Multijet production in neutral current deep inelastic scattering at HERA and determination of $\alpha_s$

ZEUS Collaboration

Abstract

Multijet production rates in neutral current deep inelastic scattering have been measured in the range of exchanged boson virtualities $10 < Q^2 < 5000 \text{ GeV}^2$. The data were taken at the $ep$ collider HERA with centre-of-mass energy $\sqrt{s} = 318 \text{ GeV}$ using the ZEUS detector and correspond to an integrated luminosity of $82.2 \text{ pb}^{-1}$. Jets were identified in the Breit frame using the $k_T$ cluster algorithm in the longitudinally invariant inclusive mode. Measurements of differential dijet and trijet cross sections are presented as functions of jet transverse energy ($E_{T,B}^{\text{jet}}$), pseudorapidity ($\eta_{LAB}^{\text{jet}}$) and $Q^2$ with $E_{T,B}^{\text{jet}} > 5 \text{ GeV}$ and $-1 < \eta_{LAB}^{\text{jet}} < 2.5$. Next-to-leading-order QCD calculations describe the data well. The value of the strong coupling constant $\alpha_s(M_Z)$, determined from the ratio of the trijet to dijet cross sections, is $\alpha_s(M_Z) = 0.1179 \pm 0.0013 \text{ (stat.)}^{+0.0028}_{-0.0046} \text{ (exp.)}^{+0.0064}_{-0.0046} \text{ (th.)}$.

1 Introduction

Measurements of multijet production from initial-state hadrons and leptons have been carried out previously in collisions at the SPS [1], the ISR [2], the TEVATRON [3] and at LEP [4] as well as in photoproduction [5] and deep inelastic scattering (DIS) [6] at HERA. Multijet production in DIS at HERA has been used to test the predictions of perturbative QCD (pQCD) calculations over a large range of four-momentum transfer squared, $Q^2$ [7]. Recently, the ZEUS and H1 collaborations have determined the strong coupling constant $\alpha_s$ from a variety of measurements of jet production and jet properties in both DIS [6, 8–14] and photoproduction [15].

At leading order (LO) in $\alpha_s$, dijet production in neutral current DIS proceeds via the boson-gluon-fusion (BGF, $V^*g \rightarrow q\bar{q}$ with $V = \gamma, Z^0$) and QCD-Compton (QCDC, $V^*q \rightarrow qg$) processes. Events with three jets can be seen as dijet processes with an additional gluon radiation or splitting of a gluon into a quark-antiquark pair and are directly sensitive to $O(\alpha_s^2)$ QCD effects. The higher sensitivity to $\alpha_s$ and the large number of degrees of freedom of the trijet final state allow detailed testing of QCD predictions.

In the present analysis, the differential cross sections for the trijet production have been measured with high statistical precision. Measurements of the inclusive trijet cross section as a function of $Q^2$ and the jet transverse energy, $E_{T,B}^{\text{jet}}$, in the Breit frame and the jet pseudorapidity, $\eta_{\text{LAB}}^{\text{jet}}$, in the laboratory frame are presented. Predictions of pQCD at next-to-leading order (NLO) are compared to the measurements. In addition, the analysis includes the first $\alpha_s$ determination using the cross-section ratio of trijet to dijet production, $R_{3/2}$, at HERA. In this ratio, correlated experimental and theoretical uncertainties cancel, allowing for an extension of the measurement to low $Q^2$.

2 Experimental set-up

The data used in this analysis were collected during the 1998-2000 running period, when HERA operated with protons of energy $E_p = 920$ GeV and electrons or positrons\(^1\) of energy $E_e = 27.5$ GeV, and correspond to an integrated luminosity of $82.2 \pm 1.9$ pb\(^{-1}\). A detailed description of the ZEUS detector can be found elsewhere [16,17]. A brief outline of the components that are most relevant for this analysis is given below.

Charged particles are measured in the central tracking detector (CTD) [18], which operates in a magnetic field of 1.43 T provided by a thin superconducting solenoid. The CTD consists of 72 cylindrical drift chamber layers, organised in nine superlayers covering the

\(^1\) In the following, the term “electron” denotes generically both the electron ($e^-$) and the positron ($e^+$).
polar-angle\(^2\) region \(15^\circ < \theta < 164^\circ\). The transverse momentum resolution for full-length tracks can be parameterised as \(\sigma(p_T)/p_T = 0.0058 p_T + 0.0065 + 0.0014/p_T\), with \(p_T\) in GeV. The tracking system was used to measure the interaction vertex with a typical resolution along (transverse to) the beam direction of 0.4 (0.1) cm and also to cross-check the energy scale of the calorimeter.

The high-resolution uranium-scintillator calorimeter (CAL) [19] covers 99.7\% of the total solid angle and consists of three parts: the forward (FCAL), the barrel (BCAL) and the rear (RCAL) calorimeters. Each part is subdivided transversely into towers and longitudinally into one electromagnetic section (EMC) and either one (in RCAL) or two (in BCAL and FCAL) hadronic sections (HAC). The smallest subdivision of the calorimeter is called a cell. Under test-beam conditions, the CAL single-particle relative energy resolutions were \(\sigma(E)/E = 0.18/\sqrt{E}\) for electrons and \(\sigma(E)/E = 0.35/\sqrt{E}\) for hadrons, with \(E\) in GeV.

The luminosity was measured from the rate of the bremsstrahlung process \(ep \to e\gamma p\). The resulting small angle energetic photons were measured by the luminosity monitor [20], a lead-scintillator calorimeter placed in the HERA tunnel at \(Z = -107\) m.

### 3 Kinematics and event selection

A three-level trigger system was used to select events online [17,21–23]. Neutral current DIS events were selected by requiring that the scattered electron with energy more than 4 GeV was measured in the CAL [24].

The offline kinematic variables \(Q^2\) (four-momentum transfer squared), \(x_{Bj}\) (Bjorken scaling variable) and \(y = Q^2/(sx_{Bj})\) (\(s\) is the centre-of-mass energy squared) were reconstructed by the electron (e), double angle (DA) [25] and Jacquet-Blondel (JB) [26] methods. The angle of the hadronic system, \(\gamma_{had}\), corresponds, in the quark-parton model, to the direction of the scattered quark and was reconstructed from the CAL measurements of the hadronic final state.

If \(\gamma_{had}\) was less than 90\(^\circ\) and the scattered-electron track could be well reconstructed by the CTD, the DA method was used; otherwise, the electron method was used. The offline selection of DIS events was similar to that used in a previous ZEUS measurement [27] and was based on the following requirements:

---

\(^2\) The ZEUS coordinate system is a right-handed Cartesian system, with the Z axis pointing in the proton beam direction, referred to as the “forward direction”, and the X axis pointing left towards the centre of HERA. The coordinate origin is at the nominal interaction point.
• $E'_e > 10 \text{ GeV}$, where $E'_e$ is the scattered-electron energy after correction for energy loss in inactive material in front of the CAL, to achieve a high-purity sample of DIS events;

• $y_e < 0.6$, where $y_e$ is $y$ reconstructed by the electron method, to reduce the photoproduction background;

• $y_{JB} > 0.04$, where $y_{JB}$ is $y$ reconstructed by the JB method, to ensure sufficient accuracy for the DA reconstruction of $Q^2$;

• $\cos \gamma_{\text{had}} < 0.7$, to ensure good reconstruction of jets in the Breit frame;

• $40 < \sum_i (E - P_Z)_i < 60 \text{ GeV}$, where the sum runs over all CAL energy deposits. The lower cut removed background from photoproduction and events with large initial-state QED radiation. The higher cut removed cosmic-ray background;

• $|Z_{\text{vertex}}| < 50 \text{ cm}$, where $Z_{\text{vertex}}$ is the reconstructed primary vertex $Z$-position, to select events consistent with $ep$ collisions;

• $|X| > 13$ or $|Y| > 7 \text{ cm}$, where $X$ and $Y$ are the impact positions of the scattered electron on the RCAL, to avoid the low-acceptance region adjacent to the rear beampipe.

The kinematic range of the analysis is defined as:

$$10 < Q^2 < 5000 \text{ GeV}^2 \text{ and } 0.04 < y < 0.6.$$
4 Monte Carlo simulation

Monte Carlo (MC) simulations were used to correct the data for detector effects, inefficiencies of the event selection and that of the jet reconstruction, as well as for QED effects. Neutral current DIS events were generated using the ARIADNE 4.08 program [33] and the LEPTO 6.5 program [34] interfaced to HERACLES 4.5.2 [35] via DJANGO 6.2.4 [36]. The HERACLES program includes QED effects up to $O(\alpha^2_{\text{EM}})$. In case of ARIADNE, the QCD cascade is simulated using the colour-dipole model [37], whereas for LEPTO, the matrix elements plus parton shower model is used. Both models use the Lund string model [38], as implemented in JETSET 7.4 [39, 40], for hadronisation.

The ZEUS detector response was simulated with a program based on GEANT 3.13 [41]. The generated events were passed through the detector simulation, subjected to the same trigger requirements as the data, and processed by the same reconstruction and offline programs.

Measured distributions of kinematic variables are well described by both the ARIADNE and LEPTO MC models after reweighting in $Q^2$. The LEPTO simulation gives a better overall description of the $E_{T,B}^{\text{jet}}$ and invariant mass distributions. Therefore, the events generated with the LEPTO program were used to determine the acceptance corrections. The events generated with ARIADNE were used to estimate the systematic uncertainty associated with the treatment of the parton shower.

5 NLO QCD calculations

The NLO calculations were carried out in the $\overline{\text{MS}}$ scheme for five massless quark flavors with the program NLOJET [42] using CTEQ6 [43], CTEQ4 [44], MRST99 [45] and ZEUS-S [46] for the proton parton density functions (PDFs). NLOJET allows a computation of the trijet production cross sections to next-to-leading order, i.e. including all terms up to $O(\alpha^3_s)$. It was checked that the LO and NLO calculations from NLOJET agree with those of DISENT [47] at the 1-2% level for the dijet cross sections [22, 23].

For comparison with the data, the CTEQ6 parameterisations of the proton PDFs were used and the renormalisation and factorisation scales were both chosen to be $\langle \tilde{E}_T^2 + Q^2 \rangle / 4$, where for dijets (trijets) $\tilde{E}_T$ is the average $E_T$ of the two (three) highest $E_T$ jets in a given event. The strong coupling constant was set to the value used in the CTEQ6 analysis, $\alpha_s(M_Z) = 0.1179$, and evolved according to the two-loop solution of the renormalisation group equation.

The NLO QCD predictions were corrected for hadronisation effects using a bin-by-bin procedure. Hadronisation correction factors were defined for each bin as the ratio of the
parton- to hadron-level cross sections and were calculated using the LEPTO MC program. The correction factors $C_{\text{had}}$ were typically in the range $1.15 - 1.35$ for most of the phase space.

6 Corrections and systematic uncertainties

The jet transverse energy was corrected for energy losses in the inactive material in front of the CAL using the samples of MC simulated events [14]. The cross sections for jets of hadrons in bins of $Q^2$, $E_{T,B}^{\text{jet}}$ and $\eta_{\text{LAB}}^{\text{jet}}$ were obtained by applying a bin-by-bin correction to the measured jet distributions using the LEPTO program. The corrections take into account the efficiency of the trigger, the selection criteria and the purity and efficiency of the jet reconstruction. Additional corrections for QED effects, $C_{\text{QED}}$, calculated using HERACLES, were applied to the measured cross sections, $\sigma_{\text{Born}} = \sigma_{\text{meas}} \cdot C_{\text{QED}}$.

A detailed study of the sources contributing to the systematic uncertainties of the measurements was performed [22,23]. The main sources contributing to the systematic uncertainties are listed below (typical values of the systematic uncertainties in the dijet cross section and cross-section ratio $R_{3/2}$ are indicated in parentheses):

- **jet-pseudorapidity cut** - a change of $\pm 0.1$ (corresponding to the resolution) in the $\eta_{\text{LAB}}^{\text{jet}}$ cuts imposed on the jets in the laboratory frame for both data and MC simulated events (1%,1%);

- **jet transverse energy and invariant mass cuts** - $E_{T,B}^{\text{jet}}$ and $M_{2\text{jets}}$($M_{3\text{jets}}$) were simultaneously varied by the corresponding resolution near the cuts for both data and MC simulated events. Along with the previous systematic check, this takes into account the effect of the remaining differences between the data and the MC simulation (3%,3%);

- **use of different parton shower model** - using ARIADNE instead of LEPTO to evaluate the acceptance corrections (2%,4%);

- **the absolute energy scale of the CAL** - varying $E_{T,B}^{\text{jet}}$ by its uncertainty of $\pm 1\%(>10 \text{ GeV})$ and $\pm 3\%(<10 \text{ GeV})$ for MC events [10] (6%,3.5%).

The systematic uncertainties not associated with the absolute energy scale of the CAL were added in quadrature to the statistical uncertainties and are shown on the figures as error bars. The uncertainty due to the absolute energy scale of the CAL is highly correlated from bin-to-bin and is shown separately as a shaded band. The total systematic uncertainty and the uncertainty due to the absolute energy scale are also shown in Tables 1-9.

The main contributions to the theoretical uncertainties of the NLO QCD predictions are:
• uncertainties in the proton PDFs, which were estimated by repeating the calculations using 40 additional sets obtained under different theoretical assumptions as part of the CTEQ6 release (2.5%, 2%);

• uncertainties in the correction factors, $C_{\text{had}}$, which were estimated by using the Ariadne program instead of Lepto (6%, 4%);

• uncertainties due to terms beyond NLO, which were estimated by varying both $\mu_R$ and $\mu_F$ between $(\bar{E}_T^2 + Q^2)$ and $(\bar{E}_T^2 + Q^2)/16$ (10%, 7%).

The total theoretical uncertainty was obtained by adding in quadrature the individual uncertainties listed above.

7 Results

7.1 Differential cross sections

The differential trijet cross sections as functions of $E_{T,B}^{\text{jet}}$ are presented in Fig. 1 and in Tables 1–3. The three highest $E_{T,B}^{\text{jet}}$ jets were ordered in $E_{T,B}^{\text{jet}}$ ($E_{T,B}^{\text{jet},1} > E_{T,B}^{\text{jet},2} > E_{T,B}^{\text{jet},3}$). The observed decrease of the cross section for the first jet towards small values of $E_{T,B}^{\text{jet}}$ is caused by the $E_{T,B}^{\text{jet}}$ ordering combined with the requirement that the second and third jet have $E_{T,B}^{\text{jet}}>5$ GeV. For the second jet, a similar but less pronounced effect is observed. The NLO predictions using NLOjet, corrected for hadronisation effects, are compared to the data in Fig. 1. The QCD predictions provide a good description of both the shape and magnitude of the measured cross sections, even at low $E_{T,B}^{\text{jet}}$.

Figure 2 and Tables 4–6 show the differential trijet cross sections as functions of $\eta_{\text{LAB}}^{\text{jet}}$. The three highest $E_{T,B}^{\text{jet}}$ jets were ordered in $\eta_{\text{LAB}}^{\text{jet}}$ ($\eta_{\text{LAB}}^{\text{jet},1} > \eta_{\text{LAB}}^{\text{jet},2} > \eta_{\text{LAB}}^{\text{jet},3}$). Figure 3 and Tables 7 and 8 show both the differential dijet and trijet cross section as functions of $Q^2$. In Figs. 2 and 3, the data are generally well described by the NLO QCD predictions. The largest difference is a slightly different slope of the $\eta_{\text{LAB}}^{\text{jet}}$ dependence of the third jet.

7.2 Cross-section ratio and determination of $\alpha_s$

Figure 4 and Table 9 show the cross-section ratio $R_{3/2}$ of the trijet cross section to the dijet cross section, as a function of $Q^2$. The correlated systematic and the renormalisation scale uncertainties largely cancel in the ratio. The agreement between the data and NLO predictions is good. The total experimental and theoretical uncertainties are about 5% and 7%, respectively. These uncertainties are substantially reduced with respect to those of the di- and trijet cross sections. In particular, at low $Q^2$ ($Q^2 < 100$ GeV$^2$), the
theoretical uncertainties are reduced by as much as a factor of four. This reduction allows the determination of $\alpha_s(M_Z)$ at a much lower $Q^2$ than in previous analyses \cite{10, 14}.

The measurement of $R_{3/2}$ as a function of $Q^2$ was used to determine $\alpha_s(M_Z)$ with a method similar to that of a previous ZEUS publication \cite{9}:

- the NLO QCD calculation of $R_{3/2}$ was performed using the five sets of proton PDFs of the CTEQ4 A-series \cite{44} \textsuperscript{3}. The value of $\alpha_s(M_Z)$ used in each partonic cross-section calculation was that associated with the corresponding set of PDFs: 0.110, 0.113, 0.116, 0.119, 0.122;
- for each bin, $i$, in $Q^2$, the NLO QCD calculations, corrected for hadronisation effects, were used to parameterise the $\alpha_s(M_Z)$ dependence of $R_{3/2}$ according to the functional form:

$$[R_{3/2}(\alpha_s(M_Z))] = C^i_1 \cdot \alpha_s(M_Z) + C^i_2 \cdot \alpha^2_s(M_Z),$$

(1)

where $C^i_1$ and $C^i_2$ are fitting parameters. This simple parameterisation gives a good description of the $\alpha_s(M_Z)$ dependence of $R_{3/2}(Q^2)$ over the entire $\alpha_s$ range spanned by the PDF sets;
- a value of $\alpha_s(M_Z)$ was then determined in each bin of $Q^2$, as well as in the entire $Q^2$ region, by a $\chi^2$-fit of the measured $R_{3/2}(Q^2)$ values using the parameterisation in Eq. (1).

This procedure correctly handles the complete $\alpha_s$-dependence of the NLO differential cross sections (the explicit dependence coming from the partonic cross sections and the implicit dependence coming from the PDFs) in the fit, while preserving the correlation between $\alpha_s$ and the PDFs. Taking into account only the statistical uncertainties on the measured cross-section ratio, $\alpha_s(M_Z)$ is determined to be $\alpha_s(M_Z) = 0.1179 \pm 0.0013$ (stat.).

Figure 5a shows the sensitivity of the cross-section ratio $R_{3/2}$ to the value of $\alpha_s$. Figure 5b and Table 10 show $\alpha_s(M_Z)$ determined in the five bins of $Q^2$.

As a cross-check of the extracted value of $\alpha_s(M_Z)$, the fit procedure was repeated by using the three sets of the MRST99 PDF corresponding to $\alpha_s(M_Z)$ equal to 0.1125, 0.1175 and 0.1225. The result is $\alpha_s(M_Z) = 0.1178 \pm 0.0010$ (stat.).

In addition, the NLO QCD analysis used to obtain the ZEUS-S PDF \cite{46} was repeated to obtain a set of five PDFs corresponding to the values of $\alpha_s(M_Z)$: 0.115, 0.117, 0.119, 0.121, 0.123. These sets were used in the current analysis yielding $\alpha_s(M_Z) = 0.1191 \pm 0.0010$ (stat.), in good agreement with the other determinations.

\textsuperscript{3}The CTEQ4 PDF was chosen because the CTEQ6 does not provide PDF sets obtained with different $\alpha_s(M_Z)$ values and therefore cannot be used for the determination of $\alpha_s$. 

The experimental and theoretical uncertainties of the extracted value of $\alpha_s(M_Z)$ were evaluated by repeating the analysis above for each systematic check, as described in Section 6. The main contributions to the experimental systematic uncertainty were:

- jet pseudorapidity cut ($^{+1\%}_{-1.5\%}$);
- jet transverse energy and invariant mass cuts ($^{+0.5\%}_{-2\%}$);
- use of different parton shower model ($^{+2\%}_{-2\%}$);
- the absolute energy scale of the CAL ($^{+2\%}_{-2.5\%}$).

The main contributions to the theoretical uncertainty are:

- uncertainties in the proton PDFs ($^{+1.5\%}_{-2\%}$);
- uncertainties in the correction factor, $C_{\text{had}}$ ($^{+2\%}$);
- uncertainties due to terms beyond NLO ($^{+5\%}_{-3.5\%}$).

The value of $\alpha_s(M_Z)$ as determined from the measurements of $R_{3/2}$ is therefore:

$$\alpha_s(M_Z) = 0.1179 \pm 0.0013 \ (\text{stat.})^{+0.0028}_{-0.0046} \ (\exp.)^{+0.0064}_{-0.0046} \ (\text{th.}).$$

The result is in good agreement with recent determinations at HERA [6, 8–15] and the current world average of $\alpha_s(M_Z) = 0.1182 \pm 0.0027$ [48].

### 8 Summary

Differential dijet and trijet cross sections have been measured with high precision in neutral current deep inelastic scattering for $10 < Q^2 < 5000 \text{ GeV}^2$ at HERA using the ZEUS detector. The inclusive trijet cross section has been measured as a function of $E_{T,B}^{\text{jet}}$, $\eta_{LAB}^{\text{jet}}$ and $Q^2$. The ratio $R_{3/2}$ of the trijet and dijet cross sections has been measured as a function of $Q^2$. The predictions of perturbative QCD calculations in next-to-leading order give a good description of the dijet and trijet cross sections and the cross-section ratio $R_{3/2}$ over the whole range of $Q^2$. The cancellation of uncertainties in the ratio, in particular those from theory, allow the extraction of $\alpha_s$ with good precision down to $Q^2$ of 10 GeV$^2$. The value of the strong coupling constant $\alpha_s$ was measured to be $\alpha_s(M_Z) = 0.1179 \pm 0.0013 \ (\text{stat.})^{+0.0028}_{-0.0046} \ (\exp.)^{+0.0064}_{-0.0046} \ (\text{th.})$, in good agreement with the current world average value and previous determinations of $\alpha_s(M_Z)$ at HERA.

### 9 Acknowledgements

We thank the DESY Directorate for their strong support and encouragement. The remarkable achievements of the HERA machine group were essential for the successful
completion of this work and are greatly appreciated. The design, construction and installation of the ZEUS detector has been made possible by the effort of many people who are not listed as authors. We would like to thank Z. Nagy for useful discussions.

Table 1: The inclusive trijet cross section $d\sigma/dE_{T,B}^{\text{jet},1}$ for jets of hadrons in the Breit frame, selected using the $k_T$ cluster algorithm in the longitudinally invariant inclusive mode. The statistical ($\delta_{\text{stat}}$), systematic ($\delta_{\text{syst}}$) and the absolute energy scale uncertainties ($\delta_{\text{ES}}$) are shown separately. The multiplicative correction factors for QED radiative effects ($C_{\text{QED}}$), applied to the data, and for hadronisation effects ($C_{\text{had}}$), applied to the NLO predictions, are shown in the last two columns.

| 10 - 5000       | 0.1179          | ± 0.0013       | +0.0028        | +0.0064        |
Figure 1: (a) The inclusive trijet cross sections as functions of $E_{T,B}^{jet}$ with the jets ordered in $E_{T,B}^{jet}$. The cross sections of the second and third jet were scaled by the factors shown for readability. The inner error bars represent the statistical uncertainties. The outer error bars represent the quadratic sum of statistical and systematic uncertainties not associated with the calorimeter energy scale. The shaded band indicates the calorimeter energy scale uncertainty. The predictions of perturbative QCD in next-to-leading order, corrected for hadronisation effects and using the CTEQ6 parameterisations of the proton PDFs, are compared to the data. (b), (c) and (d) show the ratio of the data to the predictions. The hatched band represents the renormalisation scale uncertainty of the QCD calculation.
Figure 2: (a) The inclusive trijet cross sections as functions of $\eta_{\text{LAB}}^{\text{jet}}$ with the jets ordered in $\eta_{\text{LAB}}^{\text{jet}}$. The cross sections of the second and third jet were scaled up for readability only. The predictions of perturbative QCD in next-to-leading order are compared to the data. (b), (c) and (d) show the ratio of the data to the predictions. Other details are as in the caption to Fig. 1.
Figure 3:  (a) The inclusive dijet and trijet cross sections as functions of $Q^2$. The predictions of perturbative QCD in next-to-leading order are compared to the data. (b) and (c) show the ratio of the data to the predictions. Other details are as in the caption to Fig. 1.
Figure 4: (a) The ratio of inclusive trijet to dijet cross sections as a function of $Q^2$. The predictions of perturbative QCD in next-to-leading order are compared to the data. (b) shows the ratio of the data to the predictions. Other details are as in the caption to Fig. 1.
Figure 5:  (a) The ratio of inclusive trijet to dijet cross sections as a function of $Q^2$. The predictions of perturbative QCD in next-to-leading order using five sets of CTEQ4 PDF are compared to the data. (b) shows the $\alpha_s(M_Z)$ values determined from the ratio of inclusive trijet to dijet cross sections in different regions of $Q^2$. The shaded band indicates the current world average value of $\alpha_s(M_Z)$. The inner error bars represent the statistical uncertainty of the data. The outer error bars show the statistical and systematic uncertainties added in quadrature. The dashed error bars display the theoretical uncertainties.
