Abstract—To mitigate the space occupation and aesthetic problems of indoor dense small cell deployment, a microstrip antenna with multiple layer configuration operating at 3.5 GHz is embedded in concrete all for indoor communication. The impact of embedding depth and concrete dielectric constant on antenna gain and input reactance are investigated, and simple empirical formulas are obtained based on full-wave simulation. The results in present work provide a good guidance to antenna designers and architects for concrete embedded antenna deployment and communication-friendly building materials selection.

Keywords—Concrete embedded antenna, empirical formula, performance prediction.

I. INTRODUCTION

Ultra dense small cell deployment is regarded as the most promising way to meet the traffic demand, and deploying small cells densely in buildings is anticipated to improve throughput in the next generation of cellular communication [1]. However, deployment of small cells with a number of antennas or antenna arrays will occupy extra space which leads to negative effects on usage of the buildings. A feasible solution to mitigate these negative effects is to embed antennas into the building materials. Most researches on concrete embedded antennas were focused on data and power transmission of wireless sensors embedded in concrete to monitor structural health [2]. In [3], a concrete floor embedded RFID tag antenna was presented. A feasible embedded antenna requires not only high electromagnetic performance but also robust mechanical behaviour. In [4], a structurally integrated antennas with multilayered structure have been proposed. To the best of our knowledge, no research on concrete embedded antenna for indoor communication has been reported.

In fact, the embedding is challenging since the strong coupling between antenna and concrete can significantly affect antenna performance. Thus, for obtaining the optimal antenna performance, the concrete electrical property should be taken into account in the building design stage. In this paper, a concrete embedded antenna is proposed and its gain and input reactance variations against embedding depth and concrete dielectric constant are investigated by full-wave simulation. Furthermore, simple empirical formulas are fitted based on simulation results to facilitate fast prediction of antenna performance.

II. SYSTEM MODEL

In current work, the structurally integrated antenna proposed in [4] is selected due to its excellent mechanical and electrical performances. As shown in Fig. 1, the antenna is fully embedded in a solid concrete slab with a dimension of 1000 mm × 1000 mm × 200 mm, the embedding depth d is measured as the distance from the front concrete-air interface to the top surface of antenna. The concrete dielectric constant εr varies from 4 to 9, and the loss tangent is fixed to be 0.03 (tan δ = 0.03). The multilayer configuration of the structurally integrated antenna is shown in Fig. 1. The antenna mainly consists of a microstrip patch etched on a Rogers RT5880 substrate and is sandwiched among a lower facesheet (LF), a honeycomb structure and an upper facesheet (UF).

The electrical properties and thickness of each layer are listed in Table I. The patch is optimized to operate at 3.5 GHz, and its dimensions are fixed. All the simulations are performed by Computer Simulation Technology (CST) Studio.

III. RESULTS AND DISCUSSION

TABLE I: Electrical properties and thickness for each layer

| Layer     | Material     | εr | tan δ | Thickness (mm) |
|-----------|--------------|----|-------|----------------|
| UP        | Roger 3003   | 5  | 0.001 | d1 = 0.25      |
| Honeycomb | Air          | 1  | 0     | d2 = 10        |
| Substrate | Roger 5880   | 2.2| 0.0009| d3 = 1         |
| LF        | Roger 3003   | 3  | 0.001 | d4 = 0.25      |

The antenna performance is affected by the embedding depth and the concrete dielectric constant. Thus, for obtaining the optimal antenna performance, the concrete electrical property should be taken into account in the building design stage. In this paper, a concrete embedded antenna is proposed and its gain and input reactance variations against embedding depth and concrete dielectric constant are investigated by full-wave simulation. Furthermore, simple empirical formulas are fitted based on simulation results to facilitate fast prediction of antenna performance.
noted that the increase of $d$ makes $G$ decrease in a fluctuation, while the increasing $\epsilon_r$ leads to the decline of $G$. Thus, the gain $G$ can be formulated as a linear decreasing function superposed with a damping sinusoidal function as (1). The input reactance oscillates damply with the embedding depth, so it can be modeled by a sinusoidal function with attenuated amplitude as (2):

$$G = A_1(\epsilon_r)e^{B_1(\epsilon_r)d}\sin[C_1(\epsilon_r)d] + D_1(\epsilon_r)[d + E_1(\epsilon_r)],$$

(1)

$$X_{in} = A_2(\epsilon_r) + B_2(\epsilon_r)e^{C_2(\epsilon_r)d}\cos(D_2(\epsilon_r)d + E_2(\epsilon_r)),
$$

(2)

where $G$ and $X_{in}$ are measured in dBi and Ohm, respectively, and $d$ is measured in meter.

In formula (1) and (2), $A_i$, $B_i$, $C_i$, $D_i$ and $E_i$ ($i=1, 2$) are undetermined coefficients which are functions of $\epsilon_r$. By nonlinear fitting, formulas of $G$ for some dielectric constants are listed in Table III. After careful inspection of the results in Table III, the coefficients in formula (1) can be formulated as linear function of $\epsilon_r$, and the fitted formulas for the five coefficients in (1) are listed in Table IV. Substituting the results in Table IV into (1), the empirical formula of $G$ as a function of $d$ and $\epsilon_r$ can be written as:

$$G = (0.53\epsilon_r - 0.89)e^{(1.47\epsilon_r-32.75)d}\sin[(22.09\epsilon_r + 250.80)d] + (-1.43\epsilon_r - 9.98][d + (0.05\epsilon_r - 0.54)].$$

(3)

Following the same fitting procedure of $G$, the formulas of $X_{in}$ as a function of $d$ and $\epsilon_r$ can be written as:

$$X_{in} = (0.76\epsilon_r - 6.16) + (0.65\epsilon_r + 10.52)e^{(-0.36\epsilon_r-17.94)d}\cos[(29.35\epsilon_r + 175.50)d + (-0.02\epsilon_r + 8.13)].$$

(4)

Fig. 2: Simulated results.

(a) $G$ against $d$ and $\epsilon_r$
(b) $X_{in}$ against $d$ and $\epsilon_r$

Fig. 3: Fitted results.

(a) $G$ against $d$ and $\epsilon_r$
(b) $X_{in}$ against $d$ and $\epsilon_r$

Table III: Formulas of gain for different $\epsilon_r$

| $\epsilon_r$ | Nonlinear regression formulation |
|------------|---------------------------------|
| 4          | $G = 0.93e^{-20.29d}\sin(342.50d) - 16.03 - (d - 0.37)$ |
| 6          | $G = 2.31e^{-24.50d}\sin(381.40d) - 18.88 - (d - 0.21)$ |
| 8          | $G = 3.31e^{-20.97d}\sin(429.10d) - 20.82 - (d - 0.14)$ |

Table IV: Linear fitting formulas for coefficients in (1)

| Coefficient | Formulation |
|------------|-------------|
| $A_1$      | $A_1 = 0.05\epsilon_r - 0.89$ |
| $A_2$      | $A_2 = 0.10\epsilon_r - 6.16$ |
| $B_1$      | $B_1 = 1.47\epsilon_r - 32.75$ |
| $B_2$      | $B_2 = 0.65\epsilon_r + 10.52$ |
| $C_1$      | $C_1 = 22.09\epsilon_r + 250.80$ |
| $C_2$      | $C_2 = -0.36\epsilon_r - 17.94$ |
| $D_1$      | $D_1 = -1.43\epsilon_r - 9.98$ |
| $D_2$      | $D_2 = -0.02\epsilon_r + 8.13$ |
| $E_1$      | $E_1 = 0.05\epsilon_r - 0.54$ |
| $E_2$      | $E_2 = 0.10\epsilon_r - 6.16$ |

A microstrip antenna is embedded into a concrete wall for indoor communication. How antenna performances are affected by both the embedding depth and the concrete dielectric constant was investigated. It is found that the gain decrease with the increase of embedding depth, and the input reactance displays a damped periodical oscillation with the embedding depth. It is also found that a larger concrete dielectric constant leads to smaller gain. Simple empirical formulas are fitted as two-dimensional regression function of the embedding depth and the dielectric constant for performance prediction, which facilitate the concrete embedded antenna deployment and communication-friendly building materials selection.

ACKNOWLEDGMENT

The research is funded in part by the European Union’s H2020-MSCA-IF-GATE (843133) and in part by the European Union’s H2020-MSCA-IF-AceLSAA (752644). The authors would like to thank the European Union’s H2020-MSCA-IF-AceLSAA (752644) for their financial support.
