Natural History of and Dynamic Changes in Clinical Manifestation, Serology, and Treatment of Brucellosis, China

Hongyu Wang,¹ Hongyan Liu,¹ Qiran Zhang,¹ Xiaobo Lu,¹ Dan Li,¹ Haocheng Zhang,¹ Yan A. Wang, Rongjiong Zheng, Yi Zhang, Zhangfan Fu, Ke Lin, Chao Qiu, Yan O. Wang, Ye Gu, Jingwen Ai, Wenhong Zhang

In support of improving patient care, this activity has been planned and implemented by Medscape, LLC and Emerging Infectious Diseases. Medscape, LLC is jointly accredited by the Accreditation Council for Continuing Medical Education (ACCME), the Accreditation Council for Pharmacy Education (ACPE), and the American Nurses Credentialing Center (ANCC), to provide continuing education for the healthcare team.

Medscape, LLC designates this Journal-based CME activity for a maximum of 1.00 AMA PRA Category 1 Credit(s)™. Physicians should claim only the credit commensurate with the extent of their participation in the activity.

Successful completion of this CME activity, which includes participation in the evaluation component, enables the participant to earn up to 1.0 MOC points in the American Board of Internal Medicine’s (ABIM) Maintenance of Certification (MOC) program. Participants will earn MOC points equivalent to the amount of CME credits claimed for the activity. It is the CME activity provider’s responsibility to submit participant completion information to ACCME for the purpose of granting ABIM MOC credit.

All other clinicians completing this activity will be issued a certificate of participation. To participate in this journal CME activity: (1) review the learning objectives and author disclosures; (2) study the education content; (3) take the post-test with a 75% minimum passing score and complete the evaluation at http://www.medscape.org/journal/eid; and (4) view/print certificate. For CME questions, see page 1542.

Release date: June 21, 2022; Expiration date: June 21, 2023

Learning Objectives

Upon completion of this activity, participants will be able to:

• Describe diagnosis and epidemiologic features of human brucellosis, according to a large, retrospective cohort study in China

• Determine clinical characteristics of human brucellosis during the disease course and after treatment, according to a large, retrospective cohort study in China

• Identify serologic surveillance of human brucellosis during the disease course and after treatment, and long-term treatment outcomes, according to a large, retrospective cohort study in China

CME Editor

Serum agglutination test plus exposure history were used to diagnose most cases of human brucellosis in 2 China provinces. After appropriate treatment, 13.3% of acute brucellosis cases progressed to chronic disease; arthritis was an early predictor. Seropositivity can persist after symptoms disappear, which might cause physicians to subjectively extend therapeutic regimens.

Brucellosis is a zoonosis caused by the bacterium Brucella that typically manifests in insidious onset of fever, malaise, arthralgias, and nonspecific physical findings, including hepatomegaly, splenomegaly, or lymphadenopathy (1). Accurate diagnosis and proper management of human brucellosis continues to challenge clinicians. Several studies have described the clinical characteristics of human brucellosis and evaluated diagnostic methods, but most of these studies are cross-sectional and focused on baseline manifestations or diagnostic accuracy (2–6). Much remains unclear about the dynamic changes of clinical manifestations, serology, and the tendency of brucellosis to persist and become chronic during development and treatment.

The Study

We conducted a retrospective, real-world cohort study at 8 hospitals in Liaoning and Xinjiang Provinces, 2 of the most brucellosis-endemic areas in China, to investigate the characteristics of brucellosis during natural history and treatment. We enrolled patients confirmed to have brucellosis during 2014–2020. We collected information on contact history, clinical manifestations, laboratory parameters, and antibiotic therapy from the hospital information system and treatment outcome by telephone (Appendix, https://wwwnc.cdc.gov/EID/article/28/7/21-1766-App1.pdf). This research was carried out according to the principles of the Declaration of Helsinki. The study protocol was approved by the Ethics Committees of Huashan Hospital of Fudan University (KY2019–412). Informed consent was obtained from all patients before diagnosis, and patient data were anonymized.

We included 5,270 patients confirmed to have brucellosis during September 2014–December 2020. Three persons were excluded for positive HIV detection, 668 were excluded because they lacked positive culture or serologic results, and 1,191 were excluded for incomplete clinical information. We ultimately enrolled 3,411 persons; we performed follow-up for 1,676 persons at periods of 14, 28, 42, 90, 180, 360, or 720 days after diagnosis and treatment initiation (Appendix Figure 1).

Median participant age was 48 years (interquartile range 35.8–57.0 years). Most participants were men (2,452; 73.9%) and worked as farmers or herdsmen (2,776; 82.4%). A total of 2,066 (60.6%) had exposure history with suspicious animals, 1,686 (49.4%) had contact history with brucellosis patients, and 1,129 (33.1%) resided in a brucellosis-endemic area (Table 1).

Blood cultures were collected from 1,827 participants for diagnostic purposes; results were positive in 424 (23.2%) persons. Serum agglutination tests (SAT) were collected from 3,381 persons, and 3,351 (99.1%) reported positive results. A total of 1,797 persons received both tests; 394 (21.9%) tested positive on both, 28 (1.6%) tested positive by culture only, and 1,375 (76.5%) tested positive by SAT only. Among 2,264 patients with positive titers on SAT, titers were >1:400 in 36.0%, 1:200 in 28.4%, 1:100 in 35.2%, and 1:50 in 0.4% (Table 1). Seasonal epidemics were observed during March–July each year, whereas total diagnosed cases decreased annually during 2015–2019 (Appendix Figure 2).

We observed the natural history of brucellosis with symptom duration <180 days (early stage) or ≥180 days (late stage) before patients received antibiotic therapy. The 3 most common symptoms in early-stage disease were fatigue (72.3%), fever (64.0%), and sweating (34.6%). The most common symptoms in late-stage disease were fatigue (71.6%), fever (61.1%), and arthritis (36.6%) (Figure 1, panel A). Arthritis was more common in the late stage than the early stage (20.7%; p<0.0001). We observed neurobrucellosis in 9.9% of patients in the early stage and in 4.1% of patients in the late stage (p = 0.0020). After adjusting for confounding factors through propensity score-matching (PSM) (7), culture-diagnosed patients (compared with patients with SAT-diagnosed brucellosis) had higher incidence of fever (311 [81.8%] vs. 244 [58.9%]; p<0.0001), sweating (177 [46.6%] vs. 95 [25.0%]; p<0.0001), poor appetite (271 [71.3%] vs. 195 [51.3%]; p<0.0001), and hepatosplenomegaly (67 [17.6%] vs. 45 [11.8%]; p<0.0001). These patients also exhibited higher C-reactive protein (34.5 ± 1.8 vs. 24.7 ± 1.7; p = 0.0002) and erythrocyte sedimentation rate (45.6 ± 1.7 vs. 29.3 ± 1.4; p = 0.0290), which could be caused by active bloodstream infection (Appendix Table 1).

Among 1,676 participants with whom we conducted follow-up, we observed further clinical characteristics after treatment initiation. Most newly developed manifestations were reported within the first 2 weeks, but most patients recovered with persistent treatment (Appendix Figure 3). Two weeks after treatment initiation, 107 patients had newly developed cardiac inflammation, 112 neurobrucellosis, 140 urogenital inflammation, and 146 arthritis. Overall, 1,453 (86.7%) persons with acute brucellosis
symptomatically recovered within 180 days after appropriate treatment, whereas 223 (13.3%) were still symptomatic after 180 days and chronic brucellosis developed (Figure 1, panel B) (8). In the chronic phase, arthritis (89 [25.6%]), fatigue (60 [17.3%]), and fever (57 [16.4%]) became the 3 most common manifestations (Appendix Figure 4).

After conducting PSM for age, sex, nationality, and year of enrollment, we performed multivariate logistic regression to identify risk factors for chronic brucellosis in 148 acute cases and 148 chronic cases (Table 2). Fever, sweating, myalgia, arthritis, and C-reactive protein and erythrocyte sedimentation rates at baseline were possible predictors for chronic brucellosis in univariate analysis (p<0.10). Arthritis was the only risk factor after multivariate analysis (odds ratio 4.11 [95% CI 1.22–16.92]; p = 0.0318).

Dynamic SAT surveillance among 1,676 participants suggested that 53.8% (902/1,676) remained seropositive 42 days after treatment and 33.9% (518/1,676) remained seropositive 180 days after treatment (Figure 2, panel A). In acute cases, 413 remained seropositive and 1,040 seroconverted after 180 days. In chronic cases, 105 remained seropositive and 118 seroconverted (p<0.0001). The overall SAT titers decreased at the chronic phase; fewer patients had a titer of >1:400 (Figure 2, panel B).

We observed treatment outcomes in 432 patients without systemic involvement, of whom 307 (71.1%) received doxycycline and rifampin, 29 (6.7%) received doxycycline and levofloxacin, and 96 (22.2%) received triad therapy. In comparison with the standard 6-week treatment course (8–10), 75.2% (325/432) patients received antibiotic therapy for >42 days; median course of treatment was 90 (interquartile range 43–193) days (Figure 2, panel C). Further analysis in treatment elongation found that 26/325 (8.0%) were still symptomatic; the most common manifestations were sweating (61.5%), fatigue (50.0%), and fever (26.9%). A total of 174/325 (53.5%) participants were asymptomatic but seropositive, which could lead clinicians to subjectively extend antibiotic treatment; 125/325 (38.5%) participants were asymptomatic and

‡Information on age was available for 3,220 participants.
§Information on sex was available for 3,319 participants.
¶Information on nationality was available for 3,390 participants.
||Information on occupation was available for 3,369 participants.
#A total of 1,827 participants received Brucella culture, and 3,381 received SAT.
**Among 3,381 participants tested by SAT, 2,264 had detailed positive titer information.
seronegative (Figure 2, panel D). We further analyzed 107 participants who completed treatment within 42 days to determine whether standard treatment led to persistent symptoms or recurrence. Of those participants, 48/107 (44.9%) remained seropositive, 2/107 (1.9%) reported persistent symptoms, and 1/107 (0.9%) participant’s illness was considered a recurrence 2 years later.

The first limitation of our study is that we failed to follow up culture results during treatment. Second, we failed to distinguish transient and persistent exposure history, which might play a role in persistent symptoms or serologic results. Finally, infection was diagnosed by heterogenous methods, including culture and a series of serologic tests, which might introduce bias in baseline and prognosis analysis.

**Conclusions**

Our study gives a thorough, dynamic description of clinical characteristics and serologic surveillance during the natural history and treatment of human brucellosis in a large population. Culture was 23.2% positive but SAT 99.1% positive in confirmed brucellosis. SAT plus exposure history remained the most effective diagnostic tool. Human brucellosis had variable manifestations at different disease stages.

*CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; OR, odds ratio.
stages. Untreated cases mainly manifested as fatigue, fever, or sweating in the early stage, whereas fatigue, fever, and arthritis were the most common symptoms at the late stage. After appropriate treatment, 13.3% of acute brucellosis cases progressed to chronic disease. Arthritis can serve as an early predictor of chronic brucellosis. Seropositivity can persist after symptoms disappear, which might cause physicians to subjectively and unnecessarily extend therapeutic regimens.

Acknowledgments
We thank all the physicians that participated in this study for patient enrollment and follow-up and give our greatest appreciation to all health workers for their valuable input to the control of diseases.

This study was funded by Shanghai Municipal Science and Technology Major Project, Shanghai Key Laboratory of Infectious Diseases and Biosafety Emergency Response, Huashan Hospital, Fudan University (No. 20dz2260100, 21NL2600100, 20dz2210400), National Natural Science Foundation of China (no. 82002141), Shanghai Youth Science and Technology Talents Sailing Project (20YF1404300) and Key Discipline Construction Plan from Shanghai Municipal Health Commission (GWV-10.1-XK01, GWV-3.1, GWV-2).

The data that support the findings of this study are available from the corresponding author on reasonable request.

About the Author
Dr. H. Wang is a medical doctor in the Department of Infectious Diseases, Fudan University-affiliated Huashan Hospital, Shanghai, China. Her primary research interests are human brucellosis, severe pneumonia, and COVID-19.

Natural History and Dynamic Changes in Clinical Manifestation, Serology, and Treatment of Brucellosis, China

Appendix

Methods

Study Design

This is a multi-center, retrospective, real-world cohort study. Patients were recruited from September 2014 to December 2020 at 8 hospitals in Liaoning and Xinjiang Province, China, all of which are located in endemic areas of human brucellosis. All the patients enrolled were confirmed to be infected with brucellosis by meeting at least one of the following criteria according to the national guidelines (1): 1) positive culture of Brucella in blood or other sample; 2) positive ELISAs for IgG; 3) positive indirect Coomb's test with titers of >1:400, meanwhile showing significant agglutination; 4) positive complement fixation test (CFT) with titers of >1:10, meanwhile showing significant agglutination; 5) positive serum tube agglutination test (SAT) with titers of >1:100. The exclusion criteria included 1) incomplete medical history data; 2) positive HIV antibody and AIDS; 3) patients who participated in other clinical trials during the same period; 4) pregnant and lactating women or women of childbearing age who are ready to conceive.

The primary outcome of this study was the treatment duration and outcome (cured, dead, or on treatment) within 2 years after treatment. Main secondary outcomes included results of serologic tests, and patient status (cured, dead or on-treatment) at day 42 or day 180 after
treatment initiation. This study had been registered on ClinicalTrials.gov Protocol Registration and Results System (NCT04020536).

**Data Collection and Definitions**

Electronic health records were collected with a medical record system designed for real-world studies provided by Huashan Hospital across 8 centers. Basic information on epidemiologic exposure history, symptoms and signs, complications and comorbidities, pathogenic diagnosis data, laboratory test data, and antibiotic therapy on the first medical visit were collected. Symptom, serology, examination, laboratory test, antibiotic therapy variation was collected at 14, 28, 42, 90, 180, 360, and 720 days after treatment initiation, until follow-up reached 2 years or lost. Clinical symptoms, treatment course and outcomes, etc. were recorded according to the hospital information system. Additional surveys on the telephone were performed on day 42, 90, 180, 365 or 730 if patients did not come to the hospital for regular medical visits.

Systemic involvement of brucellosis was diagnosed based on combination of symptoms, physical examination, and radiographic imaging according to the guidelines. Arthritis was diagnosed based on radiologic examination including x-ray, computed tomography (CT), or magnetic resonance imaging (MRI). Urogenital inflammation was diagnosed based on physical examination and ultrasound. Cardiac inflammation including endocarditis and myocarditis was diagnosed based on echocardiography, cardiac enzyme, electrocardiogram, and differentiated with other heart disease. Neurobrucellosis was diagnosed based on physical examination, cerebrospinal fluid tests, cranial radiologic findings, and differentiated with other possible pathogens. Early phase is defined as the natural history of brucellosis with symptom duration <180 days before patients received antibiotic therapy, while late phase is defined as duration >180 days. Acute cases are defined as patients who symptomatically recover within 6 months of treatment. Chronic brucellosis is defined as brucellosis-associated symptoms persisting over 6-month treatment according to expert consensus in China (1). Recurrence is defined as the
reappearance of symptoms, or new positive blood cultures after treatment completed and clinical manifestations disappeared (2).

**Statistical Analysis**

Continuous variables were expressed as median (interquartile range) and compared with the Mann-Whitney U test; categorical variables were expressed as number (%) and compared by \( \chi^2 \) test or Fisher exact test. Symptoms, serology, and treatment variation was described with Kaplan-Meier curve and log-rank test. Propensity-score matching (PSM) was used to balance the difference between acute and chronic group, and risk factors were analyzed by logistic regression model. Two-tailed \( p<0.05 \) was considered statistically significant. Statistical analyses were performed using R software version 4.0.2. All figures were plotted by ggplot2 package.
