Abstract

Background

Postoperative nausea and vomiting (PONV) is a distressing complication of anesthesia and can lead to aspiration, dehydration, and electrolyte imbalance. Antiemetic agents are conventionally prescribed to manage PONV; however, they have associated side effects. Therefore, unconventional methods, such as auricular acupuncture (AA), are also utilized to prevent and control emesis after surgery. AA originated in traditional Chinese medicine and is based on a diagnostic and treatment system that aims to normalize dysfunction through stimulation of reflex points on the ear. The aim of this study is to evaluate the effects of AA in controlling PONV.

Methods

We will perform a systematic review according to the Cochrane methodology. An overall search strategy will be developed and adapted for PubMed, PEDro, the Virtual Health Library, SciELO, EMBASE, the Web of Science, SciVerse Scopus, and the Cochrane Library to search for the following descriptors: “Acupressure”; “Antiemetics”; “Postoperative nausea and vomiting”; “Surgery”; “Auriculotherapy”; “Nausea”; “Vomiting”; and “Postoperative period.” Articles with a mean score of 6 ± 1.5 on the PEDro scale will be evaluated. The size of the intervention effect (Z) will be calculated for each outcome included in this review. The primary outcome will be the incidence of PONV. The secondary outcome will be the severity of PONV. Quality assessment will be performed with the Cochrane instrument. If possible, a meta-analysis will be performed using Review Manager 5.3 software.

Discussion

Several studies have reported positive outcomes of AA for patients with PONV. This study could provide robust and conclusive evidence of the usefulness of AA as an effective treatment alternative for emesis without the side effects of conventional medication.

Trial registration

Systematic review registration number: CRD42020149772 (S1 File)

Background

In the postoperative period of surgical intervention under anesthesia, emesis is a side effect, characterized by nausea and vomiting [1, 2]. The incidences of nausea and vomiting after surgery under anesthesia are 50% and 30%, respectively [3]. Patient-controlled analgesics, such as morphine, provide pain relief but can also induce postoperative nausea and vomiting (PONV). Emesis can lead to aspiration,
dehydration, and electrolyte imbalance [4], thereby compromising the patient’s quality of life and adherence to treatment and increasing the length of hospital stay, hindering the return to activities of daily living [1, 2].

Drugs to treat emesis act on type 3 serotonin, muscarinic, type 2 dopamine, and opioid receptors [5]. Antiemetic medications can elevate blood glucose levels [6] and cause other adverse effects, such as hypotension, hypertension, dysphoria, hallucinations, excessive sedation, dry mouth, psychological disturbances, or pyramidal symptoms [7, 8]. Therefore, there is a need for alternative methods, such as auricular acupuncture, that have fewer side effects are aimed at replacing antiemetic medications [9].

In the past four decades, acupuncture has become widespread at occidental health care centers. For pain relief, scientific studies have shown acupuncture to be effective. Acupuncture is an old medical treatment that originated in China [8], and auricular acupuncture is a subtype that involves stimulation of ear acupoints. There are 93 specific points identified for auriculotherapy, which are located in and around the ear. These points can be subjected to needle stimulation, ear acupressure with seeds or pallets, laser stimulation, or electrostimulation [10]. The World Health Organization has presented a list of medical conditions for which acupuncture can have positive results, including the prevention and treatment of PONV [11]. However, the effects of this technique on postoperative patients have not been fully elucidated.

Since emesis is a common side effect after surgery and auricular acupuncture is an alternative treatment method, the aim of this study is to review the effects of this technique on the control of PONV.

**Methods/design**

**Type of study**

We will conduct a systematic review of the literature with meta-analysis (if possible) on the effects of complementary therapy in the reduction of nausea and vomiting in the study population based on the PRISMA Statement recommendations [12] (S2 File). This study is directly related to human health.

**Eligibility criteria**

Available data will be searched in relevant international journals in English, Portuguese, Spanish, and Mandarin with previously defined criteria according to the PICOS acronym (Population, Intervention, Comparison, Outcome, and Study type).

**Population**

Patients in the early postoperative period after surgical intervention under anesthesia who presented with emesis (nausea and vomiting) will be included in this systematic review.

**Intervention**
Studies that used an ear acupoint acupuncture to reduce or control emesis in patients after surgical interventions will be analyzed. Applications of the following types will be considered: transcutaneous electrical nerve stimulation, needles, seeds or pallets, and laser electrostimulation.

Comparison

Only studies that compared an experimental group with a control group of placebo or other interventions will be included.

Outcomes

Primary outcomes

The primary outcome will be the occurrence of nausea and vomiting in the postoperative period. Emesis will be considered in the absence of distinction between nausea and vomiting.

Secondary outcomes

The secondary outcome will be the severity of PONV.

Search strategy

The search terms for the research databases, selected from Medical Subject Headings and Health Sciences descriptors, are as follows: “Acupressure”; “Antiemetics”; “Postoperative nausea and vomiting”; “Surgery”; “Auriculotherapy”; “Nausea”; “Vomiting”; and “Postoperative period.” A search strategy model will be developed for PubMed, PEDro, the Virtual Health Library, SciELO, EMBASE, the Web of Science, SciVerse Scopus, and the Cochrane Library. Studies published every year up to 2021 will be searched.

Study selection

For the initial selection, studies that do not address the topic will be excluded. Two reviewers will perform a secondary selection to eliminate irrelevant studies. The order of the review will be as follows: title, abstract, and full reading (Fig.1). All studies potentially eligible for inclusion in the review will be selected for full reading. In cases of disagreement, a third reviewer will be consulted.

Figure 1. Study Selection for Review.

Study quality assessment

The qualification of the methodology used in the research will be analyzed using PEDro.

Selected information

Eligible studies will undergo a data extraction and management step. A standardized form will be used to guide the extraction of the following information: population, intervention group (acupoints used),
comparison group (proposed protocol), outcome, and type of study. Studies that do not fully meet the inclusion criteria will be excluded and tabulated with their justification for the exclusion shown in table 1. The characteristics of the selected studies will be presented as shown in table 2.

Table 1. Study characteristics related to the number of participants, inclusion, and exclusion criteria.

| Author / Year | No. of participants | Inclusion criteria | Exclusion criteria |
|---------------|---------------------|--------------------|-------------------|
|               |                     |                    |                   |

Table 2. Study Characteristics related to the configuration.

| Title / Author/ Year | Signs and Symptoms | No. of participant per group | Definition of Auriculo therapy (protocol details) | Comparison groups | Outcome | Results | PEDro |
|----------------------|--------------------|------------------------------|-------------------------------------------------|-------------------|---------|---------|--------|
|                      |                    |                              |                                                 |                   |         |         |        |

The methodological quality, risk of bias, and statistical report will be assessed on the PEDro scale for the risk of bias using the following parameters: concealment of allocation, allocation generation, masking (of participants and researchers), the presence of incomplete data, and reporting biases of information or other types. The answers to these domains can be “Yes,” “No,” or “Where” [13]. The score will only be awarded when a criterion is clearly satisfied. Moreover, the recommendations of the Preferred Report Items for Systematic Reviews and PRISMA statement will be followed [14].

Rayyan is a web-enabled application that helps authors of systematic reviews optimize the study development process. The software helps include and exclude articles using the abstract, title, filters, keywords, authors, year of publication, and label. Another advantage of Rayyan is the ability to have multiple blind collaborators work on the same review. In this study, three reviewers will be used for the impartial selection of articles [15].

Results regarding the study population will be presented as descriptive. The size of the intervention effect (Z) will be calculated for each study included in this review using the mean difference or standardized mean difference. For data with low heterogeneity, a meta-analysis of fixed effects will be performed to estimate the effect of treatment on patients with PONV. For data with high heterogeneity, a random-effects model will be utilized. The absence of publication bias will be analyzed using a funnel plot. $P$-value $<0.05$ will be set as statistical significance. Review Manager software will be used for all analyses, including the meta-analysis if possible [16].
Discussion

Previous studies have shown auriculotherapy as an alternative or complementary option for antiemetics to manage PONV. Nevertheless, there are controversies and a lack of consensus in the literature regarding the methodologies and results of this therapy.

Although there are currently several study formats in the literature related to the understanding of the auricular acupuncture effects in postoperative emesis (whether qualitative or quantitative), this study design seeks to highlight the main points of randomized and nonrandomized clinical trials, thus evaluating the available evidence with better methodological precision. This systematic review (and meta-analysis, if feasible) is aimed at systematizing the various effects and possible results of this technique.

This study could provide clear and robust evidence regarding the usefulness of ear acupuncture to treat postoperative emesis in addition to a consensus of methodology that would warrant the success of this alternative therapy. Further, it could pave the way for high-quality future studies on the subject.

Limitations

This systematic review with meta-analysis may be limited if there is a scarcity of studies in the literature, heterogeneity of experimental protocols and absence of data from studies for analysis, methodological quality of the studies.

Abbreviations

PONV - Postoperative nausea and vomiting

AA - Auricular acupuncture

Z - The size of the intervention effect
