Abstract

Let \( \Gamma \) be the first Grigorchuk group. According to a result of Bartholdi, the only left Engel elements of \( \Gamma \) are the involutions. This implies that the set of left Engel elements of \( \Gamma \) is not a subgroup. Of particular interest is to wonder whether this happens also for the sets of bounded left Engel elements, right Engel elements, and bounded right Engel elements of \( \Gamma \). Motivated by this, we prove that these three subsets of \( \Gamma \) coincide with the identity subgroup.

2010 Mathematics Subject Classification: 20F45, 20E08
Keywords: Engel element, Grigorchuk group

1 Introduction

Let \( G \) be a group. An element \( g \in G \) is called a left Engel element if for any \( x \in G \) there exists a positive integer \( n = n(g,x) \) such that \([x,n]g = 1\). As usual, the commutator \([x,n]g\) is defined inductively by the rules

\[
[x,1]g = [x,g] = x^{-1}x^g \quad \text{and, for } n \geq 2, \quad [x,n]g = [[x,n-1]g],g).
\]

If \( n \) can be chosen independently of \( x \), then \( g \) is called a left \( n \)-Engel element, or less precisely a bounded left Engel element. Similarly, \( g \) is a right Engel element or a bounded right Engel element if the variable \( x \) appears on the right. The group \( G \) is then called Engel (or bounded Engel, resp.) if all its elements are both left and right Engel (or bounded Engel, resp.). We

∗The authors are members of National Group for Algebraic and Geometric Structures, and their Applications (GNSAGA–INdAM).
denote by \( L(G), \mathcal{L}(G), R(G) \) and \( \mathcal{R}(G) \) respectively the sets of left Engel elements, bounded left Engel elements, right Engel elements, and bounded right Engel elements of \( G \). It is clear that these four subsets are invariant under automorphisms of \( G \). Furthermore, by a well-known result of Heineken (see [10, 12.3.1]), we have

\[
R(G)^{-1} \subseteq L(G) \quad \text{and} \quad \mathcal{R}(G)^{-1} \subseteq \mathcal{L}(G). \quad (*)
\]

It is a very long-standing question whether the sets \( L(G), \mathcal{L}(G), R(G) \) and \( \mathcal{R}(G) \) are subgroups of \( G \) (see Problems 16.15 and 16.16 in [8]). There are several classes of groups for which this is true (see [1] for an account; see also [2, 11]). On the other hand the question is still open, except for \( L(G) \) when \( G \) is a 2-group. In fact, in this case, one can easily see that any involution is a left Engel element [1, Proposition 3.3]. However, according to an example of Bludov, there exists a 2-group generated by involutions with an element of order four which is not left Engel ([5], see [9] for a proof). This suggests the following question.

**Question (Bludov).** Assuming that \( G \) is not a 2-group, is \( L(G) \) a subgroup of \( G \)?

We point out that the group \( G \) considered by Bludov is based on the (first) Grigorchuk group \([7]\), that we denote throughout by \( \Gamma \). More precisely, \( G \) is the wreath product \( D_8 \ltimes \Gamma^4 \) where \( D_8 \) is the dihedral group of order 8. Since \( \Gamma \) is a 2-group generated by involutions, one might wonder whether \( \Gamma \) is an Engel group but the answer is negative, as shown by Bartholdi:

**Theorem 1.1** ([3], see also [4]). Let \( \Gamma \) be the first Grigorchuk group. Then

\[
L(\Gamma) = \{ g \in \Gamma \mid g^2 = 1 \}.
\]

In particular, \( \Gamma \) is not an Engel group.

The question now arises: are \( \mathcal{L}(\Gamma) \), \( L(\Gamma) \) and \( \mathcal{R}(\Gamma) \) subgroups of \( \Gamma \)? Recall that \( \Gamma \) is just-infinite, that is, \( \Gamma \) is an infinite group all of whose proper quotients are finite. As a consequence, if \( \mathcal{L}(\Gamma) \) were a (proper) subgroup of \( \Gamma \), then \( \mathcal{L}(\Gamma) \) would be finitely generated and, by Theorem 1.1, also abelian. Hence \( \mathcal{L}(\Gamma) \) should be finite and therefore trivial, being \( \Gamma \) an infinite 2-group and \( \mathcal{L}(\Gamma) \) of finite index. Notice also that, by (7), the same holds for \( R(\Gamma) \) and \( \mathcal{R}(\Gamma) \).

Motivated by this, in the present note we prove the following theorem.

**Theorem 1.2.** Let \( \Gamma \) be the first Grigorchuk group. Then

\[
\mathcal{L}(\Gamma) = R(\Gamma) = \mathcal{R}(\Gamma) = \{ 1 \}.
\]

The proof of Theorem 1.2 will be given in the next section.
2 The proof

Before proving Theorem 1.2, we recall how the Grigorchuk group \( \Gamma \) is defined. We also collect some properties of \( \Gamma \) on which depends our proof. For a more detailed account on \( \Gamma \), we refer to [6, Chapter 8].

Let \( T \) be the regular binary rooted tree with vertices indexed by \( X^* \), the free monoid on the alphabet \( X = \{0, 1\} \). An automorphism of \( T \) is a bijection of the vertices that preserves incidence. The set \( \text{Aut} \, T \) of all automorphisms of \( T \) is a group with respect to composition. The stabilizer \( \text{st}(n) \) of the \( n \)th level of \( T \) is the normal subgroup of \( \text{Aut} \, T \) consisting of the automorphisms leaving fixed all words of length \( n \).

If an automorphism \( g \) fixes a vertex, then the restriction \( g_i \) of \( g \) to the subtree hanging from this vertex induces an automorphism of \( T \). In particular, if \( g \in \text{st}(n) \) then \( g_i \) is defined for \( i = 1, \ldots, 2^n \), and one can consider the injective homomorphism

\[
\psi_n : g \in \text{st}(1) \mapsto (g_1, \ldots, g_{2^n}) \in \text{Aut} \, T \times 2^n \times \text{Aut} \, T.
\]

We write \( \psi \) instead of \( \psi_1 \). Assuming \( \psi(g) = (g_1, g_2) \), it is easy to see that

\[
\psi(g^a) = (g_2, g_1),
\]

where \( a \) is the rooted automorphism of \( T \) corresponding to the permutation \( (01) \); this will be used freely in the sequel.

The Grigorchuk group \( \Gamma \) is the subgroup of \( \text{Aut} \, T \) generated by the rooted automorphism \( a \), and the automorphisms \( b, c, d \in \text{st}(1) \) which are defined recursively as follows:

\[
\psi(b) = (a, c), \quad \psi(c) = (a, d), \quad \psi(d) = (1, b).
\]

Moreover,

\[
\Gamma = \langle a \rangle \rtimes \text{st}_T(1)
\]

where \( \text{st}_T(1) = \Gamma \cap \text{st}(1) \). Recall also that \( \Gamma \) is spherically transitive (i.e., it acts transitively on each level of \( T \)) and it has a subgroup \( K \) of finite index such that \( \psi(K) \supseteq K \times K \). In other words, \( \Gamma \) is regular branch over \( K \).

For the proof of Theorem 1.2 we require two lemmas concerning commutators between specific elements of \( \Gamma \).

**Lemma 2.1.** Let \( x \in \Gamma \) be an involution and \( y \in \text{st}_T(1) \), with \( \psi(y) = (k, 1) \). Suppose \( x = ag \), where \( g \in \text{st}_T(1) \) and \( \psi(g) = (g_1, g_2) \). Then, for every \( m \geq 1 \), we have

\[
\psi([y, m \, x]) = (k(-1)^m 2^{m-1}, (k g_2) (-1)^{m-1} 2^{m-1}).
\]

**Proof.** Since \( a^2 = 1 \), we have \( (ag)^2 = 1 \) and so \( g^a = g^{-1} \). Thus

\[
(g_2, g_1) = \psi(g^a) = \psi(g^{-1}) = (g_1^{-1}, g_2^{-1}),
\]

Moreover,
from which it follows that $g_2 = g_1^{-1}$.

We now proceed by induction on $m$. The case $m = 1$ is clear, indeed

$$\psi([y, ag]) = \psi(y^{-1}y^a) = (k^{-1}, 1)(1, k^{g_2}) = (k^{-1}, k^{g_2}).$$

Let $m > 1$. Then, by using the induction hypothesis and that $g_2g_1 = 1$, we get

$$\psi([y, m\ ag]) = \psi((y, m-1\ ag)(y, m-1\ ag)^a)$$

$$= (k^{(-1)^m 2^{m-2}}, (k^{g_2})(-1)^{m-1} 2^{m-2}) \left((k^{g_2g_1})(-1)^{m-2} 2^{m-2}, (k^{g_2})(-1)^{m-1} 2^{m-2}\right)$$

$$= (k^{(-1)^m 2^{m-1}}, (k^{g_2})(-1)^{m-1} 2^{m-1}),$$

as desired. \hfill \Box

Lemma 2.2. Let $x \in \Gamma$ and $y \in \text{st}_\Gamma(1)$, with $\psi(y) = (y_1, y_2)$. Suppose $x = ag$, where $g \in \text{st}_\Gamma(1)$ and $\psi(g) = (g_1, g_2)$. Then, for every $m \geq 1$, we have

$$\psi([x, m+1\ y]) = \psi(([y_1^{-1}g_1, m\ y_1]y_1, ([y_1^{-1}g_2, m\ y_2]y_2)).$$

Proof. Of course, $[x, m\ y] \in \text{st}_\Gamma(1)$ for every $n \geq 1$. Thus

$$\psi([x, y]) = \psi((y_1^{-1})^2y) = \psi((y_1^{-1})^a)\psi(g)\psi(y) = ((y_2^{-1})g_1, (y_1^{-1})g_2)(y_1, y_2)$$

$$= ((y_2^{-1})g_1y_1, (y_1^{-1})g_2y_2).$$

It follows that

$$\psi([x, y, y]) = [\psi([x, y]), \psi(y)]$$

$$= [((y_2^{-1})g_1y_1, (y_1^{-1})g_2y_2), (y_1, y_2)]$$

$$= [([y_2^{-1}]g_1y_1, y_1], ([y_1^{-1}]g_2y_2, y_2)]$$

$$= (([y_2^{-1}]g_1, y_1)^y_1, ([y_1^{-1}]g_2, y_2)^y_2).$$

This proves the result when $m = 1$. Let $m > 1$. Then, by induction, we conclude that

$$\psi([x, m+1\ y]) = [\psi([x, m\ y]), \psi(y)]$$

$$= [([y_2^{-1}]g_1, m-1\ y_1]y_1, ([y_1^{-1}]g_2, m-1\ y_2)y_2), (y_1, y_2)]$$

$$= (([y_2^{-1}]g_1, m\ y_1]y_1, ([y_1^{-1}]g_2, m\ y_2)y_2).$$

\hfill \Box

We are now ready to prove Theorem 2.2.
Proof of Theorem 1.2. Let $x$ be a nontrivial Engel element of $\Gamma$. First, notice that we may assume $x \notin \text{st}_\Gamma(1)$. In fact, if $x \in \text{st}_\Gamma(n) \setminus \text{st}_\Gamma(n+1)$ then

$$\psi_n(x) = (x_1, \ldots, x_{2n})$$

where all the $x_i$’s are Engel elements of the same kind of $x$ and one of $x_i$’s does not belong to $\text{st}_\Gamma(1)$. Hence $x = ag$, for some $g \in \text{st}_\Gamma(1)$ with $\psi(g) = (g_1, g_2)$. We distinguish two cases: $x \in \overline{L}(\Gamma)$ and $x \in R(\Gamma)$.

Assume $x \in \overline{L}(\Gamma)$. Then $[y, n x] = 1$ for some $n \geq 1$ and for every $y \in \Gamma$. Also $x^2 = 1$, by Theorem 1.1. Since $K$ is not of finite exponent, we can take $k \in K$ of order greater than $2^{m-1}$ for some $m$. On the other hand $\psi(K) \supseteq K \times K$, so there exists $y \in K \subseteq \text{st}_\Gamma(1)$ such that $(k, 1) = \psi(y)$. Thus, by Lemma 2.1, we have

$$(1, 1) = \psi(1) = \psi([y, n x]) = \left(k^{(-1)^m 2^{m-1}}, (k^{g_2})(-1)^m 2^{m-1}\right).$$

It follows that $k^{2^{m-1}} = 1$, a contradiction. This proves that $\overline{L}(\Gamma) = \{1\}$.

Assume $x \in R(\Gamma)$. Since $K$ is not abelian, it cannot be an Engel group by Theorem 1.1. Thus $[h, m y_1] \neq 1$ for some $h, y_1 \in K$ and for every $n \geq 1$. Put $y_2 = [y_1, h]^{g_1^{-1}}$. Obviously, $y_2 \in K$ and $(y_2^{-1})^{g_1} = [h, y_1]$. Now $\Gamma$ is regular branch over $K$, so there exists $y \in K \subseteq \text{st}_\Gamma(1)$ such that $\psi(y) = (y_1, y_2)$. Furthermore, there is $m = m(x, y) \geq 1$ such that $[x, m y] = 1$. Applying Lemma 2.2, we get

$$(1, 1) = \psi(1) = \psi([x, m+1 y]) = (([y_2^{-1}]^{g_1}, m y_1)^{g_1}, ([y_1^{-1}]^{g_2}, [y_2]^{g_2}), ([h, m+1 y_1]^{g_1}, ([y_1^{-1}]^{g_2}, [y_2]^{g_2})].$$

This implies that $[h, m+1 y_1] = 1$, which is a contradiction. Therefore $R(\Gamma) = \overline{R}(\Gamma) = \{1\}$, and the proof of Theorem 1.2 is complete.

Acknowledgements. The authors would like to thank Prof. Gustavo A. Fernández-Alcober for interesting and helpful conversations (at cafetería).
