JUSTIFICATION OF GALERKIN AND COLLOCATIONS METHODS FOR ONE CLASS OF SINGULAR INTEGRO-DIFFERENTIAL EQUATIONS ON INTERVAL

A.I. FEDOTOV

Abstract. We justify the Galerkin and collocations methods for one class of singular integro-differential equations defined on the pair of the weighted Sobolev spaces. The exact solution of the considered equation is approximated by the linear combinations of the Chebyshev polynomials of the first kind. According to the Galerkin method, we equate the Fourier coefficients with respect to the Chebyshev polynomials of the second kind in the right-hand side and the left-hand side of the equation. According to collocations method, we equate the values of the right-hand side and the left-hand side of the equation at the nodes being the roots of the Chebyshev polynomials the second kind.

The choice of the first kind Chebyshev polynomials as coordinate functions is due to the possibility to calculate explicitly the singular integrals with Cauchy kernel of the products of these polynomials and corresponding weight functions. This allows us to construct simple well converging methods for the wide class of singular integro-differential equations on the interval (−1, 1).

The Galerkin method is justified by the Gabdulkhaev–Kantorovich technique. The convergence of collocations method is proved by the Arnold–Wendland technique as a consequence of convergence of the Galerkin method. Thus, the convergence of both methods is proved and effective estimates for the errors are obtained.

Keywords: singular integro-differential equations, justification of approximate methods.

Mathematics Subject Classification: 65R20

1. INTRODUCTION

Considering the current state-of-art of the theory of approximate methods for solving singular integro-differential equations in the periodic and non-periodic cases, it can be stated that while in the periodic case this theory is almost completed, in the non-periodic case one succeed to obtain only particular results [1]–[6] for the first order equations. The reason for this situation, in particular, is an essential difference between the properties of singular integrals with the Hilbert and Cauchy kernels. And while in the periodic case the systems of orthogonal trigonometric polynomials allow one to develop and justify simple computational schemes for singular integro-differential equations of any order including a fractional one, see, for example, [7], in the non-periodic case all computational schemes are constructed on the basis of two well-known formulae for singular integrals of Chebyshev polynomials of the first and second kind [8] and therefore, only problems of the first order are treated. An only exception is the work by the author [9]. But in this work a lack in the theory of approximate methods for

such equations also made us to introduce strict artificial restrictions for the coefficients of the
equations to ensure the convergence of the method.

In the present work, being a continuation of work [6], we justify the Galerkin method and
collocation method for singular integro-differential equations from a much wider class than
one considered in [6]. The justification of the Galerkin method is made by employing a
Gabdulkhaev-Kantorovich technique, see, for instance, [10]. The collocation method is jus-
tified as a corollary of the convergence of the Galerkin method by Arnold-Wendland approach
[11]. We prove the convergence of both methods and obtain effective estimates for the errors.

2. Main definitions and notations

As usually, by \( \mathbb{N} \) we denote the set of natural numbers, \( \mathbb{N}_0 \) is the set of the natural numbers
with the zero, and \( \mathbb{R} \) is the set of real numbers. We denote by
\[
p(t) = (1 - t^2)^{-\frac{1}{2}}, \quad q(t) = (1 - t^2)^{\frac{1}{2}}, \quad t \in (-1, 1),
\]
the weight functions corresponding to the Chebyshev polynomials of the first kind
\[
T_l(t) = \cos(l \arccos t), \quad l \in \mathbb{N}_0, \quad t \in (-1, 1),
\]
and to the Chebyshev polynomials of the second kind
\[
U_l(t) = \frac{\sin(l \arccos t)}{\sin(\arccos t)}, \quad l \in \mathbb{N}, \quad t \in (-1, 1).
\]

We denote by \( H^{s+1}_p \) the Sobolev space of order \( s + 1 \in \mathbb{R} \) with a weight \( p \), that is, the closure
of the set of polynomials \( \{T_l\}_{l \in \mathbb{N}_0} \) with respect to the norm
\[
\|x\|_{H^{s+1}_p} = \left\{ \sum_{l \in \mathbb{N}_0} l^{2(s+1)} \hat{x}^2 \left( l, -\frac{1}{2} \right) \right\}^{1/2}, \quad l = \begin{cases} l, & l \in \mathbb{N}, \\ 1, & l = 0, \end{cases}
\]
\[
(2.1)
\]
\[
\hat{x}(0, -\frac{1}{2}) = \frac{1}{\pi} \int_{-1}^{1} p(\tau) x(\tau) d\tau, \quad \hat{x} \left( l, -\frac{1}{2} \right) = \frac{2}{\pi} \int_{-1}^{1} p(\tau) x(\tau) T_l(\tau) d\tau, \quad l \in \mathbb{N}.
\]

In the space \( H^{s+1}_p \) we define a scalar product
\[
\langle f, g \rangle_{H^{s+1}_p} = \sum_{l \in \mathbb{N}_0} l^{2(s+1)} \hat{f} \left( l, -\frac{1}{2} \right) \hat{g} \left( l, -\frac{1}{2} \right), \quad f, g \in H^{s+1}_p.
\]

Being equipped with the above scalar product, the space \( H^{s+1}_p \) becomes a Hilbert one and norm
\[
(2.1)
\]
is expressed via the scalar product
\[
\|x\|_{H^{s+1}_p} = \sqrt{\langle x, x \rangle_{H^{s+1}_p}}, \quad x \in H^{s+1}_p.
\]

We denote by \( H^s_q \) the Sobolev space of order \( s \in \mathbb{R} \) with a weight \( q \), that is, the closure
of the set of polynomials \( \{U_l\}_{l \in \mathbb{N}} \) with respect to the norm
\[
\|y\|_{H^s_q} = \left\{ \sum_{l \in \mathbb{N}} l^{2s} \hat{y}^2 \left( l, \frac{1}{2} \right) \right\}^{1/2}, \quad \hat{y} \left( l, \frac{1}{2} \right) = \frac{2}{\pi} \int_{-1}^{1} q(\tau) y(\tau) U_l(\tau) d\tau, \quad l \in \mathbb{N}.
\]
In the space $H^s_q$ we also define a scalar product
\[ (f,g)_{H^s_q} = \sum_{l \in \mathbb{N}} \int_{-1}^{1} f(l,1/2)\hat{g}(l,1/2), \quad f, g \in H^s_q. \]

Being equipped with the above scalar product, the space $H^s_q$ becomes a Hilbert one, while norm (2.2) is expressed via this scalar product:
\[ \|y\|_{H^s_q} = \sqrt{(y,y)_{H^s_q}}, \quad y \in H^s_q. \]

Hereafter we suppose that the condition $s > 1/2$ holds, under which (see, for instance, [12]) the space $H^s_q$ is embedded into the space of continuous functions, while the space $H^{s+1}_p$ is embedded into the space of the functions having a first continuous derivative.

We denote by $H^{s+1, s+1}_{p,p}$ the space of the functions of two variables, which belong to the space $H^{s+1}_p$ as functions of each variable uniformly in the second variable. For functions $h \in H^{s+1, s+1}_{p,p}$ we define
\[ \hat{h} \left( m, \frac{1}{2}, \tau \right) = \frac{2}{\pi} \int_{-1}^{1} p(t)h(t,\tau)T_m(t)dt, \quad m \in \mathbb{N}_0, \quad t \in (-1, 1), \]
which a $m$th Fourier coefficient of the function $h$ with respect to the first variable, and
\[ \hat{h} \left( t, l, -\frac{1}{2} \right) = \frac{2}{\pi} \int_{-1}^{1} p(\tau)h(t,\tau)T_l(\tau)T_m(t)dt, \quad l \in \mathbb{N}_0, \quad \tau \in (-1, 1), \]
is $l$th Fourier coefficient of the function $h$ with respect to the second variable and
\[ \hat{h} \left( m, \frac{1}{2}, l, -\frac{1}{2} \right) = \frac{4}{\pi^2} \int_{-1}^{1} \int_{-1}^{1} p(t)p(\tau)h(t,\tau)T_l(\tau)T_m(t)d\tau dt, \]
\[ (m,l) \in \mathbb{N}_0^2, \quad (t,\tau) \in (-1, 1)^2, \]
is $(m,l)$th coefficient of the Fourier coefficient of the function $h$ with respect to the both variables. The norm in the space $H^{s+1, s+1}_{p,p}$ is defined by the identity
\[ \|h\|_{H^{s+1, s+1}_{p,p}} = \left\{ \sum_{m \in \mathbb{N}_0} \sum_{l \in \mathbb{N}_0} m^{2(s+1)}l^{2(s+1)} h^2 \left( m, \frac{1}{2}, l, -\frac{1}{2} \right) \right\}^{1/2}, \quad (2.3) \]
while the scalar product is defined by the identity
\[ (f,g)_{H^{s+1, s+1}_{p,p}} = \left\{ \sum_{m \in \mathbb{N}_0} \sum_{l \in \mathbb{N}_0} m^{2(s+1)}l^{2(s+1)} \hat{f} \left( m, \frac{1}{2}, l, -\frac{1}{2} \right) \hat{g} \left( m, \frac{1}{2}, l, -\frac{1}{2} \right) \right\}^{1/2}. \]

Being equipped with the above scalar product, the space $H^{s+1, s+1}_{p,p}$ becomes a Hilbert one, while norm (2.3) is expressed via this scalar product:
\[ \|h\|_{H^{s+1, s+1}_{p,p}} = \sqrt{(h,h)_{H^{s+1, s+1}_{p,p}}}, \quad h \in H^{s+1, s+1}_{p,p}. \]

We fix $n \in \mathbb{N}$ and we denote by
\[ P_n y(t) = \sum_{k=1}^{n} y(t_k) \xi_k(t), \quad t \in (-1, 1), \]
an interpolation Lagrange polynomial of a function \( y \in H^s_q \) over the nodes

\[
t_k = \cos \frac{\pi k}{n + 1}, \quad k = 1, 2, \ldots, n.
\]  

(2.4)

Here

\[
\xi_k(t) = \frac{U_{n+1}(t)}{(t - t_k)U'_{n+1}(t_k)}, \quad k = 1, 2, \ldots, n, \quad t \in (-1, 1),
\]

are fundamental polynomials corresponding to nodes \(2.4\).

We denote by

\[
Q_n y(t) = \sum_{l=1}^{n} \hat{y}_l \left( t, \frac{1}{2} \right) U_l(t), \quad t \in (-1, 1),
\]

a partial sum of Fourier series of a function \( y \in H^s_q \) over the system of polynomials \( \{ U_l \}_{l \in N} \), while \( E_n(y)_q^s \) stands for the best approximation of this functions by the polynomials of order at most \( n - 1 \) in the norm of the space \( H^s_q \). It is known that the best approximation of a function in a Hilbert space is given by a partial sum of its Fourier series and hence,

\[
E_n(y)_q^s = \| y - Q_n y \|_{H^s_q}, \quad y \in H^s_q.
\]

3. Auxiliary results

In this section we provide two lemmata needed in what follows. The proof of the first lemma was given, for instance, in \([13]\), while the proof of the second lemma was provided in \([10]\).

**Lemma 3.1.** Let \( D \) and \( V \) be linear operators acting from a Banach space \( X \) into a Banach space \( Y \). Assume that the operator \( D \) is invertible and the condition \( \| V \|_{X \to Y} \| D^{-1} \|_{Y \to X} < 1 \) is satisfied. Then the operator \( D + V : X \to Y \) is also invertible and the estimate

\[
\|(D + V)^{-1}\|_{Y \to X} \leq \frac{\| D^{-1} \|_{Y \to X}}{1 - \| V \|_{X \to Y} \| D^{-1} \|_{Y \to X}}
\]

holds true.

We again denote by \( X \) and \( Y \) some Banach space and let \( X_n \subset X, Y_n \subset Y, n = 1, 2, \ldots \), be their subspaces. We consider the equations

\[
K x = y, \quad K : X \to Y,
\]

(3.1)

\[
K_n x_n = y_n, \quad K_n : X_n \to Y_n, \quad n = 1, 2, \ldots,
\]

(3.2)

where \( K \) and \( K_n, n = 1, 2, \ldots \), are linear bounded operators.

**Lemma 3.2.** Assume that the operator \( K : X \to Y \) is invertible and the operators \( K_n, n = 1, 2, \ldots \), converge uniformly to \( K \):

\[
\| K - K_n \|_{X_n \to Y} \to 0 \quad \text{as} \quad n \to \infty.
\]

If \( \dim X_n = \dim Y_n, n = 1, 2, \ldots \), then for all \( n \) satisfying the condition

\[
u_n = \| K^{-1} \|_{Y \to X} \| K - K_n \|_{X_n \to Y} < 1,
\]

approximate equations \(3.2\) possess unique solutions \( x^*_n \in X_n \) for arbitrary right hand sides \( y_n \in Y_n \) and the estimate

\[
\| x^* - x^*_n \|_X \leq \frac{\| K^{-1} \|_{Y \to X}}{1 - \nu_n} (\| y - y_n \|_Y + \nu_n \| y \|_Y)
\]

holds, where \( x^* = K^{-1} y \) is the exact solution of equation \(3.1\).
4. Formulation of problem

We consider a singular integro-differential equation

\[ x'(t) + a(t)x(t) + \frac{b(t)}{\pi} \int_{-1}^{1} \frac{p(\tau)x(\tau)d\tau}{\tau - t} + \frac{2}{\pi} \int_{-1}^{1} p(\tau)h(t,\tau)x(\tau)d\tau = y(t), \quad t \in (-1,1), \quad (4.1) \]

with the condition

\[ \int_{-1}^{1} p(\tau)x(\tau)d\tau = 0. \quad (4.2) \]

Here \( x \) is a sought function, while \( a, b, h \) and \( y \) are known functions. We assume that the functions \( a \) and \( b \) belong to the space \( H^{s+1}_p \), the function \( h \) belongs to the space \( H^{s+1}_{p,p} \), \( s \), \( p \), while the function \( y \) belongs to the space \( H^{s}_q \). The singular integral is treated in the sense of Cauchy-Lebesgue principle value.

5. Analysis of solvability

We rewrite problem (4.1), (4.2) as an operator equation:

\[ Kx \equiv Dx + Vx = y, \quad K : X \to Y, \quad (5.1) \]

\[ X = \left\{ x \in H^{s+1}_p \mid \int_{-1}^{1} p(\tau)x(\tau)d\tau = 0 \right\}, \quad Y = H^{s}_q, \]

\[ Dx(t) = x'(t), \quad Vx(t) = Ax(t) + Bx(t) + Ghx(t), \quad t \in (-1,1), \]

\[ Ax(t) = a(t)x(t), \quad Bx(t) = \frac{b(t)}{\pi} \int_{-1}^{1} \frac{p(\tau)x(\tau)d\tau}{\tau - t}, \]

\[ Ghx(t) = \frac{2}{\pi} \int_{-1}^{1} p(\tau)h(t,\tau)x(\tau)d\tau, \quad t \in (-1,1). \]

**Theorem 5.1.** For all \( a, b \in H^{s+1}_p \) and \( h \in H^{s+1,1}_{p,p} \) satisfying the condition

\[ u = C_a \|a\|_{H^{s+1}_p} + C_b \|b\|_{H^{s+1}_p} + C_h \|h\|_{H^{s+1,1}_{p,p}} < 1, \]

\[ C_a = \frac{1}{4} \left( \zeta(4s + 4) + \frac{\pi^2}{6} (1 + 2^{2s+1}) + \frac{\pi^2}{3} 2^2 (2^{2(s+1)}(1 + 3\zeta(2s + 2)) + 7\zeta(2s + 2) + 1) \right), \]

\[ C_b = \frac{\pi^2}{12} (1 + 2^{2s+1})(1 + 3\zeta(2s + 2)), \quad C_h = \frac{\pi^2}{6} (1 + 2^{2s+1}), \quad \zeta(t) = \sum_{j=1}^{\infty} j^{-t}, \]

operator equation (5.1) and hence, problem (4.1), (4.2) are uniquely solvable for arbitrary right hand side \( y \in Y \) and the estimate

\[ \|K^{-1}\|_{Y \to X} \leq (1 - u)^{-1} \]

holds true.

**Proof.** First we are going to prove that the operator \( D : X \to Y \) is invertible and the identities

\[ \|D\|_{X \to Y} = \|D^{-1}\|_{Y \to X} = 1 \]
hold true. Indeed, we take arbitrary $x \in X$ and $y \in Y$ and write them as Fourier series in the corresponding spaces:

$$x(t) = \sum_{l \in \mathbb{N}} \hat{x}(l, -\frac{1}{2}) T_i(t), \quad y(t) = \sum_{l \in \mathbb{N}} y(l, \frac{1}{2}) U_i(t), \quad t \in (-1, 1).$$

In this case the equation

$$Dx = y, \quad D : X \to Y,$$

becomes an infinite system of equations

$$l \hat{x}(l, -\frac{1}{2}) = \hat{y}(l, \frac{1}{2}), \quad l \in \mathbb{N},$$

and its solution is the function

$$x(t) = \sum_{l \in \mathbb{N}} l^{-1} \hat{y}(l, \frac{1}{2}) T_i(t), \quad t \in (-1, 1).$$

An arbitrary choice of the element $y \in Y$ then implies the invertibility of the operator $D : X \to Y$.

Now we are going to calculate the norms of the operators $D : X \to Y$ and $D^{-1} : Y \to X$. For an arbitrary element $x \in X$ we have

$$\|Dx\|_Y^2 = \sum_{l \in \mathbb{N}} l^{2s} \left(\hat{x}(l, -\frac{1}{2})\right)^2 = \sum_{l \in \mathbb{N}} l^{2(s+1)} x^2 \left(l, -\frac{1}{2}\right) = \|x\|_X^2.$$

For an arbitrary element $y \in Y$ we find:

$$\|D^{-1}y\|_X^2 = \sum_{l \in \mathbb{N}} l^{2(s+1)} \left(l^{-1} \hat{y}(l, \frac{1}{2})\right)^2 = \sum_{l \in \mathbb{N}} l^{2s+2} \left(l, \frac{1}{2}\right) = \|y\|_Y^2.$$

This means that $\|D\|_{X \to Y} = \|D^{-1}\|_{Y \to X} = 1$.

Let us estimate the norm of the operator $V : X \to Y$. We again take an arbitrary element $x \in X$

$$x(t) = \sum_{l \in \mathbb{N}} \hat{x}(l, -\frac{1}{2}) T_i(t), \quad t \in (-1, 1),$$

and apply the operator $V$ to this element:

$$Vx = Ax + Bx + Ghx. \quad (5.2)$$

Let us estimate the norm in the space $Y$ of each term in the right hand side of this identity.

For the first term we find that

$$\|Ax\|_Y^2 = \|ax\|_{H_q^2}^2 = \sum_{m \in \mathbb{N}} m^{2s} \hat{x}^2 \left(m, \frac{1}{2}\right)$$

$$= \frac{4}{\pi^2} \sum_{m \in \mathbb{N}} m^{2s} \left(\int_{-1}^{1} q(\tau) \sum_{k \in \mathbb{N}_0} \sum_{l \in \mathbb{N}} \hat{a} \left(k, -\frac{1}{2}\right) \hat{x} \left(l, -\frac{1}{2}\right) T_k(\tau) T_l(\tau) U_m(\tau) d\tau\right)^2$$

$$= \frac{4}{\pi^2} \sum_{m \in \mathbb{N}} m^{2s} \left(\sum_{k \in \mathbb{N}_0} \sum_{l \in \mathbb{N}} \hat{a} \left(k, -\frac{1}{2}\right) \hat{x} \left(l, -\frac{1}{2}\right) \int_{-1}^{1} q(\tau) T_k(\tau) T_l(\tau) U_m(\tau) d\tau\right)^2.$$
Applying twice the Cauchy-Schwartz inequality, we obtain:

\[ \|Ax\|_2^2 \leq \frac{4}{\pi^2} \sum_{m \in \mathbb{N}} m^{2s} \sum_{k \in \mathbb{N}_0} k^{2(s+1)} \sum_{l \in \mathbb{N}} l^{2(s+1)} \left( \frac{1}{2} \right)^2 \left( \frac{1}{2} \right)^2 \]

\[ \cdot \sum_{k \in \mathbb{N}_0} \sum_{l \in \mathbb{N}} k^{-2(s+1)} l^{-2(s+1)} \left( \int_{-1}^{1} q(\tau)T_k(\tau)T_l(\tau)U_m(\tau)d\tau \right)^2 \]

\[ = \frac{4}{\pi^2} \|a\|_{H^{s+1}}^2 \|x\|_{H^{s+1}}^2 \sum_{m \in \mathbb{N}} m^{2s} \sum_{k \in \mathbb{N}_0} \sum_{l \in \mathbb{N}} k^{-2(s+1)} l^{-2(s+1)} \left( \int_{-1}^{1} q(\tau)T_k(\tau)T_l(\tau)U_m(\tau)d\tau \right)^2. \]

The integrals

\[ \int_{-1}^{1} q(\tau)T_k(\tau)T_l(\tau)U_m(\tau)d\tau, \quad k \in \mathbb{N}_0, \quad l, m \in \mathbb{N}, \]

can be found explicitly. Indeed, making the change of the variables \( \tau = \cos \varphi \), we get:

\[ \int_{-1}^{1} q(\tau)T_k(\tau)T_l(\tau)U_m(\tau)d\tau = \int_{0}^{\pi} \cos k\varphi \cos l\varphi \sin m\varphi \sin \varphi d\varphi \]

\[ = \frac{1}{8} \left( \int_{0}^{\pi} \cos(k + l + m - 1)\varphi d\varphi + \int_{0}^{\pi} \cos(k + l - m + 1)\varphi d\varphi \right) \]

\[ + \int_{0}^{\pi} \cos(k - l + m - 1)\varphi d\varphi + \int_{0}^{\pi} \cos(k - l - m + 1)\varphi d\varphi \]

\[ - \int_{0}^{\pi} \cos(k + l + m + 1)\varphi d\varphi - \int_{0}^{\pi} \cos(k + l - m - 1)\varphi d\varphi \]

\[ - \int_{0}^{\pi} \cos(k - l + m + 1)\varphi d\varphi - \int_{0}^{\pi} \cos(k - l - m - 1)\varphi d\varphi \), \]

and this is why

\[ \int_{-1}^{1} q(\tau)T_k(\tau)T_l(\tau)U_m(\tau)d\tau = \frac{\pi}{8} \]

as

\[ m = 2, 3, \ldots, \quad l = 1, 2, \ldots, m - 1, \quad k = m - l - 1; \quad m = 1, \quad l \in \mathbb{N}, \quad k = l; \]

\[ m = 2, 3, \ldots, \quad l = m - 1, m, \ldots, \quad k = l + 1 - m; \]

and

\[ m \in \mathbb{N}, \quad l \in \mathbb{N}, \quad k = m + l - 1; \quad \int_{-1}^{1} q(\tau)T_k(\tau)T_l(\tau)U_m(\tau)d\tau = -\frac{\pi}{8} \]
as
\[ m \in \mathbb{N}, \quad l = 1, 2, \ldots, m + 1, \quad k = m + 1 - l; \]
\[ m \in \mathbb{N}, \quad l = m + 1, m + 2, \ldots, \quad k = l - m - 1; \quad m, l \in \mathbb{N}, \quad k = m + l + 1. \]

For other values of the indices \( k, l \) and \( m \) these integrals vanish. Thus, estimate \([5.3]\) becomes
\[
\|Ax\|_Y^2 \leq \frac{1}{16} \|a\|^2_{H_p^{k+1}} \|x\|^2_{H_p^l} \left( \sum_{m=2}^{\infty} \sum_{l=m-1}^{\infty} m^{2s} l^{-2(s+1)} (m - l - 1)^{-2(s+1)} + \sum_{m=2}^{\infty} \sum_{l=m}^{\infty} m^{2s} l^{-2(s+1)} (m + l - 1)^{-2(s+1)} \right. \\
+ \sum_{m=2}^{\infty} \sum_{l=m-1}^{\infty} m^{2s} l^{-2(s+1)} (m + l - 1)^{-2(s+1)} + \sum_{m=2}^{\infty} \sum_{l=m}^{\infty} m^{2s} l^{-2(s+1)} (m - l - 1)^{-2(s+1)} \\
+ \sum_{m \in \mathbb{N}} \left. \sum_{l \in \mathbb{N}} m^{2s} l^{-2(s+1)} (m - l + 1)^{-2(s+1)} \right)^2.
\]

Let us estimate the expressions under the sum symbols via Hölder inequality and triangle inequality. The first estimate reads as
\[
\|Ax\|_Y^2 \leq \frac{1}{16} \|a\|^2_{H_p^{k+1}} \|x\|^2_{H_p^l} \left( \zeta(4s + 4) + 2^{2(s+1)} \frac{\pi^2}{6} + \sum_{m=2}^{\infty} \sum_{l \in \mathbb{N}} m^{2s} l^{-2(s+1)} (m - l - 1)^{-2(s+1)} \right. \\
+ \sum_{m \in \mathbb{N}} \sum_{l \in \mathbb{N}} m^{2s} l^{-2(s+1)} (m + l - 1)^{-2(s+1)} + \frac{\pi^2}{6} \sum_{m \in \mathbb{N}} \sum_{l \in \mathbb{N}} m^{2s} l^{-2(s+1)} (m - l + 1)^{-2(s+1)} \\
+ \sum_{m \in \mathbb{N}} \left. \sum_{l \in \mathbb{N}} m^{2s} l^{-2(s+1)} (m + l + 1)^{-2(s+1)} \right)^2.
\]
The next estimates are
\[
\sum_{m \in \mathbb{N}} m^{-2} \left( \frac{m}{m+1} \right)^{2(s+1)} \sum_{l \in \mathbb{N}} \frac{(m + 1 - l + 1)^{2(s+1)}}{l^{2(s+1)}(m + 1 - l)^{2(s+1)}} + \sum_{m \in \mathbb{N}} m^{-2} \left( \frac{m}{m+1} \right)^{2(s+1)} \sum_{l \in \mathbb{N}} \frac{(m + l + 1 - l)^{2(s+1)}}{l^{2(s+1)}(m + l + 1)^{2(s+1)}}
\]

The second estimate is of the form
\[
\sum_{m=2}^{\infty} m^{-2} \left( \frac{m}{m-1} \right)^{2(s+1)} \sum_{l \in \mathbb{N}} \frac{(m - l - 1)^{2(s+1)}}{l^{2(s+1)}(m - l - 1)^{2(s+1)}}
\]
\[
\leq 2^{2(s+1)} \sum_{m=2}^{\infty} m^{-2} 2^{2s+1} \left( \sum_{l \in \mathbb{N}} l^{-2(s+1)} + 1 + \sum_{m-1 \neq l \in \mathbb{N}} (m - l - 1)^{-2(s+1)} \right)
\]
\[
\leq 2^{4s+3} \sum_{m=2}^{\infty} m^{-2} (1 + 3\zeta(2s + 2)) \leq 2^{4s+3} \frac{\pi^2}{6} (1 + 3\zeta(2s + 2))
\]
\[
\sum_{m \in \mathbb{N}} m^{-2} \left( \frac{m}{m-1} \right)^{2(s+1)} \sum_{l \in \mathbb{N}} \frac{(m - l + l)^{2(s+1)}}{l^{2(s+1)}(m - l + l)^{2(s+1)}}
\]
\[
\leq 2^{2(s+1)} \pi^2 \frac{1}{6} \zeta(2s + 2).
\]

The next estimates are
\[
\sum_{m \in \mathbb{N}} m^{-2} \left( \frac{m}{m+1} \right)^{2(s+1)} \sum_{l \in \mathbb{N}} \frac{(m + 1 - l + 1)^{2(s+1)}}{l^{2(s+1)}(m + 1 - l)^{2(s+1)}}
\]
\[
\leq 2^{2s+1} \sum_{m \in \mathbb{N}} m^{-2} \left( \sum_{l \in \mathbb{N}} l^{-2(s+1)} + 1 + \sum_{m+1 \neq l \in \mathbb{N}} (m - l + 1)^{-2(s+1)} \right)
\]
\[
\leq 2^{2s+1} \pi^2 \frac{1}{6} (1 + 3\zeta(2s + 2))
\]
and
\[
\sum_{m \in \mathbb{N}} m^{-2} \left( \frac{m}{m+1} \right)^{2(s+1)} \sum_{l \in \mathbb{N}} \frac{(m + l + 1 - l)^{2(s+1)}}{l^{2(s+1)}(m + l + 1)^{2(s+1)}}
\]
\[
\leq 2^{2(s+1)} \sum_{m \in \mathbb{N}} m^{-2} \left( \sum_{l \in \mathbb{N}} l^{-2(s+1)} - \sum_{l \in \mathbb{N}} (m + l + 1)^{-2(s+1)} \right)
\]
\[
\leq 2^{2(s+1)} \pi^2 \frac{1}{6} \zeta(2s + 2).
\]

We finally have:
\[
\|Ax\|_Y \leq C_a \|a\|_{H^{s+1}_p} \|x\|_{H^{s+1}_p},
\]
\[
C_a = \frac{1}{4} \left( \zeta(4s + 4) + \frac{\pi^2}{6}(1 + 2^{2(s+1)}) + \frac{\pi^2}{3} 2^{2s} (2^{2(s+1)}(1 + 3\zeta(2s + 2)) + 7\zeta(2s + 2) + 1) \right).
\]
Since
\[
\frac{1}{\pi} \int_{-1}^{1} \frac{p(\tau)x(\tau)d\tau}{\tau - t} = \sum_{l \in \mathbb{N}} \hat{x} \left( l, -\frac{1}{2} \right) U_l(t), \quad t \in (-1, 1),
\]

JUSTIFICATION OF GALERKIN AND COLLOCATIONS METHODS . . .

99
the square of the norm of the second term in the right hand side of identity (5.2) can be represented as follows:

$$\|Bx\|_Y^2 = \frac{4}{\pi^2} \sum_{m \in \mathbb{N}} m^{2s} \left( \int_{-1}^{1} q(\tau) \sum_{k \in \mathbb{N}_0} \sum_{l \in \mathbb{N}} \hat{b} \left( k, -\frac{1}{2} \right) \hat{x} \left( l, -\frac{1}{2} \right) T_k(\tau) U_l(\tau) U_m(\tau) d\tau \right)^2$$

$$= \frac{4}{\pi^2} \sum_{m \in \mathbb{N}} m^{2s} \left( \sum_{k \in \mathbb{N}_0} \sum_{l \in \mathbb{N}} \hat{b} \left( k, -\frac{1}{2} \right) \hat{x} \left( l, -\frac{1}{2} \right) \int_{-1}^{1} q(\tau) T_k(\tau) U_l(\tau) U_m(\tau) d\tau \right)^2.$$

Again applying twice the Cauchy-Schwartz inequalities to the sums, we find:

$$\|Bx\|_Y^2 \leq \frac{4}{\pi^2} \sum_{m \in \mathbb{N}} m^{2s} \sum_{k \in \mathbb{N}_0} k^{2(s+1)} \hat{b}^2 \left( k, -\frac{1}{2} \right) \sum_{l \in \mathbb{N}} l^{-2(s+1)} \hat{x}^2 \left( l, -\frac{1}{2} \right) \left( \int_{-1}^{1} q(\tau) T_k(\tau) U_l(\tau) U_m(\tau) d\tau \right)^2$$

$$= \frac{4}{\pi^2} \|b\|_{H_p+1}^2 \|x\|_{H_p+1}^2 \sum_{m \in \mathbb{N}} m^{2s} \sum_{k \in \mathbb{N}_0} k^{-2(s+1)} l^{-2(s+1)} \left( \int_{-1}^{1} q(\tau) T_k(\tau) U_l(\tau) U_m(\tau) d\tau \right)^2.$$

The integrals

$$\int_{-1}^{1} q(\tau) T_k(\tau) U_l(\tau) U_m(\tau) d\tau = \int_{0}^{\pi} \cos k \varphi \sin l \varphi \sin m \varphi d\varphi$$

$$= \frac{1}{4} \left( \int_{0}^{\pi} \cos(l - m + k) \varphi d\varphi + \int_{0}^{\pi} \cos(l - m - k) \varphi d\varphi - \int_{0}^{\pi} \cos(l + m + k) \varphi d\varphi + \int_{0}^{\pi} \cos(l + m - k) \varphi d\varphi \right),$$

$$k \in \mathbb{N}_0, \ l, m \in \mathbb{N},$$

can be found explicitly:

$$\int_{0}^{\pi} \cos(k - m + l) \varphi d\varphi = \pi, \ m \in \mathbb{N}, \ l = 1, 2, \ldots, m, \ k = m - l;$$

$$\int_{0}^{\pi} \cos(-k - m + l) \varphi d\varphi = \pi, \ m \in \mathbb{N}, \ l = m, m + 1, \ldots, \ k = l - m;$$

$$\int_{0}^{\pi} \cos(-k + m + l) \varphi d\varphi = \pi \ m, l \in \mathbb{N}, \ k = m + l;$$
and vanish for other values of the indices $k$, $l$ and $m$. This is why estimate (5.4) becomes:

$$
\|Bx\|_{Y}^{2} \leq \frac{1}{4} \|b\|_{H^{p+1}}^{2} \|x\|_{H^{p+1}}^{2} \left( \sum_{m \in \mathbb{N}} \sum_{l=1}^{m} m^{2s} (m-l)^{-2(s+1)} l^{-2(s+1)} \right)^{2}
$$

$$
\left( \sum_{m \in \mathbb{N}} \sum_{l=1}^{m} m^{2s} (m-l)^{-2(s+1)} l^{-2(s+1)} \right)^{2} + \sum_{m \in \mathbb{N}} m^{2s} \sum_{l=1}^{m} (m-l)^{-2(s+1)} l^{-2(s+1)} \sum_{l \in \mathbb{N}} (m+l)^{-2(s+1)} l^{-2(s+1)} \right)^{2}
$$

$$
\leq \frac{1}{4} \|b\|_{H^{p+1}}^{2} \|x\|_{H^{p+1}}^{2} \left( \frac{\pi^{2}}{6} + 2^{s+1} \sum_{m \in \mathbb{N}} m^{-2} \sum_{l \in \mathbb{N}} (m-l)^{2(s+1)} l^{2(s+1)} \right)^{2}
$$

$$
\leq \frac{1}{4} \|b\|_{H^{p+1}}^{2} \|x\|_{H^{p+1}}^{2} \left( \frac{\pi^{2}}{6} + 2^{s+1} \sum_{m \in \mathbb{N}} m^{-2} \left( \sum_{l \in \mathbb{N}} l^{-2(s+1)} + \sum_{l \in \mathbb{N}} (m-l)^{-2(s+1)} \right) \right)^{2}
$$

$$
\leq \frac{1}{4} \|b\|_{H^{p+1}}^{2} \|x\|_{H^{p+1}}^{2} \left( \frac{\pi^{2}}{6} + 2^{s+1} \sum_{m \in \mathbb{N}} m^{-2} \left( \sum_{l \in \mathbb{N}} l^{-2(s+1)} - \sum_{l \in \mathbb{N}} (m+l)^{-2(s+1)} \right) \right)^{2}
$$

$$
\leq \frac{1}{4} \|b\|_{H^{p+1}}^{2} \|x\|_{H^{p+1}}^{2} \left( \frac{\pi^{2}}{6} + 2^{s+1} \frac{\pi^{2}}{6} (1 + 3\zeta(2s + 2)) + \frac{\pi^{2}}{6} \zeta(2s + 2) \right)^{2}
$$

$$
\leq \frac{1}{4} \|b\|_{H^{p+1}}^{2} \|x\|_{H^{p+1}}^{2} \left( \frac{\pi^{2}}{6} (1 + 2^{s+1})(1 + 3\zeta(2s + 2)) \right)^{2}
$$

A final estimate for the second term in the right hand side of identity (5.2) reads as

$$
\|Bx\|_{Y} \leq C_{b} \|b\|_{H^{p+1}} \|x\|_{H^{p+1}}, \quad C_{b} = \frac{\pi^{2}}{12} (1 + 2^{s+1})(1 + 3\zeta(2s + 2)).
$$

In order to estimate the norm of the third term in the right hand side of identity (5.2) we observe that the expansion

$$
h(t, \tau) = \sum_{k \in \mathbb{N}_{0}} \hat{h} \left( t, k, -\frac{1}{2} \right) T_{k}(\tau), \quad (t, \tau) \in (-1, 1)^{2},
$$

allows us to represent $Gh x$ as

$$
Gh x(t) = \sum_{l \in \mathbb{N}} \hat{h}(t, l, -\frac{1}{2}) \hat{x} \left( l, -\frac{1}{2} \right), \quad t \in (-1, 1).
$$

Now the square of the norm of the third term can be estimated as

$$
\|Gh x\|_{Y}^{2} = \frac{4}{\pi^{2}} \sum_{m \in \mathbb{N}} m^{2s} \left( \int_{-1}^{1} q(\tau) \sum_{l \in \mathbb{N}} \hat{h} \left( \tau, l, -\frac{1}{2} \right) \hat{x} \left( l, -\frac{1}{2} \right) U_{m}(\tau) d\tau \right)^{2}
$$
The integrals
\[ \int_{-1}^{1} q(\tau) T_k(\tau) U_m(\tau) d\tau, \quad k \in \mathbb{N}_0, \quad m \in \mathbb{N}, \]
are equal to \( \frac{\pi}{4} \) for \( m = 1, k = 0 \) and for \( m \in \mathbb{N}, k = m - 1 \) and they are equal to \(-\frac{\pi}{4}\) for \( m \in \mathbb{N}, k = m + 1 \). For other values of the indices they vanish and hence,

\[
\|Ghx\|_Y^2 \leq \frac{1}{4} \|x\|^2_{H^{p+1}} \|h\|^2_{H^{p+1}, s+1} \left( 1 + \sum_{m \in \mathbb{N}} m^2 (m-1)^{-2(s+1)} + \sum_{m \in \mathbb{N}} m^2 (m+1)^{-2(s+1)} \right)^2 \\
\leq \frac{1}{4} \|x\|^2_{H^{p+1}} \|h\|^2_{H^{p+1}, s+1} \left( 1 + \sum_{m \in \mathbb{N}} m^{-2} \left( \frac{m}{m-1} \right)^{2(s+1)} + \sum_{m \in \mathbb{N}} m^{-2} \left( \frac{m}{m+1} \right)^{2(s+1)} \right)^2 \\
\leq \frac{1}{4} \|x\|^2_{H^{p+1}} \|h\|^2_{H^{p+1}, s+1} \left( 1 + \frac{\pi^2}{6} 2^{2s+1} + \frac{\pi^2}{6} \right)^2 \\
\leq \frac{1}{4} \|x\|^2_{H^{p+1}} \|h\|^2_{H^{p+1}, s+1} \left( \frac{\pi^2}{3} (1 + 2^{2s+1}) \right)^2,
\]

that is,

\[
\|Ghx\|_Y \leq C_h \|x\|_{H^{p+1}} \|h\|_{H^{p+1}, s+1}, \quad C_h = \frac{\pi^2}{6} (1 + 2^{2s+1}).
\]

Collecting the obtained estimates, we find that

\[
\|V\|_{X \to Y} \leq \|a\|_{H^{p+1}} + \|b\|_{H^{p+1}} + C_h \|h\|_{H^{p+1}, s+1},
\]

and by Lemma 3.1 for all \( a, b \) and \( h \) such that

\[
u = C_a \|a\|_{H^{p+1}} + C_b \|b\|_{H^{p+1}} + C_h \|h\|_{H^{p+1}, s+1} < 1,
\]

the operator

\[
K = D + V, \quad K : X \to Y,
\]

is invertible and the inverse operator \( K^{-1} \) is bounded:

\[
\|K^{-1}\|_{Y \to X} \leq (1 - \nu)^{-1}.
\]

The proof is complete. \( \square \)

The conditions ensuring the invertibility of the operator \( K : X \to Y \) provided in Theorem 5.1 are only sufficient. Indeed, the class of problems (4.1), (4.2) with invertible operators is much wider. Nevertheless, Theorem 5.1 is needed to be sure that the assumption on the invertibility of the operators in Theorem 6.1 in the next section to be non-empty.
6. Galerkin method

We fix $n \in \mathbb{N}$ and we seek an approximate solution to problem (4.1), (4.2) as a polynomial

$$x_n(t) = \sum_{l=1}^{n} \hat{x}(l, -\frac{1}{2}) T_l(t), \quad t \in (-1, 1).$$

We find the unknown coefficients $\{\hat{x}(l, -\frac{1}{2})\}_{l=1}^{n}$ via the system of linear equations in the Galerkin method:

$$\langle K x_n, U_m \rangle_{H^{q}_q} = \langle y, U_m \rangle_{H^{q}_q}, \quad m = 1, 2, \ldots, n. \quad (6.1)$$

**Theorem 6.1.** Assume that the operator $K : X \rightarrow Y$ in problem (4.1), (4.2) is invertible and the inverse operator $K^{-1}$ is bounded. Then for all $n \in \mathbb{N}$ such that

$$u_n = \|K^{-1}\|_{Y \rightarrow X} \left( \frac{1}{4} \|a\|_{H^{p+1}_p} (2^{2(s+1)} + (2^{2(s+1)} + 1)^2 \zeta(2s + 2)) \right. \right.$$

$$+ \frac{1}{2} \|b\|_{H^{p+1}_p} (2^{2(s+1)} + 1) \zeta(2s + 2) + \frac{1}{2} \|b\|_{H^{p+1}_p} 2^{2(s+1)} \right) n^{-1} < 1$$

system of equations (6.1) possesses a unique solution $\{\hat{x}(l, -\frac{1}{2})\}_{l=1}^{n}$, and approximate solutions

$$x^*_n(t) = \sum_{l=1}^{n} \hat{x}(l, -\frac{1}{2}) T_l(t), \quad t \in (-1, 1),$$

converge to the exact solution $x^* = K^{-1}y$ of problem (4.1), (4.2) in the norm of the space $X$ with the rate

$$\|x^* - x^*_n\|_X \leq \frac{\|K^{-1}\|_{Y \rightarrow X}}{1 - u_n} (E_n(y)_q + u_n \|y\|_Y).$$

**Proof.** We fix $n \in \mathbb{N}$ and by $X_n = \text{span}\{T_i\}_{i=1}^{n}$ we denote a subspace of the space $X$ of dimension $n$, while $Y_n = \text{span}\{U_l\}_{l=1}^{n}$ is a subspace of space $Y$ of dimension $n$. Now we can write system of equations (6.1) in an operator form as

$$K_n x_n = y_n, \quad K_n : X_n \rightarrow Y_n, \quad K_n = Q_n K, \quad y_n = Q_n y.$$

Let us estimate how close the operators $K$ and $K_n$ are on $X_n$. In order to do this, we take an arbitrary element $x_n \in X_n$ and estimate the difference $K x_n - K_n x_n$ in the norm of the space $Y$

$$\|K x_n - K_n x_n\|_Y = \|K x_n - Q_n K x_n\|_Y \leq \|Ax_n - Q_n Ax_n\|_Y + \|Bx_n - Q_n Bx_n\|_Y + \|G h x_n - Q_n G h x_n\|_Y. \quad (6.2)$$

For the first term in the right hand side in (6.2) we get:

$$\|Ax_n - Q_n Ax_n\|_Y^2 = \sum_{m=n+1}^{\infty} m^{2s} \tilde{a}(x_n, m, \frac{1}{2})^2$$

$$= \frac{4}{\pi^2} \sum_{m=n+1}^{\infty} m^{2s} \int_{-1}^{1} \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} \tilde{a} \left( k, -\frac{1}{2} \right) \tilde{x}_n \left( l, -\frac{1}{2} \right) T_k(\tau) T_l(\tau) U_m(\tau) d\tau$$

$$= \frac{4}{\pi^2} \sum_{m=n+1}^{\infty} m^{2s} \left( \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} \tilde{a} \left( k, -\frac{1}{2} \right) \tilde{x}_n \left( l, -\frac{1}{2} \right) \right)^2 \left( \int_{-1}^{1} q(\tau) T_k(\tau) T_l(\tau) U_m(\tau) d\tau \right)^2.$$ 

Applying twice the Cauchy-Schwartz inequality to the sums as in the proof of Theorem 5.1 we get

$$\|Ax_n - Q_n Ax_n\|_Y^2 \leq \frac{4}{\pi^2} \|a\|_{H^{p+1}_p}^2 \|x_n\|_{H^{p+1}_p}^2. \quad (6.3)$$
The integrals
\[
\int_{-1}^{1} q(\tau) T_k(\tau) T_l(\tau) U_m(\tau) d\tau, \quad k \in \mathbb{N}_0, \quad l = 1, 2, \ldots, n, \quad m = n + 1, n + 2, \ldots,
\]
have been calculated in the proof of Theorem 5.1. They are equal to \( \frac{\pi}{8} \) as
\[
m = n + 1, n + 2, \ldots, \quad l = 1, 2, \ldots, n, \quad k = m - l - 1;
\]
\[
m = n + 1, \quad l = n, \quad k = 0;
\]
\[
m = n + 1, n + 2, \ldots, \quad l = 1, 2, \ldots, n, \quad k = m + l - 1;
\]
and to \( -\frac{\pi}{8} \) as
\[
m = n + 1, n + 2, \ldots, \quad l = 1, 2, \ldots, n, \quad k = m - l + 1;
\]
\[
m = n + 1, n + 2, \ldots, \quad l = 1, 2, \ldots, n, \quad k = m + l + 1.
\]
For other values of the indices \( k, l \) and \( m \) these integrals vanish. Thus, estimate (6.3) becomes
\[
\|Ax_n - Q_n Ax_n\|_Y^2 \leq \frac{1}{16} \|a\|_{H_{p+1}}^2 \|x_n\|_{H_{p+1}}^2
\]
\[
\cdot \sum_{m=n+1}^{\infty} \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} m^{2s} l^{-2(s+1)} (m - l - 1)^{-2(s+1)} \left( \int_{-1}^{1} q(\tau) T_k(\tau) T_l(\tau) U_m(\tau) d\tau \right)^2.
\]
Twice applying Cauchy-Schwartz inequality to the sums, we find:

\[ + 2^{4s+3} \sum_{m=n+1}^{\infty} m^{-2} \left( \sum_{l=1}^{n} l^{-2(s+1)} + \sum_{l=1}^{n} (m-l-1)^{-2(s+1)} \right) \]

\[ + 2^{2(s+1)} \sum_{m=n+1}^{\infty} m^{-2} \left( \sum_{l=1}^{n} l^{-2(s+1)} - \sum_{l=1}^{n} (m+l-1)^{-2(s+1)} \right) \]

\[ + 2^{2(s+1)} \sum_{m=n+1}^{\infty} m^{-2} \left( \sum_{l=1}^{n} l^{-2(s+1)} + \sum_{l=1}^{n} (m-l+1)^{-2(s+1)} \right) \]

\[ + \sum_{m=n+1}^{\infty} m^{-2} \left( \sum_{l=1}^{n} l^{-2(s+1)} - \sum_{l=1}^{n} (m+l-1)^{-2(s+1)} \right)^2 \]

\[ \leq \frac{1}{16} \| a \|_{H^{s+1}_p}^2 \| x_n \|_{H^{s+1}_p}^2 \left( 2^{2(s+1)}(n+1)^{-2} + 2^{4(s+1)} \zeta(2s+2) \sum_{m=n+1}^{\infty} m^{-2} \right) \]

\[ + 2^{s+1} \zeta(2s+2) \sum_{m=n+1}^{\infty} m^{-2} + \zeta(2s+2) \sum_{m=n+1}^{\infty} m^{-2} \right)^2 \]

\[ \leq \frac{1}{16} \| a \|_{H^{s+1}_p}^2 \| x_n \|_{H^{s+1}_p}^2 \left( 2^{2(s+1)} + (2^{2(s+1)} + 1)^2 \zeta(2s+2) \right)^2 n^{-2}. \]

Finally we have

\[ \| Ax_n - Q_n Ax_n \|_Y \leq \frac{1}{4} \| a \|_{H^{s+1}_p} \| x \|_{H^{s+1}_p} \left( 2^{2(s+1)} + (2^{2(s+1)} + 1)^2 \zeta(2s+2) \right) n^{-1}. \]

We represent the square of the norm of the second term in the right hand side of identity (6.2) as follows:

\[ \| Bx_n - Q_n Bx_n \|_Y^2 = \frac{4}{\pi^2} \sum_{m=n+1}^{\infty} m^{2s} \left( \int_{-1}^{1} \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} \hat{b} \left( k, -\frac{1}{2} \right) \tilde{x}_n \left( l, -\frac{1}{2} \right) T_k(\tau) U_l(\tau) U_m(\tau) d\tau \right)^2 \]

\[ = \frac{4}{\pi^2} \sum_{m=n+1}^{\infty} m^{2s} \left( \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} \hat{b} \left( k, -\frac{1}{2} \right) \tilde{x}_n \left( l, -\frac{1}{2} \right) \int_{-1}^{1} q(\tau) T_k(\tau) U_l(\tau) U_m(\tau) d\tau \right)^2. \]

Twice applying Cauchy-Schwartz inequality to the sums, we find:

\[ \| Bx_n - Q_n Bx_n \|_Y^2 \leq \frac{4}{\pi^2} \sum_{m=n+1}^{\infty} m^{2s} \sum_{k \in \mathbb{N}_0} \hat{b}^2 \left( k, -\frac{1}{2} \right) \]

\[ \cdot \sum_{l=1}^{n} l^{2(s+1)} \tilde{x}_n^2 \left( l, -\frac{1}{2} \right) \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} k^{-2(s+1)} l^{-2(s+1)} \]

\[ \cdot \left( \int_{-1}^{1} q(\tau) T_k(\tau) U_l(\tau) U_m(\tau) d\tau \right)^2 \]

\[ = \frac{4}{\pi^2} \| b \|_{H^{s+1}_p}^2 \| x_n \|_{H^{s+1}_p}^2 \sum_{m=n+1}^{\infty} m^{2s} \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} k^{-2(s+1)} l^{-2(s+1)} \]

\[ \cdot \left( \int_{-1}^{1} q(\tau) T_k(\tau) U_l(\tau) U_m(\tau) d\tau \right)^2. \]
The integrals
\[
\int_{-1}^{1} q(\tau) T_k(\tau) U_l(\tau) U_m(\tau) d\tau, \quad k \in \mathbb{N}_0, \quad l = 1, 2, \ldots, n, \quad m = n + 1, n + 2, \ldots,
\]
have been also calculated in the proof of Theorem 5.1. The are equal to \( \frac{\pi}{4} \) as
\[
m = n + 1, n + 2, \ldots, \quad l = 1, 2, \ldots, n, \quad k = m - l;
\]
and to \(-\frac{\pi}{4}\) as
\[
m = n + 1, n + 2, \ldots, \quad l = 1, 2, \ldots, n, \quad k = m + l.
\]
For other values of the indices \( k, l \) and \( m \) these integrals vanish. Thus, estimate (6.4) becomes
\[
\|Bx_n - Q_n Bx_n\|_Y^2 \leq \frac{1}{4} \|b\|_H^{2+1} \|x_n\|_H^{2+1} \left( \sum_{m=n+1}^{\infty} m^{2} \sum_{l=1}^{n} l^{2(s+1)} (m - l)^{-2(s+1)} \right)
\]
\[
+ \sum_{m=n+1}^{\infty} m^{2} \sum_{l=1}^{n} l^{-2(s+1)} (m + l)^{-2(s+1)} \left( m^{2(s+1)} \right)^2
\]
\[
\leq \frac{1}{4} \|b\|_H^{2+1} \|x_n\|_H^{2+1} \left( \sum_{m=n+1}^{\infty} m^{-2} \sum_{l=1}^{n} l^{2(s+1)} (m + l)^{2(s+1)} \right)
\]
\[
+ \sum_{m=n+1}^{\infty} m^{-2} \sum_{l=1}^{n} (m - l)^{-2(s+1)} \left( m^{2(s+1)} \right)^2
\]
\[
\leq \frac{1}{4} \|b\|_H^{2+1} \|x_n\|_H^{2+1} \left( 2^{2s+1} \sum_{m=n+1}^{\infty} m^{-2} \left( \sum_{l=1}^{n} l^{-2(s+1)} + \sum_{l=1}^{n} (m + l)^{-2(s+1)} \right) \right)^2
\]
\[
\leq \frac{1}{4} \|b\|_H^{2+1} \|x_n\|_H^{2+1} \left( 2^{2(s+1)}(2^{2(s+1)}n^{-1}\zeta(2s + 2) + n^{-1}\zeta(2s + 2))^2 \right)
\]
\[
= \frac{1}{4} \|b\|_H^{2+1} \|x_n\|_H^{2+1} \left( 2^{2(s+1)} + 1 \right)^2 n^{-2}\zeta(2s + 2).
\]

We finally obtain:
\[
\|Bx_n - Q_n Bx_n\|_Y \leq \frac{1}{2} \|b\|_H^{2+1} \|x_n\|_H^{2+1} (2^{2(s+1)} + 1) \zeta(2s + 2)n^{-1}.
\]

In order to estimate the third term in the right hand side of (6.2) we note that the expansion
\[
h(t, \tau) = \sum_{k \in \mathbb{N}_0} \hat{h} \left( t, -k, -\frac{1}{2} \right) T_k(\tau), \quad (t, \tau) \in (-1, 1)^2,
\]
allows us to represent the function \( G h x_n \) as a double series
\[
G h x_n(t) = \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} \hat{h} \left( k, -\frac{1}{2}, l, -\frac{1}{2} \right) \hat{x}_n \left( l, -\frac{1}{2} \right) T_k(t), \quad t \in (-1, 1).
\]

Now the square of the norm of the third term in the right hand side of (6.2) can be estimated as
\[
\|G h x_n - Q_n G h x_n\|_Y^2 = \sum_{m=n+1}^{\infty} m^{2} \|G h x_n\|^2 (m, \frac{1}{2})
\]
Collecting the obtained estimates, we find:

\[
\frac{4}{\pi^2} \sum_{m=n+1}^{\infty} m^{2s} \left( \int_{-1}^{1} q(\tau) \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} \hat{h}(k, -\frac{1}{2}, l, -\frac{1}{2}) \tilde{x}_n(l, -\frac{1}{2}) T_k(\tau) U_m(\tau) d\tau \right)^2 \\
\leq \frac{4}{\pi^2} \sum_{m=n+1}^{\infty} m^{2s} \sum_{k \in \mathbb{N}_0} \sum_{l=1}^{n} l^{2(s+1)} \tilde{x}_n(l, -\frac{1}{2}) \sum_{l=1}^{n} l^{-2(s+1)} \sum_{k \in \mathbb{N}_0} k^{2(s+1)} \tilde{\gamma}^2(k, -\frac{1}{2}, l, -\frac{1}{2}) \\
\cdot \sum_{k \in \mathbb{N}_0} k^{-2(s+1)} \left( \int_{-1}^{1} q(\tau) T_k(\tau) U_m(\tau) d\tau \right)^2 \\
\leq \frac{4}{\pi^2} \|x_n\|_{H_{p+1}^0}^2 \|h\|_{H_{p+1}^0}^2 \sum_{m=n+1}^{\infty} \sum_{k \in \mathbb{N}_0} m^{2s} k^{-2(s+1)} \left( \int_{-1}^{1} q(\tau) T_k(\tau) U_m(\tau) d\tau \right)^2.
\]

The integrals

\[
\int_{-1}^{1} q(\tau) T_k(\tau) U_m(\tau) d\tau, \ k \in \mathbb{N}_0, \ m = n + 1, n + 2, \ldots,
\]

have been calculated in the proof of Theorem 5.1. They are equal to \( \frac{n}{2} \) as \( m = n + 1, n + 2, \ldots, k = m - 1 \), and to \( -\frac{n}{2} \) as \( m = n + 1, n + 2, \ldots, k = m + 1 \). For other values of the indices \( k \) and \( m \) they vanish. This is why

\[
\|Gh x_n - Q_n Gh x_n\|_Y^2 \leq \frac{1}{4} \|x_n\|_{H_{p+1}^0}^2 \|h\|_{H_{p+1}^0}^2 \left( \sum_{m=n+1}^{\infty} m^{2s} (m - 1)^{-2(s+1)} \right) \\
+ \sum_{m=n+1}^{\infty} m^{2s} (m + 1)^{-2(s+1)} \left( \sum_{m=n+1}^{\infty} m^{-2} \left( \frac{m}{m - 1} \right)^{2(s+1)} \right) \\
\leq \frac{1}{4} \|x_n\|_{H_{p+1}^0}^2 \|h\|_{H_{p+1}^0}^2 \left( \sum_{m=n+1}^{\infty} m^{-2} \left( \frac{m}{m + 1} \right)^{2(s+1)} \right) \\
+ \sum_{m=n+1}^{\infty} m^{-2} \left( \frac{m}{m + 1} \right)^{2(s+1)} \left( 2^{2(s+1)} + 1 \right)^2 n^{-2}.
\]

We finally have:

\[
\|Gh x_n - Q_n Gh x_n\|_Y \leq \frac{1}{2} \|h\|_{H_{p+1}^0} \|x_n\|_{H_{p+1}^0} (2^{2(s+1)} + 1) n^{-1}.
\]

Collecting the obtained estimates, we find:

\[
\|K x_n - K_n x_n\|_Y \leq \left( \frac{1}{4} \|a\|_{H_{p+1}^0} (2^{2(s+1)} + 1)^2 \zeta(2s + 2) \right) \\
+ \frac{1}{2} \|b\|_{H_{p+1}^0} (2^{2(s+1)} + 1) \zeta(2s + 2) + \frac{1}{2} \|h\|_{H_{p+1}^0} \|x_n\| \cdot n^{-1} \|x_n\|_X.
\]
This means that as \( n \to \infty \), the operators \( K_n \) converge uniformly to the operator \( K \) with the estimate

\[
\| K - K_n \|_{X \to Y} \leq \left( \frac{1}{4} \| a \|_{H^{s+1}_p} (2^{2(s+1)} + (2^{2(s+1)} + 1)^2 \zeta (2s + 2)) + \frac{1}{2} \| b \|_{H^{s+1}_p} (2^{2(s+1)} + 1) \zeta (2s + 2) + \frac{1}{2} \| h \|_{H^{s+1}_p} (2^{2(s+1)}) \right)^{-1}.
\]

By Lemma 3.2, for all \( n \) such that

\[
| u_n - \| K^{-1} \|_{Y \to X} \left( \frac{1}{4} \| a \|_{H^{s+1}_p} (2^{2(s+1)} + (2^{2(s+1)} + 1)^2 \zeta (2s + 2)) + \frac{1}{2} \| b \|_{H^{s+1}_p} (2^{2(s+1)} + 1) \zeta (2s + 2) + \frac{1}{2} \| h \|_{H^{s+1}_p} (2^{2(s+1)}) \right)| < 1
\]

system of equations (6.1) possesses a unique solution \( \{ \hat{x}_n^*(l, -\frac{1}{2}) \}_{l=1}^n \) for each right hand side \( y_n \in Y_n \) and the approximate solutions

\[
x_n^*(t) = \sum_{l=1}^n \hat{x}_n^* \left( l, -\frac{1}{2} \right) T_l(t), \quad t \in (-1, 1),
\]

converge to the exact solution \( X^* \) of problem (4.1), (4.2) with the estimate

\[
\| x^* - x_n^* \|_X \leq \frac{\| K^{-1} \|_{Y \to X} (E_n(y)_q^* + u_n \| g \|_Y)}{1 - u_n}.
\]

The proof is complete. \( \square \)

### 7. Collocation Method

We again fix \( n \in \mathbb{N} \). As in the Galerkin method, we seek an approximate solution to problem (4.1), (4.2) as a partial sum of the Fourier series

\[
x_n(t) = \sum_{l=1}^n \hat{x}_n \left( l, -\frac{1}{2} \right) T_l(t), \quad t \in (-1, 1),
\]

but now its coefficients \( \{ \hat{x}_n \left( l, -\frac{1}{2} \right) \}_{l=1}^n \) are sought by the collocation method via the system of equations

\[
K x_n(t_k) = y(t_k), \quad k = 1, 2, \ldots, n,
\]

over nodes (2.4).

Denoting \( w = K x_n - y \), we can write the Galerkin method as the system of equations

\[
\frac{2}{\pi} \int_{-1}^1 q(\tau) w(\tau) U_l(\tau) d\tau = 0, \quad l = 1, 2, \ldots, n, \tag{7.1}
\]

while the collocation method is written as the system of equations

\[
w(t_k) = 0, \quad k = 1, 2, \ldots, n. \tag{7.2}
\]

We approximate integrals (7.1) by interpolating quadrature sums

\[
\frac{2}{\pi} \int_{-1}^1 q(\tau) P_n w(\tau) U_l(\tau) d\tau = \frac{2}{n + 1} \sum_{k=1}^n w(t_k) U_l(t_k) \sin^2 \frac{\pi k}{n + 1}, \quad l = 1, 2, \ldots, n,
\]
and we denote by
\[ r_l = 2 \pi \int_{-1}^{1} q(\tau) w_1(\tau) d\tau - \frac{2}{n+1} \sum_{k=1}^{n} w(t_k) U_l(t_k) \sin^2 \frac{\pi k}{n+1}, \quad l = 1, 2, \ldots, n, \]
the error terms of these quadrature sums. We form a polynomial
\[ R_n w(t) = \sum_{l=1}^{n} r_l U_l(t), \quad t \in (-1, 1), \]
by the numbers \( \{r_l\}_{l=1}^{n} \). Now we write the system of equations for the Galerkin method for the function \( w - R_n w \)
\[
\frac{2}{\pi} \int_{-1}^{1} q(\tau)(w - R_n w)(\tau) U_l(\tau) d\tau = 0, \quad l = 1, 2, \ldots, n. \quad (7.3)
\]
We call system of equations (7.3) a modified Galerkin method for problem (4.1), (4.2).

**Lemma 7.1.** Collocation method (7.2) and modified Galerkin method (7.3) are equivalent in the sense that identities (7.2) hold if and only if identities (7.3) hold.

**Proof.** We represent identities (7.3) as
\[
\frac{2}{\pi} \int_{-1}^{1} q(\tau)(w - R_n w)(\tau) U_l(\tau) d\tau = \frac{2}{n+1} \sum_{k=1}^{n} w(t_k) U_l(t_k) \sin^2 \frac{\pi k}{n+1}, \quad l = 1, 2, \ldots, n.
\]
Now identities (7.3) are trivially implied by identities (7.2).

Suppose that identities (7.3) hold. The polynomials \( U_l, l = 0, 1, \ldots, n \), are linearly independent. Each of them is uniquely determined by its values at the points \( t_k, k = 0, 1, \ldots, n \), and this is why the vectors \( U_l(t_k), k = 0, 1, \ldots, n, l = 0, 1, \ldots, n \), form a linearly independent system of vectors. This implies that the matrix \( (U_l(t_k))_{l,k=1}^{n} \) is non-degenerate and this is why a homogeneous system of equations
\[
\sum_{k=1}^{n} w(t_k) U_l(t_k) \sin^2 \frac{\pi k}{n+1} = 0, \quad l = 1, 2, \ldots, n,
\]
has only the zero solution
\[ w(t_k) \sin^2 \frac{\pi k}{n+1} = 0, \quad k = 1, 2, \ldots, n. \]
Since
\[ \sin^2 \frac{\pi k}{n+1} \neq 0, \quad k = 1, 2, \ldots, n, \]
then
\[ w(t_k) = 0, \quad k = 1, 2, \ldots, n. \]
The proof is complete.

**Theorem 7.1.** Let the inverse operator \( K : X \rightarrow Y \) of problem (4.1), (4.2) be invertible and the inverse operator be bounded. Then for all \( n \in \mathbb{N} \) such that
\[
u_n = \frac{\|K\|_{X \rightarrow Y} \|K^{-1}\|_{Y \rightarrow X}}{1 - \nu_n} < \frac{1}{2},
\]
the system of equations of the collocation method \((7.2)\) has a unique solution \(\{\hat{x}_n^*(l, -\frac{1}{2})\}_{l=1}^n\) and the approximate solutions

\[
x_n^*(t) = \sum_{l=1}^n \hat{x}_n^*(l, -\frac{1}{2}) T_l(t), \quad t \in (-1, 1),
\]

converge to the exact solution \(x^*\) of problem \((4.1), (4.2)\) with the rate

\[
\|x^* - x_n^*\|_X \leq \frac{2\|K^{-1}\|_{Y \rightarrow X} (E_n(y)_{\hat{q}}^* + u_n\|y\|_Y)}{1 - u_n},
\]

Proof. Following Lemma 7.1, we write the system of equations of collocation method \((7.2)\) as system of equations \((7.3)\) of a modified Galerkin method. Then, in operator form system of equations \((7.3)\) reads as \(Q_n w = Q_n R_n w\). Making the inverse change \(w = K x_n - y\), we obtain the equation

\[
Q_n K x_n = Q_n(y + R_n w)
\]

of the Galerkin method for equation

\[
K x = y + R_n w.
\]

By Theorem 6.1, the operator \(K_n = Q_n K\) is invertible in the pair of spaces \((X_n, Y_n)\) and the error of the approximate solution \(x_n^*\) of equation \((7.4)\) in the Galerkin method, and hence, of problem \((4.1), (4.2)\) in the collocation method is estimated by the inequality

\[
\|x^* - x_n^*\|_X \leq \frac{\|K^{-1}\|_{Y \rightarrow X} (E_n(y + R_n w)_{\hat{q}}^* + u_n\|y + R_n w\|_Y)}{1 - u_n}, \quad w = K x_n^* - y. \tag{7.5}
\]

Since \(R_n w\) is a polynomial of degree at most \(n - 1\), then \(E(y + R_n w)_{\hat{q}}^* = E_n(y)_{\hat{q}}^*\). The coefficients \(r_l, l = 1, 2, \ldots, n\), are the first \(n\) Fourier coefficients of the function \(w - P_n w\) and this is why \(R_n w = Q_n (w - P_n w)\). But \(P_n w = 0\) and hence \(R_n w = Q_n w\). Now estimate \((7.5)\) can be written as

\[
\|x^* - x_n^*\|_X \leq \frac{\|K^{-1}\|_{Y \rightarrow X} (E_n(y)_{\hat{q}}^* + u_n\|y\|_Y)}{1 - u_n} + \frac{\|K^{-1}\|_{Y \rightarrow X} u_n\|Q_n (K x_n^* - y)\|_Y}{1 - u_n}
\]

\[
\leq \frac{\|K^{-1}\|_{Y \rightarrow X} (E_n(y)_{\hat{q}}^* + u_n\|y\|_Y)}{1 - u_n} + \frac{\|K^{-1}\|_{Y \rightarrow X} u_n\|K\|_{X \rightarrow Y} \|x_n^* - x^*\|_X}{1 - u_n}.
\]

For all \(n\) such that

\[
u_n = \frac{\|K^{-1}\|_{Y \rightarrow X} \|K\|_{X \rightarrow X}}{1 - u_n} < \frac{1}{2},
\]

we obtain the estimate

\[
\frac{1}{2} \|x^* - x_n^*\|_X \leq \frac{\|K^{-1}\|_{Y \rightarrow X} (E_n(y)_{\hat{q}}^* + u_n\|y\|_Y)}{1 - u_n}.
\]

Then we finally find

\[
\|x^* - x_n^*\|_X \leq \frac{2\|K^{-1}\|_{Y \rightarrow X} (E_n(y)_{\hat{q}}^* + u_n\|y\|_Y)}{1 - u_n}.
\]

The proof is complete.
