write simply $T_{\sigma}$ since we do not want to specify a choice of a quiver.

### 3 Tilting of t-structures

#### 3.1 Torsion pair and tilting

Let $D$ be a triangulated category and $A$ be the core of a t-structure.

**Definition 3.1.** A pair $(T, F)$ of full subcategories of $A$ is called a torsion pair if the following conditions are satisfied:

**(TP1)** for any $T \in T$ and any $F \in F$, we have $\text{Hom}(T, F) = 0$,

**(TP2)** for any $X \in A$, there exists an exact sequence
\[
0 \to T \to X \to F \to 0
\]

with $T \in T$ and $F \in F$.

We sometimes illustrate the torsion pair as in Figure 1. In the figure, we have no non-trivial morphism from an object on left to an object on right.

Given a torsion pair $(T, F)$, let $D^{(F, T[-1])} \leq -1$ denote the full subcategory of $D$ consisting of objects $E$ which satisfy
\[
H^i_A(E) \begin{cases} \in T & i = 0, \\ = 0 & i \geq 1, \end{cases}
\]
Figure 1: Torsion pair

and let $D_{\geq 0}^{(F,T[-1])}$ denote the full subcategory of $D$ consisting of objects $E$ which satisfy

$$H^i_A(E) \begin{cases} \in F & i = 0, \\ = 0 & i \leq -1. \end{cases}$$

Then the pair of full subcategories

$$(D_{\leq -1}^{(F,T[-1])}, D_{\geq 0}^{(F,T[-1])})$$

gives a t-structure of $D$ (see Figure 2). Let

$$A^{(F,T[-1])} := D_{\leq -1}^{(F,T[-1])} \cap D_{\geq 0}^{(F,T[-1])}$$

be the heart of the t-structure. That is, $A^{(F,T[-1])}$ is the full subcategory of $D$ consisting of objects $E$ which satisfy

$$H^i_A(E) \begin{cases} \in F & i = 0, \\ \in T & i = 1, \\ = 0 & i \neq 0,1. \end{cases}$$

3.2 Composition of tilting

Let $(T, F)$ be a torsion pair of $A$ and we put $A' := A^{(F,T[-1])}$. Let $(T', F')$ be a torsion pair of $A'$ such that $T' \subset F$. We put $A'' = (A')^{(F',T'[−1])}$.
Let $\mathcal{T}''$ denote the full subcategory of $\mathcal{A}$ consisting of $X$ with $F_X \in \mathcal{T}'$ where $F_X \in \mathcal{F}$ is the quotient object of $X$ associated to the exact sequence (TP2) for $(\mathcal{T}, \mathcal{F})$. Let $\mathcal{F}''$ denote the full subcategory of $\mathcal{F}$ consisting of $Y$ with $T_Y = 0$ where $T_Y \in \mathcal{T}'$ is the subobject of $Y$ associated to the exact sequence (TP2) for $(\mathcal{T}', \mathcal{F}')$. (See Figure 3.) We can easily verify the following lemma.

**Lemma 3.2.** The pair of the full subcategories $(\mathcal{T}'', \mathcal{F}'')$ gives a torsion pair of $\mathcal{A}$ and

$\mathcal{A}'' = \mathcal{A}(\mathcal{F}'', \mathcal{T}'[-1])$

On the other hand, assume that $(\mathcal{T}', \mathcal{F}')$ is a torsion pair of $\mathcal{A}'$ such that $\mathcal{F}' \subset \mathcal{T}[-1]$. Let $\mathcal{F}''$ denote the full subcategory of $\mathcal{A}$ consisting of $X$ with $T_Y \in \mathcal{F}'[1]$ where $T_Y \in \mathcal{T}$ is the subobject of $Y$ associated to the exact sequence (TP2) for $(\mathcal{T}, \mathcal{F})$. Let $\mathcal{T}''$ denote the full subcategory of $\mathcal{T}$ consisting of $X$ with $F_X = 0$ where $F_X \in \mathcal{F}'[1]$ is the quotient object of $X$ associated to the exact sequence (TP2) for $(\mathcal{T}'[1], \mathcal{F}'[1])$ (see Figure 4). We put $\mathcal{A}'' := \mathcal{A}'(\mathcal{F}'[1], \mathcal{T}')$. We can also verify the following lemma.

**Figure 3: Composition of tilting (Lemma 3.2)**

**Figure 4: Composition of tilting (Lemma 3.3)**
Lemma 3.3. The pair of the full subcategories \((T'', F'')\) gives a torsion pair of \(A\) and 
\[ A' := A(T'', T'[-1]) \]

3.3 Mutation and tilting

Let \(S_k\) be the full subcategory consisting of \(J_{Q,W}\)-modules supported on the vertex \(k\). We put 
\[ (S_k)^\perp := \{ E \in \text{Mod}_{J_{Q,W}} | \text{Hom}(s_k, E) = 0 \} \]
\[ \perp(S_k) := \{ E \in \text{Mod}_{J_{Q,W}} | \text{Hom}(E, s_k) = 0 \} \]

Then both \((S_k, (S_k)^\perp)\) and \((\perp(S_k), S_k)\) give torsion pairs of \(\text{Mod}_{J_{Q,W}}\). It is shown in [KY, Corollary 5.5] that the derived equivalences associated to a mutation are given by tilting with respect to these torsion pairs:
\[ \Phi_{k,+}^{-1}(\text{Mod}_{J_{\mu_k(Q,W)}}) = (\text{Mod}_{J_{Q,W}})(S_k, (S_k)^\perp) \]
\[ \Phi_{k,-}^{-1}(\text{Mod}_{J_{\mu_k(Q,W)}}) = (\text{Mod}_{J_{Q,W}})((\perp(S_k), S_k)^\perp) \]

3.4 Composition of mutations and tilting

The proof of the following theorem is due to Tom Bridgeland. We put \(\bar{A} := \text{Mod}_{J_{Q,W}}\).

Theorem 3.4. There exists a unique sequence \(\varepsilon(1), \ldots, \varepsilon(l)\) of signs which satisfies the following conditions; We put 
\[ \bar{A}_k := \Phi_{k, \varepsilon(1)}^{-1}(\text{Mod}_{J_{\mu_k(Q,W)}}) \]
and 
\[ \bar{A}_k := \Phi_{k, \varepsilon(l)}^{-1}(\text{Mod}_{J_{\mu_k(Q,W)}}) \]

Then

(A) there exists a torsion pair \((\bar{T}_k, \bar{F}_k)\) of \(\bar{A}\) such that 
\[ \bar{A}(\bar{T}_k, \bar{T}_k[-1]) = \bar{A}_k \]

(B) \(\Phi_{k,-}^{-1}(s_{k,i}) \in \bar{F}_k\) or \(\Phi_{k,+}^{-1}(s_{k,i}) \in \bar{T}_k[-1]\) for any \(i \in Q_0\) where \(s_{k,i}\) is the simple \(J_{\mu_k(Q,W)}\)-module.

Proof. We prove the claim by induction with respect to the length \(l\) of the sequence. First of all, (A) is hold if we take \(\varepsilon(1) = +\) by (3.1).

(A) \(\implies\) (B) : 
Since \((\bar{F}_k, \bar{T}_k[-1])\) give a torsion pair for \(\bar{A}_k\), an exact sequence is associated to \(\Phi_{k,-}^{-1}(s_{k,i})\). Because \(\Phi_{k,-}^{-1}(s_{k,i})\) is simple in \(\bar{A}_k\), we have 
\[ \Phi_{k,-}^{-1}(s_{k,i}) \in \bar{F}_k \]
or 
\[ \Phi_{k,+}^{-1}(s_{k,i}) \in \bar{T}_k[-1] \]
(B_l) \Rightarrow (A_{l+1}) :

We define \( \varepsilon(l) \) by

\[
\varepsilon(l) = \begin{cases} 
+ & \text{if } \Phi^{-1}_{k}(s_{k,i}) \in F_{k}, \\
- & \text{if } \Phi^{-1}_{k}(s_{k,i}) \in T_{k}[-1].
\end{cases}
\]

Then the claim follows Lemma 3.2 and Lemma 3.3. \( \square \)

Remark 3.5. A similar statement has been shown in [PL, Theorem 2.15].

For \( 1 \leq r \leq l \), let \( k^{(r)} \) denote the truncated sequence \((k_{1}, \ldots, k_{r})\). For \( i \in I \), we define \( s^{(r)}_{i} \in A \)

\[
s^{(r)}_{i} := \begin{cases} 
\Phi^{-1}_{k^{(r)}}(s_{k^{(r)},i}) & \text{if } \Phi^{-1}_{k^{(r)}}(s_{k^{(r)},i}) \in F_{k^{(r)}}, \\
\Phi^{-1}_{k^{(r)}}(s_{k^{(r)},i})[1] & \text{if } \Phi^{-1}_{k^{(r)}}(s_{k^{(r)},i}) \in T_{k^{(r)}}[-1].
\end{cases}
\]

We put \( s^{(r)} := s^{(r)}_{k^{(r)}} \).

The canonical t-structure of \( D\Gamma \) induces a t-structure of \( D_{fd}\Gamma \) whose core is \( A := \text{mod}(J_{Q,W}) \). Since \( s^{(r)} \in A \) for any \( r \), we have \( T_{k} \in A \). We put

\[
A_{k} := \Phi_{k}^{-1}(\text{mod}J_{\mu_{k}(Q,W)}), \quad T_{k} := T_{k}, \quad F_{k} := F_{k} \cap A.
\]

Then we can verify the following :

Corollary 3.6. The pair of the full subcategories \((T_{k}, F_{k})\) gives a torsion pair of \( A \) and

\[
A_{k} = A(F_{k}, T_{k}[-1]).
\]

Figure 5: Composition of mutation and tilting

4 Stability condition on \( D^{fd}\Gamma \)

In this section, we study the space of stability conditions on \( D^{fd}\Gamma \). For a subcategory \( C \subset D^{fd}\Gamma \), let \( C_{C} \subset L_{A} \) be the minimal cone containing all the classes of elements in \( C \) and we define its dual cone \( C_{C}^{*} \) by

\[
C_{C}^{*} := \{ \theta \in (L_{A})^{*} \mid M_{R} \mid \langle \theta, \nu \rangle > 0 \text{ for any } \nu \in C_{C} \}.
\]

Throughout this section, we fix an element \( \delta \in C_{A}^{*} \). For \( \theta \in (L_{A})^{*} = M_{R} \), let

\[
Z_{\theta} : L \to C
\]
denote the group homomorphism given by \( Z_{\theta} := (-\delta + \sqrt{-1} \theta, \bullet) \).
4.1 Embedding of $M_{\mathbb{R}}$

If $\theta \in C^*_{\mathbb{A}}$, the pair $\zeta(\theta) := (\mathcal{A}, Z_\theta)$ gives a Bridgeland’s stability condition on $\mathcal{D}^{\text{fd}}\Gamma$. This gives an embedding

$$\zeta: C^*_{\mathbb{A}} \hookrightarrow \text{Stab}(\mathcal{D}^{\text{fd}}\Gamma)$$

where the right hand side is the space of Bridgeland stability conditions on $\mathcal{D}^{\text{fd}}\Gamma$. We will extend this to an embedding of $(L_{\mathbb{R}})^* = M_{\mathbb{R}}$.

For two real numbers $t$ and $\phi$, we define $t^*\phi \in \mathbb{R}$ so that

$$\tan((t^*\phi)\pi) = \tan(\phi\pi) + t, \quad 0^*\phi = \phi$$

and so that the map $(t, \phi) \mapsto t^*\phi$ is continuous. For $\theta \in C^*$, let $\mathcal{P}_\theta$ the slicing of $\mathcal{D}^{\text{fd}}\Gamma$ corresponding to the stability condition $\zeta(\theta)$ ([Bri07] Definition 5.1 and Proposition 5.3). That is, $\mathcal{P}_\theta(\phi)$ is the full subcategory of semistable objects with phase $\phi \in \mathbb{R}$ with respect to the stability condition $\zeta(\theta)$. We define the slicing $t^*\mathcal{P}_\theta$ by

$$t^*\mathcal{P}_\theta(\phi) := \mathcal{P}_\theta(t^*\phi).$$

Then the pair $(t^*\mathcal{P}_\theta, Z_{\theta-t\delta})$ gives a stability condition (Figure 6). We define the map

$$\zeta: (L_{\mathbb{R}})^* = M_{\mathbb{R}} \rightarrow \text{Stab}(\mathcal{D}^{\text{fd}}\Gamma).$$

by

$$\zeta(\theta - t\delta) := (t^*\mathcal{P}_\theta, Z_{\theta-t\delta})$$

for any $\theta \in C^*_A$ and $t \in \mathbb{R}$. We can verify that this is well-defined and injective.

4.2 T-structures

In this subsection, we describe the t-structures corresponding to some stability conditions in $\zeta(M_{\mathbb{R}})$. For a stability condition $\zeta$, let $\mathcal{A}_\zeta$ denote the core of the t-structure corresponding to $\zeta$, i.e. the full subcategory of objects whose HN factors have phases in $[0, 1)$.

**Proposition 4.1.** For $\theta \in C^*_A$, we have $\mathcal{A}_{\zeta(\theta)} = \mathcal{A}_k$. 

18
Proof. We will prove by induction with respect to the length $l$ of the sequence $k$. For $1 \leq r \leq l$ we put $A^{(r)} := A_{k^{(r)}}$, where $k^{(r)}$ is the truncated sequence.

For $i \in I$, let $W_{i}^{(r-1)}$ denote the hyperplane which is perpendicular to $s_{i}^{(r)}$:

$$W_{i}^{(r-1)} := \left\{ \theta \left| \langle \theta, [s_{i}^{(r)}] \rangle = 0 \right. \right\}.$$

Note that the boundary of $C^{*}_{A^{(r-1)}}$ is contained in the union of $W_{i}^{(r-1)}$'s.

Assume that $A_{\zeta(\theta)} = A^{(r-1)}$ for $\theta \in C^{*}_{A^{(r-1)}}$. Take $\theta' \in C^{*}_{A^{(r)}}$ which is sufficiently close to the hyperplane $W_{k_{r}}^{(r-1)} = W_{k_{r}}^{(r)}$ and which is sufficiently far from the other hyperplanes. It is enough to show that $A_{\zeta(\theta')} = A^{(r)}$.

In the case of $\varepsilon(r) = +$, we have

$$\text{Re}Z_{\theta}(s(r)), \text{Im}Z_{\phi}(s(r)) < 0, \quad \text{Im}Z_{\theta}(s(r)) > 0, \quad \text{Im}Z_{\phi}(s(r)) < 0$$

(see Figure 7). So the core $A_{\zeta(\theta')}$ is given by tilting the core $A_{\zeta(\theta)}$ with respect to the torsion pair

$$\left( S(r), (S(r))^{\perp} \right)$$

where

$$S(r) := \left\{ (s^{(r)})^{\perp n} \left| n \geq 0 \right. \right\}.$$

By (3.2), we get $A_{\zeta(\theta')} = A^{(r)}$. We can see in the case of $\varepsilon(r) = -$ in the same way. 

**Theorem 4.2.** Assume we have $C_{k} = C_{k'}$. Then, the equivalence $\Phi_{k'} \circ \Phi_{k}^{-1}$ induces an equivalence from $\text{mod}J_{k}$ to $\text{mod}J_{k'}$. Moreover, there is a unique permutation $\kappa \in S_{I}$ of $I$ such that

$$\Phi_{k'} \circ \Phi_{k}^{-1}(s_{k,i}) = s_{k',\kappa(i)}$$

**Proof.** The equivalence for $\text{mod}J_{k}$ is a consequence of Proposition 4.1. The permutation is induced by the description of the boundary of the chamber. 

5 **Statements**

5.1 **Quiver Grassmannian**

Let $\Gamma_{k,i}$ denote the direct summand of $\Gamma_{k}$ and $P_{k,i}$ denote the projective indecomposable $J_{k}$-module. We put

$$R_{k,i} := H^{1}_{A}(\Phi_{k}^{-1}(\Gamma_{k,i})) = H^{1}_{A}(\Phi_{k}^{-1}(P_{k,i})) \in T_{k} \subset A.$$
Definition 5.1. For \( v \in L \), let \( \text{Grass}(k; i, v) \) be the moduli scheme which parametrizes elements \( V \) in \( A \) equipped with surjections from \( R_{k,i} \) such that \([V] = v\):

\[
\text{Grass}(k; i, v) := \{ R_{k,i} \twoheadrightarrow V \mid V \in A, [V] = v \}.
\]

We call \( \text{Grass}(k; i, v) \) as a quiver Grassmannian.

Remark 5.2. We can construct the moduli scheme as a GIT quotient (see [Nagb, §5.1]).

Let \( M_A \) be the moduli stack of objects in \( A \) and \( \nu_{M_A} \) be the Behrend function on it ([Beh09]). We define

\[
e_+(\text{Grass}(k; i, v)) := e(\text{Grass}(k; i, v)),
\]

\[
e_-(\text{Grass}(k; i, v)) := \int_{\text{Grass}(k; i, v)} \pi^*(\nu_{M_A}) \cdot de = \sum_{n \in \mathbb{Z}} n \cdot e(\pi^*(\nu_{M_A})^{-1}(n)),
\]

where \( \pi : \text{Grass}(k; i, v) \to M_A \) is the forgetful morphism and \( e(-) \) represents the topological Euler characteristics.

5.2 On non-commutative Donaldson-Thomas invariants

5.2.1 Non-commutative Donaldson-Thomas invariants

For a vertex \( i \in I \) and an element \( v \in L \), let \( \text{Hilb}_J(i; v) \) be the moduli scheme which parametrizes elements in \( V \in \text{Mod}_J \) equipped with a surjection from \( P_i \) such that \([V] = v\):

\[
\text{Hilb}_J(i; v) := \{ P_i \twoheadrightarrow V \mid V \in A, [V] = v \}.
\]

Definition 5.3 ([Sze08]). We define invariants by

\[
\text{DT}_{J,+}(i; v) := e(\text{Hilb}_J(i; v)),
\]

\[
\text{DT}_{J,-}(i; v) := \int_{\text{Hilb}_J(i; v)} \pi^*(\nu_{M_A}) \cdot de = \sum_{n \in \mathbb{Z}} n \cdot e(\pi^*(\nu_{M_A})^{-1}(n)),
\]

where \( \pi : \text{Hilb}_J(i; v) \to M_A \) is the forgetful morphism.

Remark 5.4. The non-commutative Donaldson-Thomas invariants in [Sze08] are defined using the Behrend function on \( \text{Hilb}_J(i; v) \):

\[
\text{DT}_{J,J \text{Sze}}(i; v) := \int_{\text{Hilb}_J(i; v)} \nu_{\text{Hilb}_J(i; v)} \cdot de := \sum_{n \in \mathbb{Z}} n \cdot e(\nu_{\text{Hilb}_J(i; v)}^{-1}(n)).
\]

We have \( \pi^*(\nu_{M_A}) = (-1)^{v_i} \cdot \nu_{\text{Hilb}_J(i; v)} \) and

\[
\text{DT}_{J,J \text{Sze}}(i; v) = (-1)^{v_i} \cdot \text{DT}_{J,-}(i; v).
\]

We define generating functions by

\[
Z_{J,\sigma} := \sum_v \text{DT}_{J,\sigma}(i; v) \cdot y_v^\sigma.
\]

20
5.2.2 Torus automorphism via ncDT invariants

For a full subcategory $C \subset D^\text{fd}_\Gamma$, we define $\hat{T}_C,\sigma$ and $\hat{T}_C,\sigma$ by

$$\hat{T}_C,\sigma := \left( \prod_{v \in L \cap C} C \cdot y_v^\sigma \right) \oplus \left( \bigoplus_{v \in L \setminus C} C \cdot y_v^\sigma \right),$$

$\hat{T}_{\tilde{C},\sigma} := T_{\tilde{C},\sigma} \otimes \hat{T}_C,\sigma$

where $C \subset L_R$ is the minimal cone which contains all the classes of elements in $C$. They are called the completions with respect to $C$. If $C$ is a subcategory of a core of a $t$-structure, then the products extend to these completions. Moreover, if $C' \subset C$ then the completions with respect to $C'$ give subalgebras of the ones with respect to $C$. If an automorphism of the completion with respect to $C'$ lifts to the one for $C$, we use the same symbol as the original automorphism for the lift. Note that $Z_i^J,\sigma$ gives an elements in $\hat{T}_A,\sigma$.

**Definition 5.5.** We define torus automorphisms

$$DT_J,\sigma : \hat{T}_A,\sigma \sim \to \hat{T}_A,\sigma$$

by

$$DT_J,\sigma(x_i,\sigma) := x_i,\sigma \cdot Z_i^J,\sigma, \quad DT_J,\sigma(y_i,\sigma) := y_i,\sigma \cdot \prod_j (Z_j^J,\sigma)^{Q(j,i)}.$$

5.2.3 Transformation formula of ncDT invariants

**Definition 5.6.** We define torus automorphisms

$$\text{Ad}_{T_k[-1],\sigma} : T_\sigma \sim \to T_\sigma$$

by

$$\text{Ad}_{T_k[-1],\sigma}(x_{k,i},\sigma) := x_{k,i},\sigma \cdot \left( \sum_v e_{\sigma}(\text{Grass}(k;i,v) \cdot y_v^{-v}) \right), \quad \text{Ad}_{T_k[-1],\sigma}(y_{k,i},\sigma) := y_{k,i},\sigma \cdot \prod_j \left( \sum_v e_{\sigma}(\text{Grass}(k;j,v) \cdot y_v^{-v}) \right)^{Q(j,i)}.$$

They lift to the completions with respect to $A_k$. We also define $\text{Ad}_{T_k,\sigma}$ by

$$\text{Ad}_{T_k,\sigma} := \Sigma \circ \text{Ad}_{T_k[-1],\sigma} \circ \Sigma$$

which lift to the completions with respect to $A_k$. (See (0.3) for the definition of $\Sigma$.)

**Theorem 5.7.** The composition

$$\text{Ad}_{T_k,\sigma}^{-1} \circ DT_J,\sigma$$

preserves $\hat{T}_{F_k,\sigma}$ and lifts to the automorphism of $\hat{T}_{A_k,\sigma}$. Moreover, we have the following identity of automorphisms of $\hat{T}_{A_k,\sigma}$:

$$DT_J,\sigma = \text{Ad}_{T_k,\sigma}^{-1} \circ DT_J,\sigma \circ \text{Ad}_{T_k[-1],\sigma}.$$
5.3 Caldero-Chapoton formula

In this subsection, we put $\sigma = +$ and use notations without “+”. We identify $C(x_1, \ldots, x_n)$ with the fractional field of $TQ$.

**Theorem 5.8.** We have

$$FZ_{k,i}(x) = x_{k,i} \cdot \left( \sum_{v} e\left( \text{Grass}(k, i, v) \right) \cdot y^{-v} \right).$$  (5.3)

where $(y)^{-v} = \prod_j (y_j)^{-v_j}$ and $y_j = \prod_i (x_{i,j})^{Q(i,j)}$

**Example 5.9.** If we take a sequence $k = (k)$ of length 1, then we have

$$R_{(k),i} = \begin{cases} 0 & i \neq k, \\ s_k & i = k. \end{cases}$$

Hence we have

$$FZ_{i,k}(x) = \begin{cases} x'_{i} & i \neq k, \\ x'_k(1 + (y_k)^{-1}) & i = k, \end{cases}$$  (5.4)

where $y_k = \prod_j (x_{j})^{Q(j,k)}$, $x'_i := x^{[\Gamma_i]}$ and $\Gamma_i$ is the direct summand of $\mu_k \Gamma$. Note that by (2.2) we have

$$x'_i = x_i \ (i \neq k), \quad x'_k = (x_k)^{-1} \prod_j (x_j)^{Q(j,k)},$$

Substituting these for (5.4), we get the cluster transformation (0.5).

6 Review: Motivic Hall algebra

6.1 Motivic Hall algebra and its limit

6.1.1 Relative Grothendieck ring of stacks

For an algebraic stack $S$, let $\text{St}/S$ denote the category whose objects are finite type stacks $X$ over $C$ equipped with a morphism to $S$.

A morphism of stacks $f: \rightarrow Y$ is said to be a **geometric bijection** if it is representable and the induced functor on groupoids of $C$-valued points

$$f(\mathbb{C}): X(\mathbb{C}) \rightarrow Y(\mathbb{C})$$

is an equivalence of categories ([Brih Definition 3.1]).

A morphism of stacks $f: \rightarrow Y$ is said to be a **Zariski fibration** if its pullback to any scheme is a Zariski fibration of schemes ([Brih Definition 3.3]).

We define $K(\text{St}/S)$ by the free Abelian group spanned by isomorphism classes of $\text{St}/S$ modulo the following relations:

1. $[X_1 \sqcup X_2, f_1 \sqcup f_2] = [X_1, f_1 \rightarrow S] + [X_2, f_2 \rightarrow S]$,
2. $[X_1, f_1 \rightarrow S] = [X_2, f_2 \rightarrow S]$ if there is a geometric bijection $g: X_1 \rightarrow X_2$ with $f_1 = f_2 \circ g,$
(3) \([X_1 \xrightarrow{f_1} S] = [X_2 \xrightarrow{f_2} S]\) if there is a factorisations \(f_i = g \circ h_i\) such that \(h_i: X_i \to Y\) are Zariski fibrations with the same fibres \((\text{Brib Definition 3.6})\). We call \(K(\text{St}/S)\) as the relative Grothendieck ring of stacks over \(S\).

A morphism of stacks \(\psi: T \to S\) induces a map
\[
\psi_*: K(\text{St}/T) \to K(\text{St}/S)
\]
sending \([g: Y \to T]\) to \([\psi \circ g: X \to S]\). If \(\psi\) is of finite type it also induces a map
\[
\psi^*: K(\text{St}/S) \to K(\text{St}/T)
\]
sending \([f: X \to S]\) to the map \([g: Y \to T]\) in the following Cartesian diagram:
\[
\begin{array}{ccc}
Y & \xrightarrow{g} & T \\
\downarrow & & \downarrow \\
X & \xrightarrow{f} & S
\end{array}
\]

6.1.2 Motivic Hall algebra

Let \(M_A\) be the moduli stack of all objects in \(A = \text{mod} J\) and \(M_A^{(2)}\) be the moduli stack of all exact sequences in \(A\). Let \(p_\varepsilon: M_A^{(2)} \to M_A\) \((\varepsilon = 1, 2, 3)\) be the morphism given by taking \(\varepsilon\)-th terms of exact sequences. Then, \(p_2\) is of finite type. Using the diagram
\[
\begin{array}{ccc}
M_A^{(2)} & \xrightarrow{p_2} & M_A \\
p_1 \times p_3 \\
\downarrow & & \downarrow \\
M_A \times M_A
\end{array}
\]
we define a product \(*\) on \(K(\text{St}/M_A)\) by
\[
*: (p_2)_*(p_1 \times p_3)^*: K(\text{St}/M_A) \otimes K(\text{St}/M_A) \to K(\text{St}/M_A). \quad (6.1)
\]
We put \(MH(A) := K(\text{St}/M_A)\). The algebra \((MH(A), *)\) is called the motivic Hall algebra of the Abelian category \(A\).

Theorem 6.1 \((\text{Joy07}, \text{Brib Theorem 4.1})\). The motivic Hall algebra \((MH(A), *)\) is associative.

Remark 6.2. The 3-Calabi-Yau property of the category \(A\) is not necessary for this theorem.

6.1.3 Semi-classical limit of the motivic Hall algebra

Let \(MH_0(A) \subset MH(A)\) be the \(K(\text{Var}/\mathbb{C})[[L^{-1}]]\)-submodule generated by classes
\[
[X \xrightarrow{f} M_A]
\]
with \(X\) a variety.
Theorem 6.3 ([Brib] Theorem 5.2). (1) \( \text{MH}_0(\mathcal{A}) \subset \text{MH}(\mathcal{A}) \) is a subring.

(2) The product induced on the quotient

\[ \text{MH}_{sc}(\mathcal{A}) := \text{MH}_0(\mathcal{A})/(L - 1)\text{MH}_0(\mathcal{A}) \]

is commutative \( K(\text{Var}/\mathbb{C}) \)-algebra.

We define a Poisson bracket \( \{ - , - \} \) on \( \text{MH}_{sc}(\mathcal{A}) \) by

\[ \{ f, g \} = \frac{f \ast g - g \ast f}{L - 1} \mod (L - 1). \]

6.1.4 Completion of the motivic Hall algebra

Note that the moduli stack has the canonical decomposition

\[ \mathcal{M}_\mathcal{A} = \bigsqcup_{v \in \mathcal{C} \cap L} \mathcal{M}_\mathcal{A}(v). \]

We put

\[ \widehat{\text{MH}}(\mathcal{A}) := \prod_{v \in \mathcal{C} \cap L} K(\text{St}/\mathcal{M}_\mathcal{A}(v)), \]

then the \( \ast \)-product canonically extends to \( \widehat{\text{MH}}(\mathcal{A}) \).

Let \( \mathcal{C} \subset \mathcal{A} \) be an extension closed full subcategory. Assume that the moduli stack \( \mathcal{M}_\mathcal{C} \subset \mathcal{M}_\mathcal{A} \) of objects in \( \mathcal{C} \) is algebraic. Let \( \text{MH}(\mathcal{C}) \) denote the subalgebra consisting of the elements \([ f : \mathcal{X} \to \mathcal{M}_\mathcal{A}] \) such that \( f \) factors through \( \mathcal{M}_\mathcal{C} \subset \mathcal{M}_\mathcal{A} \). We put

\[ \widehat{\text{MH}}(\mathcal{C}) := \prod_{v \in \mathcal{C} \cap L} \left( \text{MH}(\mathcal{C}) \cap K(\text{St}/\mathcal{M}_\mathcal{A}(v)) \right). \]

We define \( \widehat{\text{MH}}_0(\mathcal{A}), \widehat{\text{MH}}_{sc}(\mathcal{A}), \widehat{\text{MH}}_0(\mathcal{C}) \) and \( \widehat{\text{MH}}_{sc}(\mathcal{C}) \) in the same way.

6.2 Quantum torus and integration map

6.2.1 Quantum torus and semi-classical limit

The quantum torus, dual quantum torus and double quantum torus for \( \mathcal{D}^{\text{fd}}\Gamma \) is the \( \mathbb{C}(t) \)-vector spaces

\[ \text{QT} := \sum_{v \in L} \mathbb{C}(t) \cdot y^v, \quad \text{QT}^\vee := \sum_{w \in M} \mathbb{C}(t) \cdot x^w, \quad \text{QT}^\square := \text{QT}^\vee \otimes \text{QT} \]

with the following product structure:

\[ y^v \cdot y^{v'} = t^{(v,v')} y^{v+v'}, \quad x^w \cdot x^{w'} = x^{w+w'}, \quad y_i \cdot x_j = t^{|s_i|} x_j \cdot y_i \]

where \( y_i := y^{[s_i]} \) and \( x_j := x^{[p_j]} \).

We define the surjective algebra homomorphism \( \pi : \text{QT}^\square \to \text{QT}^\vee \) by

\[ x_i \otimes 1 \mapsto x_i, \quad 1 \otimes y_i \mapsto x^{[s_i]}. \]

The kernel of \( \pi \) is generated by \( \{(x^{[s_i]} \otimes 1) - (1 \otimes y_i) \mid i \in I\} \).

Let \( \text{QT}_0, \text{QT}_0^\vee \) and \( \text{QT}_0^\square \) denote the \( \mathbb{C}[t^\pm] \)-subalgebra generated by \( y^v \)'s and \( x^w \)'s. We put

\[ \text{QT}_{sc, \pm} := \text{QT}_0/(t^\pm 1)\text{QT}_0 \]

and define \( \text{QT}_{sc, \pm}^\vee \) and \( \text{QT}_{sc, \pm}^\square \) in the same way. Let \( \{ -, - \} \) denote the Poisson bracket on these quotients.
6.2.2 Integration map

**Theorem 6.4 ([Joy07, Theorem 6.12], [Brih, Theorem 6.3]).** There is a unique $L$-graded linear map

$$I_{\pm}: MH_{sc}(\mathcal{A}) \to QT_{sc, \pm}$$

such that if $X$ is a variety with a map $f: X \to \mathcal{M}_A$ factoring through $\mathcal{M}_A(v) \subset \mathcal{M}_A$ then

$$I_+([f: X \to \mathcal{M}_A]) := e(X) \cdot y^v,$$

$$I_-([f: X \to \mathcal{M}_A]) := \left( \sum_{n \in \mathbb{Z}} n \cdot e((f^*v_{\mathcal{M}_A})^{-1}(n)) \right) \cdot y^v$$

Moreover, $I_{\pm}$ is a Poisson algebra homomorphism.

**Conjecture 6.5 ([KS]).** There exists an $L$-graded $\Lambda$-algebra homomorphism

$$I_{KS}: MH(\mathcal{A}) \to QT(\mathcal{A})$$

defined by taking “motivic invariants”.

**Remark 6.6.** Since it is $L$-graded, the homomorphism $I$ (and $I_{KS}$ if it exists) extends to the completion. We use the same symbol for the extended homomorphism.

6.3 Absence of poles

Let $\mathcal{C}$ be one of the categories $\mathcal{A}$, $\mathcal{A}_k$, $\mathcal{T}_k$, $\mathcal{T}_k[-1]$, $\mathcal{T}_k^+$ and $\mathcal{S}(r)$. As we showed in §4.2, we have a Bridgeland’s stability condition $(Z, \mathcal{P})$ on $D^{b,d}(\mathcal{T})$ such that

$$\mathcal{P}((0, 1]) = \mathcal{A}, \quad \mathcal{P}((0, \phi]) = \mathcal{C}$$

for some $0 < \phi \leq 1$. By the results in [Joy06], we get the algebraic moduli stacks $\mathcal{M}_C$ of objects in $\mathcal{C}$.

We put

$$\varepsilon_C := \log(1 + \mathcal{M}_C) := \sum_{l \geq 1} \frac{(-1)^l}{l} \mathcal{M}_C \cdots \mathcal{M}_C \in \hat{MH}(\mathcal{C})$$

and $\bar{\varepsilon}_C := (L - 1)\varepsilon_C \in \hat{MH}(\mathcal{C})$. Then we have

$$\mathcal{M}_C = \exp(\varepsilon_C) := \sum_{l \geq 1} \frac{1}{l!} \varepsilon_C \cdots \varepsilon_C.$$ (6.3)

**Theorem 6.7 ([Joy08, Section 6.2]).** $\bar{\varepsilon}_{C_k} \in \hat{MH}_0(\mathcal{C})$.

We put

$$\bar{\varepsilon}_C := \bar{\varepsilon}_C|_{L-1} \in \hat{MH}_{sc}.$$

7 Proof

7.1 Hall algebra identities

Throughout this subsection, let \( C \) be one of the categories \( \mathcal{A}, \mathcal{A}_k, \mathcal{T}_k, \mathcal{T}_k[-1], \mathcal{T}_k^\perp \) and \( S_{(r)} \). Let \( \mathcal{M}_C \) be the moduli stack of objects in \( C \).

For an element \( P \in \text{per}_\Gamma \) we define the following moduli stacks:

\[
\text{Hom}(P,C) := \{(f,E) \mid E \in C, f \in \text{Hom}(P,E)\}.
\]

**Proposition 7.1** ([Bria, Lemma 4.3]).

\[ \text{Hilb}_{J}^{1}(i) = \text{Hom}(P_{i},A) \ast M_{A}^{-1} \] (motivic Hilbert scheme identity).

**Proposition 7.2** ([Bria, Lemma 4.1]).

\[ M_{A} = M_{T_{k}} \ast M_{T_{k}^\perp}, \quad M_{A_{k}} = M_{T_{k}^\perp} \ast M_{T_{k}[-1]} \] (motivic torsion pair identity).

For an element \( R \in \mathcal{A} \), let \( \text{Grass}(R,\mathcal{A}) \) be the moduli stack of elements in \( \mathcal{A} \) equipped with surjections from \( R \):

\[ \text{Grass}(R,\mathcal{A}) := \{(f,E) \mid E \in \mathcal{A}, f \in \text{Hom}(R,E), f : \text{surjective}\}. \]

**Proposition 7.3.**

\[ \text{Hom}(R,\mathcal{A}) = \text{Grass}(R,\mathcal{A}) \ast M_{A}^{-1}. \] (7.1)

**Proof.** We can prove in the same way as the motivic Hilbert scheme identities. \( \square \)

**Proposition 7.4.**

\[ \text{Hom}(P_{k,i}[1],\mathcal{T}_{k}) \ast M_{T_{k}^\perp} = \text{Hom}(P_{k,i}[1],\mathcal{A}). \] (7.2)

**Proof.** As in [Bria, §4], a \( \mathbb{C} \)-valued point of \( \text{Hom}(P_{k,i}[1],\mathcal{T}_{k}) \ast M_{T_{k}^\perp} \) is represented by a diagram

\[
P_{k,i}[1] \xrightarrow{0} Y \xrightarrow{X} X \xrightarrow{Z} 0
\]

with \( F \in \mathcal{T}_k \) and \( Z \in \mathcal{T}_k^\perp \). By composing the morphisms in the diagram, we get a family of morphism \( P_{k,i}[1] \to X \) on \( \text{Hom}(P_{k,i}[1],\mathcal{T}_{k}) \ast M_{T_{k}^\perp} \), which induces a morphism from \( \text{Hom}(P_{k,i}[1],\mathcal{T}_{k}) \ast M_{T_{k}^\perp} \) to the moduli stack \( \text{Hom}(P_{k,i}[1],\mathcal{A}) \).

Since \( \text{Hom}(P_{k,i}[1],Z) = \text{Hom}(P_{k,i}[1],Z[-1]) = 0 \), we have

\[
\text{Hom}(P_{k,i}[1],X) = \text{Hom}(P_{k,i}[1],Y).
\]

The axiom of the torsion pair and the equation above provide an equivalence of \( \mathbb{C} \)-valued points induced by the morphism from \( \text{Hom}(P_{k,i}[1],\mathcal{T}_{k}) \ast M_{T_{k}^\perp} \) to \( \text{Hom}(P_{k,i}[1],\mathcal{A}) \).

The following lemma is clear:
Lemma 7.5. 
\[ \mathfrak{H}(P_{k,i}[1], A) = \mathfrak{H}(R_{k,i}, A). \] (7.3)

The following equation plays a principal role in this paper:

Proposition 7.6. We have  
\[ \mathfrak{H}(P_{k,i}[1], T_k) * M_{T_k}^{-1} = \text{Grass}(R_{k,i}, A) \]  
(7.4) 
(motivic quiver Grassmannian identity). In particular, \( \mathfrak{H}(P_{k,i}[1], T_k) * M_{T_k}^{-1} \in \text{MH}_0 \).

Proof.  
\[ \begin{align*}  
\mathfrak{H}(P_{k,i}[1], T_k) * M_{T_k}^{-1} &= \mathfrak{H}(P_{k,i}[1], T_k) * M_{T_k} * M_{T_k}^{-1} * M_{T_k}^{-1} \\
&= \mathfrak{H}(P_{k,i}[1], A) * M_{A}^{-1} \\
&= \mathfrak{H}(R_{k,i}, A) * M_{A}^{-1} \\
&= \text{Grass}(R_{k,i}, A[-1]). 
\end{align*} \]

Proposition 7.7. We have  
\[ \mathcal{M}_{T_k} = (\mathcal{M}_{S(1)})^{\varepsilon(1)} * \cdots * (\mathcal{M}_{S(l)})^{\varepsilon(l)} \]  
(motivic factorization identity).

Proof. We can prove in the same way as the torsion pair identities.

For \( w \in M \), we define  
\[ \mathcal{M}_C[w] := \sum_v L^{(w,v)} \cdot \mathcal{M}_C(v). \]

We put \( w_{k,i} := [\Gamma_{k,i}] \).

Proposition 7.8.  
\[ \mathfrak{H}(P_{k,i}, C) = \mathcal{M}_C[w_{k,i}] \]

Proof. We can realize \( \mathcal{M}_C(v) \) as a quotient stack \([X/GL(v)]\), where \( GL(v) \) is a direct product of \( GL(v_i) \)'s. Note that \( \mathfrak{H}(\Gamma_i, C)(v) \) is a vector bundle of rank \( v_i \) on \( \mathcal{M}_C(v) \), whose pull-back on \( X \) is trivial. Since \( GL(v) \) is special, \( \mathfrak{H}(\Gamma_i, C)(v) \) is Zariski locally trivial.

Corollary 7.9.  
\[ \mathfrak{H}(P_{k,i}[1], T_k) = (\mathfrak{H}(P_{k,i}[1], S(1)))^{\varepsilon(1)} * \cdots * (\mathfrak{H}(P_{k,i}[1], S(l)))^{\varepsilon(l)}. \]
7.2 Idea

The purpose of this subsection is to show the idea of the proof. In this subsection we assume Conjecture 6.5 is true, since it would make the argument clearer. The actual proof starts from the next subsection, which is independent from Conjecture 6.5.

We define the torus automorphism

\[ \hat{q} - \text{Ad}_A := \text{Ad}_{I_{KS}(M_A)} : \tilde{\mathcal{Q}}^T(A) \sim \rightarrow I_{KS}(M_A) \times \bullet \times I_{KS}(M_A)^{-1}. \]

"Proposition" 7.10. (1) We have

\[ \hat{q} - \text{Ad}_A(x_i) = x_i \cdot I_{KS} \left( \text{Hom}(P_i, A) \ast M_A^{-1} \right). \]

(2) We have

\[ \hat{q} - \text{Ad}_A(x_i) = x_i \cdot I_{KS} (\text{Hilb}_J(i)). \]

In particular, the non-commutative Donaldson-Thomas invariants for \( J \) are encoded in the torus automorphism \( \hat{q} - \text{Ad}_A \).

Proof. Note that we have

\[ E \cdot x_i = x_i \cdot E \big|_{y_j = t^{2^k} \delta_{ij}} \quad (7.5) \]

for \( E \in \tilde{\mathcal{Q}}^T(A) \), where \( E \big|_{y_j = t^{2^k} \delta_{ij}} \) is given by substituting \( y_j \cdot t^{2^k} \) for \( y_j \). We call this as the commutator identity. The first claim is a consequence of the commutator identity. The second one follows from the "motivic Hilbert scheme identity" (Proposition 7.1).

We define the torus automorphism

\[ \hat{q} - \text{Ad}_C := \text{Ad}_{I_{KS}(M_C)} : \tilde{\mathcal{Q}}^T(C) \sim \rightarrow \tilde{\mathcal{Q}}^T(C) \]

in the same way.

"Proposition" 7.11. We have the factorization identities

\[ \hat{q} - \text{Ad}_A = \hat{q} - \text{Ad}_{\tau_k} \circ \hat{q} - \text{Ad}_{\tau_k^{-1}}, \quad (7.6) \]

\[ \hat{q} - \text{Ad}_{A_k} = \hat{q} - \text{Ad}_{\tau_k} \circ \hat{q} - \text{Ad}_{\tau_k[-1]}, \quad (7.7) \]

In particular, \( \hat{q} - \text{Ad}_{\tau_k} \) and \( \hat{q} - \text{Ad}_{\tau_k[-1]} \) provide a transformation formula of non-commutative Donaldson-Thomas invariants between \( J \) and \( J_k \).

Proof. They are consequences of the "motivic torsion pair identity" (Proposition 7.2).

"Proposition" 7.12. (1) We have

\[ \hat{q} - \text{Ad}_{\tau_k[-1]}(x_{k,i}) = x_{k,i} \cdot I_{KS} \left( \text{Hom}(P_{k,i}, \tau_k[-1]) \ast M_{\tau_k[-1]}^{-1} \right). \]
(2) The torus automorphism can be described in terms of quiver Grassmannians:

\[ \hat{q} \text{-} \text{Ad}_{\mathcal{T}_k[-1]}(x_{k,i}) = x_{k,i} \cdot I_{KS}\left(\text{Grass}(R_{k,i}[-1], A[-1])\right). \]

In particular, the transformation formula of the non-commutative Donaldson-Thomas invariants can be described in terms of quiver Grassmannians.

Proof. The first claim follows by the commutator identity. The second one follows by the “motivic quiver Grassmannian identity” (Proposition 7.4). \[\square\]

“Proposition” 7.13. We have the factorization identity

\[ \hat{q} \text{-} \text{Ad}_{\mathcal{T}_k[-1]} = \left( \hat{q} \text{-} \text{Ad}_{S(1)[-1]} \right)^{\varepsilon(1)} \circ \cdots \circ \left( \hat{q} \text{-} \text{Ad}_{S(l)[-1]} \right)^{\varepsilon(l)}. \]

Proof. This is a consequences of the “motivic factorization identity” (Proposition 7.7). \[\square\]

7.3 Proof

7.3.1 Definition of the automorphism

Let \( C \) be one of the categories \( \mathcal{A}, \mathcal{A}_k, \mathcal{T}_k, \mathcal{T}_k[-1], \mathcal{T}_k^\perp \) and \( S(r) \). Recall that we have \( \hat{\varepsilon}_C \in \hat{\mathcal{M}}_0(\mathcal{C}) \).

Definition 7.14.

\[ \hat{\text{Ad}}_{C,\sigma} := \exp \left( \text{ad}_{I_{\sigma}(\hat{\varepsilon}_C)} \right) : \hat{Q}_{\text{sc},\sigma}(\mathcal{C}) \sim \xrightarrow{\sim} \hat{Q}_{\text{sc},\sigma}(\mathcal{C}) \]

We will prove Theorem 7.20, 7.21, 7.26 and 7.27 which induce all the results in §5.

7.3.2 Infinitesimal commutator identity

For \( \varepsilon = \sum \varepsilon(v) \in \hat{\mathcal{M}}_0(\mathcal{A}) \) and \( \hat{\varepsilon} = \sum \hat{\varepsilon}(v) \in \hat{\mathcal{M}}_0(\mathcal{A}) \) we define \( \varepsilon[w_i] \in \hat{\mathcal{M}}_0(\mathcal{A}) \) and \( \hat{\varepsilon}\{w_i\} \in \hat{\mathcal{M}}_0(\mathcal{A}) \) by

\[ \varepsilon[w_i] := \sum \chi((w_i), v) \cdot \varepsilon(v), \quad \hat{\varepsilon}\{w_i\} := \sum \chi(w_i, v) \cdot \hat{\varepsilon}(v) \]

respectively. Then we have the following:

Lemma 7.15. We have \( \varepsilon_\mathcal{A}[w_i] - \varepsilon_\mathcal{A} \in \hat{\mathcal{M}}_0(\mathcal{A}) \) and

\[ (\varepsilon_\mathcal{A}[w_i] - \varepsilon_\mathcal{A})|_{t=1} = \hat{\varepsilon}_\mathcal{A}\{w_i\}. \]

(See [6.3] for the definitions.)

We put

\[ \varepsilon^{(p)}_{\varepsilon,\mathcal{A}} := \sum_{j} \frac{(-1)^{j}p!}{j!(p-j)!} \varepsilon_\mathcal{A}[w_i]^{*}(p-j) \ast \varepsilon_\mathcal{A}^{*}(j) \in \hat{\mathcal{M}}_0(\mathcal{A}). \]

Lemma 7.16. \( \varepsilon^{(p)}_{\varepsilon,\mathcal{A}} \in \hat{\mathcal{M}}_0(\mathcal{A}). \)
Proof. Since we have
\[ E^{(p+1)}_{i,A} := (\varepsilon_{A[i]} - \varepsilon_{A}) \cdot E^{(p)}_{i,A} + \frac{1}{L-1} \left[ \varepsilon_{A}, E^{(p)}_{i,A} \right], \]
the claim follows by induction. \qed

Corollary 7.17.
\[ E^{(p+1)}_{i,A}|_{L=1} = \varepsilon_{A[i]} \cdot E^{(p)}_{i,A}|_{L=1} + \left\{ \varepsilon_{A}, E^{(p)}_{i,A}|_{L=1} \right\}. \quad (7.8) \]

Proposition 7.18.
\[ \tilde{\text{Ad}}_{A,\sigma}(x_{i,\sigma}) = x_{i,\sigma} \cdot I_{\sigma}(\varepsilon_{A[w_{i}]} \cdot \varepsilon_{A[w_{i}]}|_{L=1}), \]
\[ \tilde{\text{Ad}}_{A,\sigma}(y_{i,\sigma}) = y_{i,\sigma} \cdot \prod_j I_{\sigma}(\varepsilon_{A[w_{j}]} \cdot \varepsilon_{A[w_{j}]}|_{L=1})^{Q(j,i)}. \]

Proof. We define \( E^{(p)}_{i,A} \in \tilde{\mathcal{Q}} T_{x_{i,\sigma}}(A) \) by
\[ \{ I_{\sigma}(\varepsilon_{A}), - \}^P(x_{i,\sigma}) = E^{(p)}_{i,A} \cdot x_{i,\sigma}. \]
By \( \{6,3\} \), it is suffice to show that \( E^{(p)}_{i,A} = I_{\sigma}(\varepsilon_{A[w_{i}]} \cdot \varepsilon_{A[w_{i}]}|_{L=1}) \). Since we have
\[ \left\{ I_{\sigma}(\varepsilon_{A}), I_{\sigma}(\varepsilon_{A}|_{L=1}) \cdot x_{i,\sigma} \right\} \]
\[ = \left( I_{\sigma}(\varepsilon_{A[w_{i}]}) \cdot I_{\sigma}(\varepsilon_{A[w_{i}]}|_{L=1}) + \left\{ I_{\sigma}(\varepsilon_{A}), I_{\sigma}(\varepsilon_{A[w_{i}]}|_{L=1}) \right\} \right) \cdot x_{i,\sigma} \]
\[ = I_{\sigma}(\varepsilon_{A[w_{i}]}) \cdot E^{(p)}_{i,A}|_{L=1} + \left\{ \varepsilon_{A}, E^{(p)}_{i,A}|_{L=1} \right\} \cdot x_{i,\sigma} \]
\[ = I_{\sigma}(E^{(p)}_{i,A}|_{L=1}) \cdot x_{i,\sigma}, \]
the first equation follows by induction. The second one follows since we have
\[ \varepsilon_{A[w + w']} \cdot \varepsilon_{A[w]}^{-1} = (\varepsilon_{A[w]} \cdot \varepsilon_{A[w]}^{-1})[w'] \cdot (\varepsilon_{A[w']} \cdot \varepsilon_{A[w']}^{-1}). \]
\qed

Similarly we have the following:

Proposition 7.19. Let \( C \) be one of \( A_k, T_k \) and \( S(r) \). Then we have
\[ \tilde{\text{Ad}}_{C,\sigma}(x_{k,i,\sigma}) = x_{k,i,\sigma} \cdot I_{\sigma}(\varepsilon_{C[w_{k,i}] \cdot \varepsilon_{C[w_{k,i}]}}|_{L=1}), \]
\[ \tilde{\text{Ad}}_{C,\sigma}(y_{k,i,\sigma}) = y_{k,i,\sigma} \cdot \prod_j I_{\sigma}(\varepsilon_{C[w_{k,j}] \cdot \varepsilon_{C[w_{k,j}]}}|_{L=1})^{Q(k,j)}. \]

30
7.3.3 Hilbert/Grassmann in the automorphisms

Theorem 7.20.

\[
\hat{\text{Ad}}_{A,\sigma}(x_{i,\sigma}) = x_{i,\sigma} \cdot \left( \sum_{v} e_{\sigma}(\text{Hilb}_1(i, v)) \cdot y_{v,\sigma} \right),
\]
\[
\hat{\text{Ad}}_{A,\sigma}(y_{i,\sigma}) = y_{i,\sigma} \cdot \prod_{j} \left( \sum_{v} e_{\sigma}(\text{Hilb}_1(j, v)) \cdot y_{v,\sigma} \right)^{Q(j,i)}.
\]

**Proof.** This is a consequence of the motivic Hilbert scheme identity (Proposition 7.1) and Proposition 7.18. \(\square\)

Theorem 7.21.

\[
\hat{\text{Ad}}_{\mathbb{T}[-1],\sigma}(x_{k,i,\sigma}) = x_{k,i,\sigma} \cdot \left( \sum_{v} e_{\sigma}(\text{Grass}(k, i, v)) \cdot y_{v,\sigma}^{-1} \right),
\]
\[
\hat{\text{Ad}}_{\mathbb{T}[-1],\sigma}(y_{k,i,\sigma}) = y_{k,i,\sigma} \cdot \prod_{j} \left( \sum_{v} e_{\sigma}(\text{Grass}(k, j, v)) \cdot y_{v,\sigma}^{-1} \right)^{Q(j,i)}.
\]

**Proof.** This is a consequence of the motivic quiver Grassmannian identity (Proposition 7.6) and Proposition 7.19. \(\square\)

Corollary 7.22. The automorphism \(\hat{\text{Ad}}_{\mathbb{T}[-1],\sigma}\) preserves \(Q_{\mathbb{T}_{sc},\sigma}\) and induces an automorphism of \(Q_{\mathbb{T}_{sc},\sigma}\).

**Proof.** The first half is clear from Theorem 7.21 and the second half follows since ad preserves the kernel of the map given in 7.21. \(\square\)

Definition 7.23. Let \(\hat{\text{Ad}}_{\mathbb{T}[-1],\sigma}\) denote the automorphism on \(Q_{\mathbb{T}_{sc},\sigma}\) induced by \(\hat{\text{Ad}}_{\mathbb{C}^k,\sigma}\).

Example 7.24. We put

\[
x_{(r),i,\sigma} := x_{[\Gamma^{R}(r),i]}^{\sigma}, \quad y_{(r),i,\sigma} := y_{[\sigma^{R}(r),i]}^{\sigma}.
\]

Then we have

\[
\text{Ad}_{S(k),\sigma}(x_{(r),i,\sigma}) = \begin{cases} 
  x_{(r),i,\sigma} & i \neq k, \\
  x_{(r),k,\sigma}(1 + (y_{(r-1),k,\sigma})^{-1}) & i = k.
\end{cases}
\]

This gives the cluster transformation for the quiver \(Q_{(r-1)}\) (see Example 5.9).

7.3.4 Factorization identity

Lemma 7.25. For \(X \in \overline{\text{MH}}_{0}(\mathbb{C})\) we have

\[
\hat{\text{Ad}}_{\mathbb{C},\sigma}(I_{\sigma}(X|_{L=1})) = I_{\sigma}\left((\mathcal{M}_{\mathbb{C}} \ast X \ast \mathcal{M}_{\mathbb{C}}^{-1})|_{L=1}\right)
\]
Proof. Note that we have
\[
\mathcal{M}_{C} * X * \mathcal{M}_{C}^{-1}|_{L=1} = \left(\exp([\varepsilon_{C}, -])(X)\right)|_{L=1} = \left(\exp\left(\frac{1}{L-1}([\varepsilon_{C}, -])(X)\right)\right)|_{L=1} = \exp(\{\varepsilon_{C}, -\})(X)|_{L=1}.
\]
Then the claim follows since \(I_{\sigma}\) respects the Poisson bracket. □

Theorem 7.26.
\[
\hat{\text{Ad}}_{d, \sigma} = \hat{\text{Ad}}_{\mathcal{T}_{K}, \sigma} \circ \hat{\text{Ad}}_{\mathcal{T}_{K}^{-1}, \sigma}, \quad \hat{\text{Ad}}_{A_{K}, \sigma} = \hat{\text{Ad}}_{\mathcal{T}_{K}^{-1}, \sigma} \circ \hat{\text{Ad}}_{\mathcal{T}_{K}[-1], \sigma}.
\]

Theorem 7.27.
\[
\text{Ad}_{\mathcal{T}_{K}[-1], \sigma} = \left(\text{Ad}_{S(1)[-1], \sigma}\right)^{\varepsilon(1)} \circ \cdots \circ \left(\text{Ad}_{S(l)[-1], \sigma}\right)^{\varepsilon(l)}.
\]

We will show the proof of
\[
\text{Ad}_{\mathcal{T}_{K}, \sigma} = \left(\text{Ad}_{S(1), \sigma}\right)^{\varepsilon(1)} \circ \cdots \circ \left(\text{Ad}_{S(l), \sigma}\right)^{\varepsilon(l)} \quad (7.9)
\]
which is equivalent to Theorem 7.27 (we can prove Theorem 7.26 in the same way). We put \(\delta(r) := \mathcal{M}_{C}(r)\). First, we can see the following identity by induction with respect to \(r\) using Proposition 7.18 and Lemma 7.25:
\[
\left(\hat{\text{Ad}}_{C(r), \sigma}\right)^{\varepsilon(r)} \circ \cdots \circ \left(\hat{\text{Ad}}_{C(l), \sigma}\right)^{\varepsilon(l)} \left(x_{\sigma}^{w}\right) = \prod_{r'=r}^{l} I_{\sigma} \left(\delta^{\varepsilon(r)} * \cdots * \delta^{\varepsilon(r'-1)} * (\delta_{(r')}[w])^{\varepsilon(r')} * \delta_{-\varepsilon(r')} * \cdots * \delta_{-\varepsilon(l)}\right)|_{L=1}
\]
Then we have
\[
\left(\hat{\text{Ad}}_{C(1), \sigma}\right)^{\varepsilon(1)} \circ \cdots \circ \left(\hat{\text{Ad}}_{C(l), \sigma}\right)^{\varepsilon(l)} \left(x_{\sigma}^{w}\right) = x_{\sigma}^{w} \prod_{r'=1}^{l} I_{\sigma} \left(\delta^{\varepsilon(r)} * \cdots * \delta^{\varepsilon(r'-1)} * (\delta_{(r')}[w])^{\varepsilon(r')} * \delta_{-\varepsilon(r')} * \cdots * \delta_{-\varepsilon(l)}\right)|_{L=1} = x_{\sigma}^{w} \cdot I_{\sigma} \left(\mathcal{M}_{\mathcal{T}_{K}}[w_{k, l}] * \mathcal{M}_{\mathcal{T}_{K}}^{-1}|_{L=1}\right) = \text{Ad}_{\mathcal{T}_{K}, \sigma}(x_{\sigma}^{w}).
\]
Here we use Proposition 7.17 and Corollary 7.20 for the second equation and Proposition 7.18 for the last one.

8 Applications for cluster algebras

8.1 Quiver with the principal framing

Let \(Q^p\) be the following quiver:
This is called the quiver with the principal framing associated to $Q$.

A potential $W$ of $Q$ can be taken as a potential of $Q^{\text{pf}}$. In the rest of this paper, we assume that $(Q^{\text{pf}}, W)$ is successively $f$-mutable with respect to a sequence $k$. We apply Theorem 3.4 for $(Q^{\text{pf}}, W)$ and $k$ to get the sequence $\epsilon'(1), \ldots, \epsilon'(l)$. We put

$$\Phi^k_{\text{pf}} := \Phi^k_{\epsilon'(l)} \circ \cdots \circ \Phi^k_{\epsilon'(1)} : D_k \to \mathcal{D}_k^{\text{pf}}.$$  

Let $\phi^k_{\text{pf}}$ denote the homomorphism induced on the lattices $L_{Q^{\text{pf}}}$ or $M_{Q^{\text{pf}}}$. Let $\epsilon(1), \ldots, \epsilon(l)$ be the sequence associated to the $\text{QP} (Q, W)$ and the sequence $k$.

**Proposition 8.1.**

1. $\epsilon(r) = \epsilon'(r)$ for any $r$.  
2. $\phi^k_{\text{pf}}([s_{i^*}]) = [s_{k_i}^+]$ for any $i^* \in I^*$.  
3. $\phi^k_{\text{pf}}(L_Q) \subset L_{Q^k}$ and $\phi^k_{\text{pf}}|_{L_Q} : L_Q \to L_Q$ coincides with $\phi_k$.  
4. $\phi^k_{\text{pf}}(M_Q) \subset M_{Q^k}$ and $\phi^k_{\text{pf}}|_{M_Q} : M_Q \to M_Q$ coincides with $\phi_k$.

**Proof.** We prove all the claims together by induction with respect to the length of the sequence $k$.

Assume the claim holds for the sequence $k^- = (k_1, \ldots, k_{l-1})$. Note that $\epsilon(l)$ (resp. $\epsilon'(l)$) is determined by the condition

$$\epsilon(l) \times (\phi_{k^-})^{-1}([s_{k_i^-}^\times]) \in C_A \subset L_Q \quad (\text{resp. } \epsilon'(l) \times (\phi_{k^-}')^{-1}([s_{k_i^-}^\times]) \in C_{A^\text{pf}} \subset L_{Q^k}).$$

By the induction assumption (3), we get $\epsilon(l) = \epsilon'(l)$.

We assume $\epsilon(l+1) = +$ (for the case of $\epsilon(l+1) = -$, we can see in the same way). Then we have

$$Q_{k'}(k_{l+1}, i^*) = \chi([s_{k'}^\times, k_{l+1}^+], [s_{k_i}^\times]) = \chi((\phi_{k^-})^{-1}([s_{k_i^-}^\times]), (\phi_{k'}^{-1})([s_{k_i^-}^\times])) = \chi((\phi_{k^-})^{-1}([s_{k_i^-}^\times], [s_{i^*}^\times])) \geq 0$$

for any $i^*$. Then the claims follow [2.2] and [2.3].

**Remark 8.2.** For a sequence $k$ and a vertex $i \in I$, the vector $(Q_k(i, j^*))_{j^* \in I^*}$ is so called the $c$-vector. Now we see that the $c$-vector is given by $(\phi_{k'})^{-1}([s_{k_i}^\times])$.

We have the following triangulated categories:

$$\mathcal{D}_{Q^{\text{pf}}} = D_{Q^{\text{pf}}},$$
$$\mathcal{D}^\text{pf} := D^\text{id}_{Q^{\text{pf}}},$$
$$\bar{\mathcal{D}}' : \text{the full subcategory of } \mathcal{D}^\text{pf} \text{ consisting of objects whose cohomologies are supported on } I,$$
$$\mathcal{D}' := \mathcal{D}^\text{pf} \cap \bar{\mathcal{D}}'.$
The canonical t-structure of $\mathcal{D}^{\text{pf}}$ induces t-structures of $\mathcal{D}^{\text{pf}}, \mathcal{D}'$ and $\mathcal{D}'$. Let $\mathcal{A}^{\text{pf}}, \tilde{\mathcal{A}}_{\text{pf}}, \mathcal{A}'$ and $\tilde{\mathcal{A}}'$ denote the cores of t-structures.

**Lemma 8.3.**

1. $\Phi^{\text{pf}}_{k}(s_{i*}) = s_{k,i*}$ for any $i^* \in I^*$.
2. $\tilde{T}_{k}^{\text{pf}} \subset \mathcal{A}'$.

**Proof.** The first claim follows Lemma 8.1 (2). For (2), let $\tilde{T}_{k}^{\text{pf}}$ denote the cores of t-structures.

We put

$$\mathcal{A}^{\text{pf}}_{k} := (\Phi^{\text{pf}}_{k})^{-1}(\text{Mod}_k(\mathcal{Q}^{\text{pf}}, \mathcal{W}_k))$$

and

$$\tilde{\mathcal{A}}'_{k} := \mathcal{A}^{\text{pf}}_{k} \cap \mathcal{D}', \quad \tilde{\mathcal{A}}''_{k} := \mathcal{A}^{\text{pf}}_{k} \cap \mathcal{D}''.

Then $\tilde{\mathcal{A}}_{k}$ (resp. $\tilde{\mathcal{A}}'_{k}$) coincides with the full subcategory of $\mathcal{A}_{k}^{\text{pf}}$ consisting of objects supported on $I$ (with finite dimensional cohomologies).

We set $\tilde{T}'_{k} := \tilde{T}_{k}^{\text{pf}}$ (resp. $\tilde{T}''_{k} := \tilde{T}_{k}^{\text{pf}}$) and

$$\tilde{F}'_{k} := \tilde{F}_{k}^{\text{pf}} \cap \mathcal{A}', \quad (\text{resp. } \tilde{F}''_{k} := \tilde{F}_{k}^{\text{pf}} \cap \mathcal{A}'').

Then, $(\tilde{T}'_{k}, \tilde{F}'_{k})$ (resp. $(\tilde{T}''_{k}, \tilde{F}''_{k})$) gives a torsion pair of $\tilde{A}'$ (resp. $\tilde{A}'$) and the tilted t-structure coincides with $\tilde{A}_{k}$ (resp. $\tilde{A}_{k}^{\text{pf}}$).

**8.2 CC formula for $(Q, W)$ and $(Q^{\text{pf}}, W)$**

We put

$$R^{\text{pf}}_{k,i} := H^{1}_{\text{dR}}((\Phi^{\text{pf}}_{k})^{-1}(P^{\text{pf}}_{k,i}))$$

and

$$\text{Grass}^{\text{pf}}(k; i, v) := \{ R^{\text{pf}}_{k,i} \to V \mid V \in \mathcal{A}', [V] = v \}.

We apply Theorem 8.3 for $(Q^{\text{pf}}, W)$ we get

$$FZ^{\text{pf}}_{k,i}(\mathcal{X}) = X_{k,i} \cdot \left( \sum_{v} e \left( \text{Grass}^{\text{pf}}(k; i, v) \right) \cdot Y^{-v} \right)

where $Y_{j} = X_{j}^{-1} \cdot \prod_i (X_{i})^{Q(i, j)}$. Then we have

$$F_{k,i}(y) := FZ^{\text{pf}}_{k,i}(\mathcal{X})_{|X_{i}=1, i, \ast = y_{i}} = \sum_{v} e \left( \text{Grass}^{\text{pf}}(k; i, v) \right) \cdot y^{v}.

(8.1)

On the other hand, we put

$$R^{\text{pf}}'_{k,i} := H^{1}_{\text{dR}}((\Phi^{\text{pf}}_{k})^{-1}(P_{k,i}))$$

and

$$\text{Grass}'(k; i, v) := \{ R^{\text{pf}}'_{k,i} \to V \mid V \in \mathcal{A}', [V] = v \}.

We will apply the same arguments as in 7 for $\mathcal{D}^{\Gamma}$. Let $\text{Hom}_{\mathcal{D}^{\Gamma}}(P_{k,i}, T_{k})$ be the moduli stack which parametrizes homomorphisms in $\mathcal{D}^{\Gamma}$ from $P_{k,i}$ to elements in $\mathcal{T}^{\text{pf}}_{k}$. We can verify all the lemmas and propositions in 7.2 and 7.3.
if we replace Grass\((k; i, \nu)\) with Grass'\((k; i, \nu)\). As a consequence, we get the following modification of the Caldero-Chapoton type formula for \((Q, W)\):

\[
F_{Z, k, i}(x) = x_{k, i} \cdot \left( \sum_\nu e(\text{Grass}'(k; i, \nu)) \cdot y^{-\nu} \right). \tag{8.2}
\]

where \((y)^{-\nu} = \prod_j (y_j)^{-e_j}\) and \(y_j = \prod_i (x_i)^{Q(i, j)}\).

**Proposition 8.4.**

\(R_{pf, k, i} = R'_{k, i}\)

**Proof.** Since we have no non-trivial morphism from

\[
\ker \left( P_{pf, k, i} \rightarrow R_{pf, k, i} \right)
\]

to \(R'_{k, i}\), the composition

\[
P_{pf, k, i} \rightarrow P_{k, i} \rightarrow R'_{k, i}
\]

factors through \(P_{pf, k, i} \rightarrow R_{pf, k, i}\):

\[
\begin{array}{ccc}
P_{pf, k, i} & \rightarrow & R_{pf, k, i} \\
\downarrow & & \downarrow \\
P_{k, i} & \rightarrow & R'_{k, i}
\end{array}
\]

On the other hand, since \(R_{pf, k, i}\) is supported on \(I\) the surjection \(P_{pf, k, i} \rightarrow R_{pf, k, i}\) factors through \(P_{k, i}\). By the same reason, this map factors through \(P_{k, i} \rightarrow R'_{k, i}\):

\[
\begin{array}{ccc}
P_{pf, k, i} & \rightarrow & R_{pf, k, i} \\
\downarrow & & \downarrow \\
P_{k, i} & \rightarrow & R'_{k, i}
\end{array}
\]

These two morphisms are the inverse of each other.

**8.3 \(F\)-polynomials and \(g\)-vectors**

Combining \((8.1), (8.2)\) and Proposition 8.4 we get

\[
F_{Z, k, i}(x) = x_{k, i} \cdot F_{k, i}(y^{-1}). \tag{8.3}
\]

Finally, we have the following description of \(F\)-polynomials and \(g\)-vectors:

**Theorem 8.5.**

(1) \(F_{k, i}(y) = \sum_\nu e(\text{Grass}'(k; i, \nu)) \cdot y^\nu\)

(2) \(g_{k, i} = \phi_k^{-1}([\Gamma_{k, i}]) \in M_Q\).
Since $L_J \otimes \mathbb{R}$ and $M_J \otimes \mathbb{R}$ are dual to each other via $\chi$ and $\phi_k$ preserves $\chi$, we get the following description of the $y$-vector.

**Corollary 8.6.**

$$y_{k,i} = \phi_k([s_i]) \in L_{Q_k}.$$  

**Remark 8.7.** The $g$-vector can be viewed as a tropical counterpart of the $x$-variable, while the $c$-vector can be viewed as a tropical counterpart of the $y$-variable. The duality between the $g$- and the $c$-vectors is called toropical duality in [Nakb]. From our view point, the $x$-variable corresponds to the “projective” $\Gamma_i$ and the $y$-variable corresponds to the simple $s_i$, and the toropical duality is a consequence of the duality between $\{\Gamma_i\}$ and $\{s_i\}$.

### 8.3.1 Conjectures on $F$-polynomials

The following claims follow directly from the description in Theorem 8.5.

**Theorem 8.8** ([FZ07, Conjecture 5.4], [DWZ, Theorem 1.7]). Each polynomial $F_{k,i}(y)$ has constant term $1$.

**Theorem 8.9** ([FZ07, Conjecture 5.5], [DWZ, Theorem 1.7]). Each polynomial $F_{k,i}(y)$ has a unique monomial of maximal degree. Furthermore, this monomial has coefficient $1$, and it is divisible by all the other occurring monomials.

### 8.3.2 Conjectures on $g$-vectors

**Theorem 8.10** ([FZ07, Conjecture 7.10(2)], [DWZ, Theorem 1.7]). For any sequence $k$, the vectors $\{g_{k,i}\}_{i \in I}$ form a $\mathbb{Z}$-basis of the lattice $\mathbb{Z}^n$.

**Proof.** This is clear from Theorem 8.5 (2).

**Theorem 8.11** ([FZ07, Conjecture 6.13], [DWZ, Theorem 1.7]). For any sequence $k$ and a vertex $i \in I$, the components of the vector $g_{k,i}$ are either all non-negative, or all non-positive.

**Proof.** In the same way as Theorem 8.4, we can see that $\Phi_k(s_i) \in A_k$ or $\Phi_k(s_i) \in A_k[1]$. Then, the claim is a consequence Corollary 8.6.

**Theorem 8.12** ([FZ07, Conjecture 7.12], [DWZ, Theorem 1.7]). For a sequence $k = (k_0, \ldots, k_l)$, we take a new sequence $k^* := (k_1, \ldots, k_l)$. Then we have

$$g_{k,i} = \begin{cases} -g_{k,i} & i = k_0, \\ g_{k,i} + Q(i,k_0) \cdot g_{k_0,k} & i \neq k_0, \varepsilon(0) = -, \\ g_{k,i} + Q(k_0,i) \cdot g_{k_0,k} & i \neq k_0, \varepsilon(0) = +. \\ \end{cases}$$

**Proof.** This is a consequence of (2.3) and Corollary 8.6.

---

9The duality has proved in [Nakb] for skewsymmetric matrices. For skewsymmetrizable matrices, it is still a conjecture.
8.4 $g$-vectors determine $F$-polynomials

We define 
$$\zeta': \mathbb{R} \to \text{Stab}(D'T).$$

in the same way as §4.1. For $\theta \in \mathbb{R}$, let $\mathcal{A}_\theta$ denote the core of the t-structure corresponding to $\zeta'(\theta)$ and $(T'_\theta, F'_\theta)$ be the corresponding torsion pair. For $\theta \in C_{\mathbb{R}}^*$, we have $\mathcal{A}_{\zeta'(\theta)} = \mathcal{A}_\theta$.

Theorem 8.13 ([FZ07 Conjecture 7.10(1)], [DWZ Theorem 1.7]). Suppose we have
$$\sum_{i \in J} a_i \cdot g_{k,i} = \sum_{i \in J'} a'_i \cdot g_{k,i'}$$
for some nonempty subsets $J, J' \subset I$ and some positive real numbers $a_i$ and $a'_i$.

Then there is a bijection $\kappa: J \to J'$ such that for every $i \in J$ we have
$$a_i = a'_\kappa(i), \quad g_{k,i} = g_{\kappa(i),k'}, \quad F_{k,i} = F_{k,\kappa(i)}.$$ 

In particular, $F_{k,i}$ is determined by $g_{k,i}$.

Proof. By Theorem 8.5, $g_{k,i}$ is primitive and
$$g_{k,i} \in \bigcap_{j \neq i} W_{k,j} \cap C_k^-$$
where
$$W_{k,j} := \{ \theta \in \mathbb{R} \mid \langle \theta, [g_{k,j}] \rangle = 0 \}.$$ 

Then we have
$$\text{Int} \left( \bigcap_{j \in J} W_{k,j} \cap C_k^- \right) = \left\{ \sum_{i \in J} a_i \cdot g_{k,i} \mid a_i > 0 \right\}.$$ 

The bijection $\kappa: J \to J'$ and
$$a_i = a'_\kappa(i), \quad g_{k,i} = g_{\kappa(i),k}$$
follow from this description.

Let $\mathcal{C}_{k,J}$ be the full subcategory of $\mathcal{A}_k$-modules supported on
$$\{ i \mid i \neq J, \varepsilon(k,i) = + \}.$$ 

Then we have
$$\mathcal{A}'_\theta = \mathcal{A}_k^\dagger(C_{k,J}[1], -C_{k,J})$$

We define
$$\text{Ad}_{T'_\theta}^{\text{pf}} \circ \text{Ad}_{\mathcal{C}_{k,J}}^{\text{pf}} : QT_{\text{Sc}}^{\text{pf}} \cong QT_{\text{Sc}}^{\text{pf}}$$
in the same way in §7.3.1 then we have
$$\text{Ad}_{T'_\theta}^{\text{pf}} \circ \text{Ad}_{\mathcal{C}_{k,J}}^{\text{pf}} = \text{Ad}_{\mathcal{A}_\theta}^{\text{pf}}$$
as Theorem 7.27.

Note that $\text{Ad}_{\mathcal{A}_\theta}^{\text{pf}}$ depends on $\theta$, but not on $k$. Hence we get $F_{k,i} = F_{\kappa(i),k'}$. 

10 The category $\mathcal{A}_\theta^{\text{pf}}$ is not a module category in general.
