Abstract
We define a stratification of Deligne–Lusztig varieties and their parahoric analogues which we call the Drinfeld stratification. In the setting of inner forms of \( \text{GL}_n \), we study the cohomology of these strata and give a complete description of the unique closed stratum. We state precise conjectures on the representation-theoretic behavior of the stratification. We expect this stratification to play a central role in the investigation of geometric constructions of representations of \( p \)-adic groups.

1 Introduction
Like the classical upper half-plane, its nonarchimedean analogue—the Drinfeld upper half-plane—appears naturally in a wide range of number theoretic, representation theoretic, and algebro-geometric contexts. For finite fields, the \( \ell \)-adic étale
cohomology of the Drinfeld upper half-plane $\mathbb{P}^1(\overline{\mathbb{F}}_q) \setminus \mathbb{P}^1(\mathbb{F}_q)$ with coefficients in nontrivial rank-1 local systems, is known to realize the cuspidal irreducible representations of $\text{GL}_2(\mathbb{F}_q)$. One can generalize this to $\text{GL}_n(\mathbb{F}_q)$ by projectivizing the complement of all rational sub-vector spaces of $V = \mathbb{F}_q^\oplus n$. This is the Drinfeld upper half-space for $\mathbb{F}_q$. In this paper, we consider a stratification of the Drinfeld upper half-space induced by “intermediate” Drinfeld upper half-spaces of smaller dimension sitting inside $\mathbb{P}(V)$.

In earlier work [9], we proved that for inner forms of $\text{GL}_n$, Lusztig’s loop Deligne–Lusztig set [15] is closely related to a finite-ring analogue of the Drinfeld upper half-space. This allowed us to endow this set with a scheme structure (a statement which is still conjectural for any group outside $\text{GL}_n$) and define its cohomology. Under a regularity condition, we proved in [9] that the cohomology of loop Deligne–Lusztig varieties for inner forms of $\text{GL}_n$ realizes certain irreducible supercuspidal representations and described these representations within the context of the local Langlands and Jacquet–Langlands correspondences. After some serious work in [8], we are able to relax this regularity condition to something quite general, but our work still further depends on a formal degree calculation of representations appearing in the cohomology of these loop Deligne–Lusztig varieties. This is a highly nontrivial calculation which we obtain in the present paper by studying the cohomology of a stratification—the Drinfeld stratification—which comes from the aforementioned stratification of the Drinfeld upper half-space.

We moreover frame the Drinfeld stratification in the general context of [7], where we studied a class of varieties $X_h$ associated to parahoric subgroups of $\text{a(ny)}$ connected reductive group $G$ which splits over an unramified extension. We define a stratification of $X_h$ indexed by certain twisted Levi subgroups of $G$, initiate the study of these strata, and, in due course, supply the necessary input for the formal degree calculation in [8].

We focus on the setting of inner forms of $\text{GL}_n$ and prove the first foundational representation-theoretic traits of the cohomology of the Drinfeld stratification: irreducibility (Theorem 5.2.1) and a special character formula (Proposition 5.3.1). Using Theorem 5.2.1, in Sect. 6 we prove that the torus eigenspaces in the cohomology of the unique closed Drinfeld stratum is supported in a single (possibly non-middle) degree. Furthermore, this stratum is a maximal variety in the sense of Boyarchenko–Weinstein [2]: the number of rational points of the closed Drinfeld stratum attains its Weil–Deligne bound. Our analysis relies on techniques developed in [5] in the special case of division algebras and gives some context for what we expect to be the role of maximal varieties in these Deligne–Lusztig varieties for $p$-adic groups.

In practice, it is sometimes only possible to work directly with the Drinfeld stratification of the parahoric Deligne–Lusztig varieties $X_h$ instead of with the entire $X_h$. In this paper, for example, the maximality of the closed stratum allows us to give an exact formula (Corollary 6.6.1) for the formal degree of the associated representation of the $p$-adic group. We prove a comparison theorem in [8] relating the Euler characteristic of this stratum to that of $X_h$. This formal degree input, by comparison with Corwin–Moy–Sally [10], allows us to obtain a geometric supercuspidality result in [8].

We finish the present paper with a precise formulation of some conjectures (Conjectures 7.1.1 and 7.2.1) which describe what we expect to be the shape of the cohomology
of the Drinfeld stratification and its relation to the cohomology of loop Deligne–Lusztig varieties. In the “Appendix”, we present an analysis of the fibers of the natural projection maps $X_h \to X_{h-1}$; we believe this could be a possible approach to proving Conjecture 7.2.1 and may be of independent interest. It would be interesting to see if the Drinfeld stratification plays a role in connections to orbits in finite Lie algebras, à la work of Chen [6].

2 Notation

Let $k$ be a nonarchimedean local field with residue field $\mathbb{F}_q$ and let $\bar{k}$ denote the completion of the maximal unramified extension of $k$. We write $\mathcal{O}_{\bar{k}}$ and $\mathcal{O}_k$ for the rings of integers of $\bar{k}$ and $k$, respectively, and let $\sigma$ be a uniformizer of $k$ (and hence of $\bar{k}$). For any positive integer $m$ and any $l \in \mathbb{Z}$, we let $[l]_m \in \{1, \ldots, m\}$ denote the unique element representing the coset $l + m\mathbb{Z} = [l]_m + m\mathbb{Z}$.

The setting of Sect. 3

In Sect. 3 we work in the following general set-up. Let $G$ be a connected reductive group over $k$ such that the base change $G_{\bar{k}}$ to $\bar{k}$ is split and let $F$ denote a Frobenius associated to the $k$-rational structure on $G$. Let $T \hookrightarrow G$ be a $k$-rational, $\bar{k}$-split maximal torus in $G$. Let $\mathcal{B}(G, \bar{k})$ denote the Bruhat–Tits building of the adjoint group of $G$ over $\bar{k}$ and let $\mathcal{A}(T) \subset \mathcal{B}(G, \bar{k})$ denote the apartment of $T$. Note that there is a natural action of $F$ on $\mathcal{B}(G, \bar{k})$ and that since $T$ is $k$-rational, the apartment $\mathcal{A}(T)$ is $F$-stable.

The setting of the rest of the paper

With the exception of Sect. 3, we will take $G$ to be an inner form of $\text{GL}_n$ defined over $k$. Let $\sigma \in \text{Gal}(\bar{k}/k)$ denote the Frobenius which induces the $q$th-power automorphism on the residue field $\mathbb{F}_q$. Abusing notation, we also let $\sigma$ denote the map $\text{GL}_n(\bar{k}) \to \text{GL}_n(\bar{k})$ by applying $\sigma$ to each matrix entry. The inner forms of $\text{GL}_n$ are indexed by integers $0 \leq \kappa \leq n - 1$; fix such an integer. Throughout the paper, we write $\kappa/n = k_0/n_0$ where $(k_0, n_0) = 1$, and we set $\kappa = k_0 n'$. We will define (Definition 4.1.1) a particular element $b_{\text{cox}}$ with $\det(b_{\text{cox}}) = \kappa$ and set $G = J_{b_{\text{cox}}}$ (the $\sigma$-stabilizer of $b_{\text{cox}}$) with the $k$-rational structure induced by the Frobenius

$$F: \text{GL}_n(\bar{k}) \to \text{GL}_n(\bar{k}), \quad g \mapsto b_{\text{cox}} \sigma(g) b_{\text{cox}}^{-1}.$$ 

Note that $G \cong \text{GL}_{n'}(D_{k_0/n_0})$, where $D_{k_0/n_0}$ denotes the division algebra over $k$ of dimension $n_0^2$ with Hasse invariant $k_0/n_0$. Let $\mathcal{T}$ denote the set of diagonal matrices in $G$. Let $x$ be the unique point in the intersection $\mathcal{A}(T) \cap \mathcal{B}(\text{GL}_n, \bar{k})^F$. Note that $T(k)$ is isomorphic to the multiplicative group of the unramified degree-$n$ extension of $k$.

If $k$ has characteristic $p$, we let $\mathbb{W}(A) = A[[\sigma]]$ for any $\mathbb{F}_p$-algebra $A$ and write $[a_i]_{i \geq 0}$ to denote the element $\sum_{i \geq 0} a_i \sigma^i \in \mathbb{W}(A)$. If $k$ has characteristic zero, we let
\[ \mathbb{W} = W_{O_k} \times_{\text{Spec} O_k} \text{Spec } \mathbb{F}_q, \] where \( W_{O_k} \) is the \( O_k \)-ring scheme of \( O_k \)-Witt vectors [12, Section 1.2]. Following the notation of \textit{op. cit.} we write the elements of \( \mathbb{W}(A) \) as \( [a_i]_{i \geq 0} \) where \( a_i \in A \). We may now talk about \( \mathbb{W} \) uniformly, regardless of the characteristic of \( k \). As usual, we have the Frobenius and Verschiebung morphisms

\[
\sigma : \mathbb{W} \to \mathbb{W}, \quad [a_i]_{i \geq 0} \mapsto [a_i^q]_{i \geq 0},
\]

\[
V : \mathbb{W} \to \mathbb{W}, \quad [a_i]_{i \geq 0} \mapsto [0, a_0, a_1, \ldots].
\]

For any \( h \in \mathbb{Z}_{\geq 0} \), let \( \mathbb{W}_h = \mathbb{W}/V^h \mathbb{W} \) denote the corresponding truncated ring scheme.

**Summary of the schemes**

We give an overview of the various schemes appearing in this paper. We hope this will be a helpful reference point for the reader. In Sect. 3, we define in a very general setting three schemes \( S_h, X_h \), and \( X_h(b, w) \) (Definitions 3.1.1, 3.1.1 and 3.2.1). We then define (Definition 3.3.1) a stratification for \( S_h \) indexed by certain twisted Levi subgroups of \( G \), and use this to define a corresponding stratification for \( X_h \) (Definition 3.3.2).

In Sect. 4, we study these varieties in the special case that \( G \) is an inner form of \( \text{GL}_n \) corresponding to the fixed integer \( \kappa \). We comment that in this paper, the role of \( X_h(b, w) \) as an alternative viewpoint to \( X_h \) (Sect. 4.5). For most of this paper, we implicitly use the identification \( X_h = X_h(b_{\text{cox}}, b_{\text{cox}}) \), but our calculations in “Appendix A” require us to take advantage of an isomorphism \( X_h \cong X_h(b, b_{\text{cox}}) \) for a different choice of \( b \). This flexibility has been proven to be very useful—as an additional example, see [9].

For our chosen inner form \( G \) of \( \text{GL}_n \), the Drinfeld stratification of \( S_h, X_h \) is indexed by divisors \( r \) of \( n' \) (Definition 4.3.2). We will define subschemes \( S_h^{(r)} \subset S_h \) and \( X_h^{(r)} \subset X_h \) which form the commutative diagram

\[
\begin{array}{ccc}
S_h^{(r)} & \hookrightarrow & S_h \\
\downarrow & & \downarrow \\
X_h^{(r)} & \hookrightarrow & X_h 
\end{array}
\]

where the vertical maps are quotients by an affine space. The \( r \)th Drinfeld stratum (4.1) of \( X_h \) is

\[
X_{h,r} = X_h^{(r)} \setminus \bigcup_{r|s|n', r < s} X_h^{(s)}
\]

and its closure in \( X_h \) is \( X_h^{(r)} \). In Sect. 4.4, we give a description of \( X_{h,r} \) in terms of Drinfeld upper half-spaces and a finite-ring analogue of an isocrystal. The unique closed Drinfeld stratum is \( X_{h,n'} \); specializing Lemma 3.3.3, we have
\[
X_{h,n'} = X_h^{(n')} = \bigsqcup_{g \in G_h(F_q)} g \cdot X_h^1,
\]
where \(X_h^1 = X_h \cap \ker(G_h \to G_1)\).

## 3 The Drinfeld stratification

In this section only, we let \(G\) be any connected reductive group over \(k\) which splits over \(\tilde{k}\). Let \(F\) denote a Frobenius associated to the \(k\)-rational structure on \(G\). Fix a \(k\)-rational, \(\tilde{k}\)-split maximal torus \(T \subset G\), let \(x \in \mathcal{A}(T) \cap \mathcal{B}(G, \tilde{k})^F\), and let \(G_{x,0}\) be the attached parahoric model. The \(\mathcal{O}_k\)-scheme \(G_{x,0}\) has a Moy–Prasad filtration \([17,19]\) given by a decreasing series of normal subgroups \(G_{x,r} \subset G_{x,0}\) for \(r \in \mathbb{R}_{\geq 0}\) and we furthermore define the subgroup \(G_{x,r^+} := \bigcup_{s \geq r} G_{x,s}\) of \(G_{x,r}\).

Let \(h \geq 1\) be an integer. There is a smooth affine group scheme \(\mathbb{G}_h\) over \(\mathbb{F}_q\) such that

\[
\mathbb{G}_h(F_q) = G_{x,0}(\mathcal{O}_{\tilde{k}})/G_{x,(h-1)+}(\mathcal{O}_{\tilde{k}}), \quad \mathbb{G}_h(\mathbb{F}_q) = G_{x,0}(\mathcal{O}_{\tilde{k}})/G_{x,(h-1)+}(\mathcal{O}_{\tilde{k}})
\]

(see [7, Section 2.5] for more details). Following [7, Section 2.6], for any closed subgroup scheme \(J \subset G_{\tilde{k}}\), we may attach a subgroup \(\mathbb{J}_h \subset \mathbb{G}_h(F_q)\). For any integer \(1 \leq s \leq h\), we write \(\mathbb{J}_s := \ker(\mathbb{J}_h \to \mathbb{J}_s)\).

Pick a \(\tilde{k}\)-rational Borel subgroup \(B \subset G_{\tilde{k}}\) containing \(T\) and let \(U\) be the unipotent radical of \(B\). The subgroups \(T \subset G, U \subset G_{\tilde{k}}\) have associated subgroups \(\mathbb{T}_h \subset \mathbb{G}_h, \mathbb{U}_h \subset \mathbb{G}_h(\mathbb{F}_q)\) such that

\[
\mathbb{T}_h(F_q) = (T(k) \cap G_{x,0}(\mathcal{O}_{\tilde{k}}))/(T(k) \cap G_{x,(h-1)+}(\mathcal{O}_{\tilde{k}})),
\]
\[
\mathbb{T}_h(\mathbb{F}_q) = (T(\tilde{k}) \cap G_{x,0}(\mathcal{O}_{\tilde{k}}))/(T(\tilde{k}) \cap G_{x,(h-1)+}(\mathcal{O}_{\tilde{k}})),
\]
\[
\mathbb{U}_h(\mathbb{F}_q) = (U(\tilde{k}) \cap G_{x,0}(\mathcal{O}_{\tilde{k}}))/(U(\tilde{k}) \cap G_{x,(h-1)+}(\mathcal{O}_{\tilde{k}}))
\]

(Note here that \(\mathbb{U}_h\) is defined over \(\mathbb{F}_q\) but may not be defined over \(\mathbb{F}_q\) as \(U\) may not be \(k\)-rational.)

### 3.1 The schemes \(S_h\) and \(X_h\)

The central object of study is \(X_h\):

**Definition 3.1.1** Define the \(\mathbb{F}_q\)-scheme

\[
X_h := \{x \in \mathbb{G}_h : x^{-1}F(x) \in \mathbb{U}_h\}/(\mathbb{U}_h \cap F^{-1}(\mathbb{U}_h))
\]

\(X_h\) comes with a natural action of \(\mathbb{G}_h(\mathbb{F}_q) \times \mathbb{T}_h(\mathbb{F}_q)\) by left- and right-multiplication:

\[
(g, t) \cdot x = gxt, \quad \text{for} \ (g, t) \in \mathbb{G}_h(\mathbb{F}_q) \times \mathbb{T}_h(\mathbb{F}_q), x \in X_h.
\]
In some contexts, it will be more convenient to study \( S_h \):

**Definition 3.1.2** Define the \( \overline{\mathbb{F}}_q \)-scheme

\[
S_h := \{ x \in \mathbb{G}_h : x^{-1} F(x) \in \mathbb{U}_h \}.
\]

So, \( S_h \) is the closed subscheme of \( \mathbb{G}_h \) obtained by pulling back \( \mathbb{U}_h \) along the (finite étale) Lang map \( \mathbb{G}_h \to \mathbb{G}_h, \ g \mapsto g^{-1} F(g) \). Note that \( S_h \) comes with the same natural action of \( \mathbb{G}_h(\overline{\mathbb{F}}_q) \times \mathbb{T}_h(\mathbb{F}_q) \) as \( X_h \).

Observe that since \( \mathbb{U}_h \cap F^{-1}(\mathbb{U}_h) \) is an affine space, the cohomology of \( X_h \) and \( S_h \) differs only by a shift, and in particular, for any \( \theta : \mathbb{T}_h(\mathbb{F}_q) \to \overline{\mathbb{Q}}_\ell \), we have

\[
H^\ell_c(X_h, \overline{\mathbb{Q}}_\ell)[\theta] = H^\ell_c(S_h, \overline{\mathbb{Q}}_\ell)[\theta]
\]
as elements of the Grothendieck group of \( \mathbb{G}_h(\mathbb{F}_q) \).

### 3.2 The scheme \( X_h(b, w) \)

In this subsection only, we further assume that \( G \) is quasisplit over \( k \) and \( B \subset G \) is \( k \)-rational. In this section, we write \( \sigma = F \) for our \( q \)-Frobenius associated to the \( k \)-rational structure on \( G \). Note that by assumption, the unipotent radical \( U \) of \( B \) is \( \sigma \)-stable.

**Definition 3.2.1** Let \( b, w \in G(\bar{k}) \). Assume that \( b, w \) both normalized the subgroups \( G_{x,0}(\mathcal{O}_{\bar{k}}) \) and \( G_{x,(h-1)+}(\mathcal{O}_{\bar{k}}) \) of \( G(\bar{k}) \), and additionally assume that \( w \) normalizes \( T(\bar{k}) \). Define the \( \overline{\mathbb{F}}_q \)-scheme

\[
X_h(b, w) := \{ x \in \mathbb{G}_h : x^{-1} b \sigma(x) \in \mathbb{U}_h w \mathbb{U}_h \}/\mathbb{U}_h,
\]

where the condition \( x^{-1} b \sigma(x) \in \mathbb{U}_h w \mathbb{U}_h \) means the following: For any lift \( \bar{x} \in G \) of \( x \in \mathbb{G}_h \), the element \( \bar{x}^{-1} b \sigma(\bar{x}) \) is an element of \( (U \cap G_{x,0}) w(U \cap G_{x,0}) G_{x,(h-1)+} \subset G \). More precisely, \( X_h(b, w) = S_h(b, w)/\mathbb{U}_h \), where \( S_h(b, w) \) is the reduced \( \overline{\mathbb{F}}_q \)-subscheme of \( \mathbb{G}_h \) such that \( S_h(b, w)(\overline{\mathbb{F}}_q) \) is equal to the image of \( \{ x \in G_{x,0}(\mathcal{O}_{\bar{k}}) : x^{-1} b \sigma(x) \in (U(\bar{k}) \cap G_{x,0}(\mathcal{O}_{\bar{k}})) w(U(\bar{k}) \cap G_{x,0}(\mathcal{O}_{\bar{k}})) G_{x,(h-1)+}(\mathcal{O}_{\bar{k}}) \} \) in \( \mathbb{G}_h(\overline{\mathbb{F}}_q) \). Note that \( X_h(b, w) \) comes with a natural action by left- and right-multiplication of \( G_h(b) \) and \( T_h(w) \), where \( G_h(b) \subset \mathbb{G}_h(\overline{\mathbb{F}}_q) \) is the image of \( \{ g \in G_{x,0}(\mathcal{O}_{\bar{k}}) : b \sigma(g)b^{-1} = g \} \) and \( T_h(w) \subset \mathbb{T}_h(\overline{\mathbb{F}}_q) \) is the image of \( \{ t \in T(\bar{k}) \cap G_{x,0}(\mathcal{O}_{\bar{k}}) : w \sigma(t)w^{-1} = t \} \).

The next lemma is a one-line computation; we record it for easy reference.

**Lemma 3.2.2** Let \( \gamma \in G_{x,0}(\mathcal{O}_{\bar{k}}) \). Then we have an isomorphism

\[
X_h(b, w) \to X_h(\gamma^{-1} b \sigma(\gamma), w), \quad x \mapsto \overline{\gamma}^{-1} x,
\]

where \( \overline{\gamma} \) is the image of \( \gamma \) in the quotient \( \mathbb{G}_h(\overline{\mathbb{F}}_q) \).
Lemma 3.2.3 Consider the morphism \( F : (G_h)_{\mathbb{F}_q} \rightarrow (G_h)_{\mathbb{F}_q} \) given by \( g \mapsto b \sigma(g)b^{-1} \). If \( wG_{x,0}b^{-1} = G_{x,0} \) and \( F(U_h) = wU_hb^{-1} \), then
\[
X_h(b, w) = X_h,
\]
where \( X_h \) is the \( \mathbb{F}_q \)-scheme in Definition 3.1.1 associated to the group scheme \( (G_h)_{\mathbb{F}_q} \) endowed with the \( \mathbb{F}_q \)-rational structure associated to the \( q \)-Frobenius \( F \).

Proof. We have
\[
X_h(b, w) = \{ x \in G_h : x^{-1}F(x) \in \mathbb{U}_h w\mathbb{U}_hb^{-1} \}/\mathbb{U}_h \\
= \{ x \in G_h : x^{-1}F(x) \in \mathbb{U}_h F(\mathbb{U}_h) \}/\mathbb{U}_h \\
= \{ x \in G_h : x^{-1}F(x) \in \mathbb{U}_h \}/(\mathbb{U}_h \cap F^{-1}\mathbb{U}_h) = X_h. \quad \square
\]

3.3 The Drinfeld stratification for \( S_h \)

Let \( L \) be a \( k \)-rational twisted Levi subgroup of \( G \) and assume that \( L \) contains \( T \). Recall that a \( k \)-rational subgroup \( L \subset G \) is a twisted Levi if \( L_{\mathbb{F}_\ell} \) is a Levi subgroup of \( G_{\mathbb{F}_\ell} \).

Note also that the condition that \( L \) contains \( T \) forces \( L \) to be split over \( \mathbb{F}_\ell \). Following [7, Section 2.6], the schematic closure \( L_x \) in \( G_{x,0} \) is a closed subgroup scheme defined over \( \mathcal{O}_k \). Applying the “positive loop” functor to \( L_x \), for each positive integer \( h \) we can define a \( \mathbb{F}_q \)-scheme \( \mathbb{L}_h \) such that \( \mathbb{L}_h(\mathbb{F}_q) \) is the image of \( L_x(\mathcal{O}_k) \) in \( G_h(\mathbb{F}_q) \).

Definition 3.3.1 (Drinfeld stratification for \( S_h \)) Define
\[
S_h^{(L)} := \{ x \in G_h : x^{-1}F(x) \in (\mathbb{L}_h \cap \mathbb{U}_h)\mathbb{U}_h^1 \},
\]
where \((\mathbb{L}_h \cap \mathbb{U}_h)\mathbb{U}_h^1 \subset \mathbb{U}_h \) is the subgroup generated by \( \mathbb{L}_h \cap \mathbb{U}_h \) and \( \mathbb{U}_h^1 \) (which is normalized by \( \mathbb{L}_h \cap \mathbb{U}_h \)). Note that the subscheme \( S_h^{(L)} \) of \( S_h \) is closed and stable under the action of \( G_h(\mathbb{F}_q) \times \mathcal{T}_h(\mathbb{F}_q) \).

Definition 3.3.2 (Drinfeld stratification for \( X_h, X_h(b, w) \)) Define \( X_h^{(L)} \) to be the image of \( S_h^{(L)} \) under the surjection \( S_h \rightarrow X_h \). Recall that for any \( \gamma \in G_{x,0}(\mathcal{O}_k) \), we have \( X_h(b, w) \cong X_h(\gamma^{-1}b \sigma(\gamma), w) \) via \( x \mapsto \gamma^{-1}x \). If \( F(\mathbb{U}_h) = w\mathbb{U}_hb^{-1} \), then \( X_h = X_h(b, w) \); in this setting, let \( X_h(\gamma^{-1}b \sigma(\gamma), w)^{(L)} \) denote the image of \( X_h^{(L)} \).

Another subscheme of \( S_h \) which we may associate to the twisted Levi subgroup \( L \subset G \) is the intersection
\[
S_h \cap \mathbb{L}_h \mathbb{G}_h^1 = \{ x \in \mathbb{L}_h \mathbb{G}_h^1 : x^{-1}F(x) \in \mathbb{U}_h \}
\[
= \{ x \in \mathbb{L}_h \mathbb{G}_h^1 : x^{-1}F(x) \in (\mathbb{L}_h \cap \mathbb{U}_h)\mathbb{U}_h^1 \},
\]
where \( \mathbb{L}_h \mathbb{G}_h^1 \) denotes the subgroup scheme of \( \mathbb{G}_h \) generated by \( \mathbb{L}_h \) and \( \mathbb{G}_h^1 \) (which is normalized by \( \mathbb{L}_h \)). Note that \( S_h \cap \mathbb{L}_h \mathbb{G}_h^1 \) is stable under the action of \( \mathbb{L}_h(\mathbb{F}_q) \mathbb{G}_h^1(\mathbb{F}_q) \times \mathcal{T}_h(\mathbb{F}_q) \).
Lemma 3.3.3 Let $L$ be a $k$-rational twisted Levi subgroup of $G$ containing $T$. Then

$$S_h^{(L)} = \bigsqcup_{\gamma \in G_h(F_q)/(L_h(F_q)G_h^1(F_q))} \gamma \cdot (S_h \cap L_h G_h^1).$$

Proof Pick any $u \in \mathbb{U}_h(\mathbb{F}_q)U^1_h(\mathbb{F}_q)$. By surjectivity of the Lang map, there exists $x \in \mathbb{L}_h(\mathbb{F}_q)G_h^1(\mathbb{F}_q)$ and $y \in G_h(\mathbb{F}_q)$ such that $x^{-1}F(x) = u$ and $y^{-1}F(y) = u$. Then

$$(xy^{-1})^{-1}F(xy^{-1}) = yx^{-1}F(x) = F(y)^{-1} = yuF(y)^{-1} = yuu^{-1}y^{-1} = 1.$$ 

Therefore $xy^{-1} \in G_h(\mathbb{F}_q)$. The assertion now follows from the fact that the stabilizer of $S_h \cap L_h G_h^1$ in $G_h(\mathbb{F}_q) \times T_h(\mathbb{F}_q)$ is $\mathbb{L}_h(\mathbb{F}_q)G_h^1(\mathbb{F}_q) \times T_h(\mathbb{F}_q)$. \hfill $\Box$

By Lemma 3.3.3, we see:

Lemma 3.3.4 If $L$ is a twisted Levi subgroup of $G$ containing $T$, then for any character $\theta: T_h(\mathbb{F}_q) \to \overline{\mathbb{Q}}_\ell^\times$ and for all $i \geq 0$,

$$H^i_c(S_h^{(L)}, \overline{\mathbb{Q}}_\ell)[\theta] \cong \text{Ind}_{\mathbb{L}_h(\mathbb{F}_q)G_h^1(\mathbb{F}_q)}^{G_h(\mathbb{F}_q)}(H^i_c(S_h \cap \mathbb{L}_h G_h^1, \overline{\mathbb{Q}}_\ell)[\theta]).$$

4 The case of $\text{GL}_n$

In this section, we study the varieties introduced in Sect. 3 in the special case when $G$ is an inner form of $\text{GL}_n$. We emphasize that these varieties $S_h$, $X_h$, $X_h(b, w)$—at least a priori—depend on a choice of Borel subgroup containing the torus at hand. From now until the end of the paper, we work with the varieties associated with the Borel subgroup explicitly chosen in Sect. 4.2. We explicate (Sect. 4.3) the Drinfeld stratification for $S_h$, $X_h$, and certain $X_h(b, w)$, and give a description (Sect. 4.4) in terms of Drinfeld upper half-spaces and $\mathcal{Z}_h \subset \mathbb{W}_h^{\text{fin}}$, a finite-ring analogue of an isocrystal.

Let $\sigma \in \text{Gal}(\overline{k}/k)$ denote a lift of the $q$th-power Frobenius on the residue field $\mathbb{F}_q$. Abusing notation, also let

$$\sigma: \text{GL}_n(\overline{k}) \to \text{GL}_n(\overline{k}), \quad (M_{i,j})_{i,j=1,...,n} \mapsto (\sigma(M_{i,j}))_{i,j=1,...,n}.$$ 

For $b \in \text{GL}_n(\overline{k})$, let $J_b$ be the $\sigma$-stabilizer of $b$: for any $k$-algebra $R$,

$$J_b(R) := \{g \in \text{GL}_n(R \otimes_k \overline{k}) : g^{-1}b\sigma(g) = b\}.$$ 

$J_b$ is an inner form of the centralizer of the Newton point of $b$ (which is a Levi subgroup of $\text{GL}_n$), and we may consider

$$\text{GL}_n(\overline{k}) \to \text{GL}_n(\overline{k}), \quad g \mapsto b\sigma(g)b^{-1}.$$
to be an associated $q$-Frobenius for the $k$-rational structure on $J_b$. If $b$ is basic (i.e. the Newton point of $b$ is central), then $J_b$ is an inner form of $GL_n$, and moreover every inner form arises in this way. If $\kappa = \kappa_{GL_n}(b) := \text{val}(\det(b))$ and $b$ is basic, then $J_b(k) \cong GL_{n'}(D_{k_0/n_0})$ where $\kappa/n = k_0/n_0$, $(k_0, n_0) = 1$, and $\kappa = k_0n'$. Note that the isomorphism class of $J_b$ only depends on the $\sigma$-conjugacy class $[b] := \{g^{-1}b\sigma(g) : g \in GL_n(k)\}$. Recall from Sect. 2 that for any positive integer $m$ and any $l \in \mathbb{Z}$, we let $[l]_m \in \{1, \ldots, m\}$ denote the unique element representing the coset $l + m\mathbb{Z} = [l]_m + m\mathbb{Z}$.

Fix an integer $0 \leq \kappa \leq n - 1$. In the next sections, we will focus on representatives $b$ revolving around the Coxeter representative (Definition 4.1.1) and give explicit descriptions of the varieties $X_h$, $X_h(b, w)$, and their Drinfeld stratifications $\{X_h^{(r)}\}$, $\{X_h(b, w)^{(r)}\}$, where $r$ runs over the divisors of $n'$. The $X_h^{(r)}$, $X_h(b, w)^{(r)}$ are closed subvarieties of $X_h$, $X_h(b, w)$; we call the $r$th Drinfeld stratum

$$X_h^{(r)} \left( \bigcup_{r < r' \leq n'} X_h^{(r')} \right), \quad X_h(b, w)^{(r)} \left( \bigcup_{r < r' \leq n'} X_h(b, w)^{(r')} \right)$$

(4.1)

so that the closure of the $r$th Drinfeld stratum is $X_h^{(r)}$, $X_h(b, w)^{(r)}$. We denote the $r$th Drinfeld stratum of $X_h$ by $X_{h, r}$.

### 4.1 Explicit parahoric subgroups of $G$

Set

$$b_0 := \begin{pmatrix} 0 & 1 \\ 1_{n-1} & 0 \end{pmatrix}, \quad \text{and} \quad t_{\kappa,n} := \begin{cases} \text{diag}(1, \ldots, 1, \sigma^\kappa, \ldots, \sigma^\kappa) & \text{if } (\kappa, n) = 1, \\ \text{diag}(t_{k_0,n_0}, \ldots, t_{k_0,n_0}) & \text{otherwise.} \end{cases}$$

Note here that $t_{\kappa,n}$ is defined inductively in the sense that since $(k_0, n_0) = 1$, we take $t_{k_0,n_0} = \text{diag}(1, \ldots, 1, \sigma, \ldots, \sigma)$ to be the $n_0 \times n_0$ matrix where the first $n_0 - k_0$ entries are 1’s and the remaining $k_0$ entries are $\sigma$’s.

Fix an integer $e_{\kappa,n}$ such that $(e_{\kappa,n}, n) = 1$ and $e_{\kappa,n} = k_0 \mod n_0$. If $\kappa$ divides $n$ (i.e. $k_0 = 1$), we always take $e_{\kappa,n} = 1$.

**Definition 4.1.1** The Coxeter-type representative attached to $\kappa$ is $b_{\text{cox}} := b_0^{e_{\kappa,n}} \cdot t_{\kappa,n}$.

Define $G := J_{b_{\text{cox}}}$ with Frobenius

$$F : GL_n(\bar{k}) \to GL_n(\bar{k}), \quad g \mapsto b_{\text{cox}}\sigma(g)b_{\text{cox}}^{-1}$$

and define $T$ to be the set of diagonal matrices in $G$. Observe that $T$ is $F$-stable and that $T(k)$ is isomorphic to the multiplicative group of the unramified degree-$n$ extension.
of $k$. Since $T$ is elliptic, the intersection $\mathcal{A}(T) \cap \mathcal{B}(G, \mathcal{k})^F$ consists of a single point $x$, and an explicit and direct calculation of $x$ yields that $G_{x,0}$ consists of invertible matrices $(A_i,j)_{1 \leq i,j \leq n}$ where

$$A_{i,j} \in \begin{cases} \mathcal{W} & \text{if } [i]_{n_0} \geq [j]_{n_0}, \\ \mathcal{V} & \text{if } [i]_{n_0} < [j]_{n_0}. \end{cases}$$

For technical reasons, we will need to write down the relationship between the Coxeter element $b_0^{e_{x,n}}$ and the Coxeter element $b_0$. Define $\gamma$ to be the unique permutation matrix which (a) fixes the first elementary column vector and (b) has the property that $\gamma b_0^{e_{x,n}} \gamma^{-1} = b_0$. (4.2)

Note that one can express $\gamma$ explicitly as well: it corresponds to the permutation of $\{1, \ldots, n\}$ given by

$$i \mapsto [ (i - 1)e_{x,n} + 1].$$

### 4.2 An explicit description of $X_h$

The choices in this section are the same as those from [9, Section 7.7]. In the setting of division algebras, these choices also appear in [4,5].

Let $U_{up}$, $U_{low} \subset G_{\mathcal{k}}$ denote the subgroups of unipotent upper- and lower-triangular matrices. Define

$$U := \gamma^{-1} U_{low} \gamma, \quad U^{-} := \gamma^{-1} U_{up} \gamma.$$ (4.3)

Let $U_h$, $U^{-}_h$ be the associate subgroup schemes of $G_h$. By Chan and Ivanov [9, Lemma 7.12], we have an isomorphism of $\mathbb{F}_q$-schemes

$$(U_h \cap F U^{-}_h) \times (U_h \cap F^{-1} U_h) \to U_h, \quad (g, x) \mapsto x^{-1} g F(x).$$ (4.4)

We will need a refinement of this isomorphism later (see Lemma 4.3.1). Define

$$\mathcal{L}_h := (\mathcal{W}_h \oplus (\mathcal{W}_{h-1})^{\oplus n_0-1})^{\oplus n'}.$$ Write $t_{k,n} = \text{diag}(t_1, \ldots, t_n)$. Viewing any $v \in \mathcal{L}_h$ as a column vector, consider the associated matrix

$$\lambda(v) := \begin{pmatrix} v_1 & v_2 & v_3 & \cdots & v_n \end{pmatrix},$$ (4.5)

where $v_{[i e_{x,n} + 1]} := \sigma^{-[ik_0/n_0]} \cdot (b \sigma)^i(v)$ for $0 \leq i \leq n - 1$. (4.6)

**Lemma 4.2.1** We have

$$X_h = \{ x \in G_h : x^{-1} F(x) \in U_h \cap F(U^{-}_h) \} = \{ \lambda(v) \in G_h : v \in \mathcal{L}_h \text{ and } \sigma(\det \lambda(v)) = \det \lambda(v) \}.$$
Lemma 4.2.2 The first equality holds by (4.4). The second equality is an explicit computation: in the division algebra setting, see [15, Equation (2.2)], [1, Lemma 4.4], [5, Section 2.1]; in the present setting of arbitrary inner forms of GL$_n$, see [9, Section 6]. We give an exposition of these works here.

By direct computation, $\mathbb{U}_h \cap F(\mathbb{U}_h^-)$ is the subgroup of $\mathbb{G}_h$ consisting of unipotent lower-triangular matrices whose entries outside the first column vanish:

$$\mathbb{U}_h \cap F(\mathbb{U}_h^-) = \left\{ \begin{pmatrix} \ast & 1 & \cdots & \cdots & \cdots \\ \vdots & \ast & \cdots & \cdots & \cdots \\ \vdots & \vdots & \ast & \cdots & \cdots \\ \vdots & \vdots & \vdots & \ast & \cdots \\ \vdots & \vdots & \vdots & \vdots & \ast \end{pmatrix} \right\}.$$

Suppose that $x \in \mathbb{G}_h$ is such that $x^{-1}F(x) \in \mathbb{U}_h \cap F(\mathbb{U}_h^-)$ and let $x_i$ denote the $i$th column of $x$. Then recalling that $b = t_0^{e_{k,n}} t_{k,n}$ and writing $t_{k,n} = \text{diag}\{t_1, \ldots, t_n\}$, we have

$$F(x) = \begin{pmatrix} b\sigma(x_1) & b\sigma(x_2) & \cdots & b\sigma(x_n) \end{pmatrix} b^{-1} = \begin{pmatrix} t_{1-\varepsilon_{k,n}n}^{-1} b\sigma(x_{1-\varepsilon_{k,n}n}) t_{2-\varepsilon_{k,n}n}^{-1} b\sigma(x_{2-\varepsilon_{k,n}n}) \cdots t_{n-\varepsilon_{k,n}n}^{-1} b\sigma(x_{n-\varepsilon_{k,n}n}) \end{pmatrix}.$$

On the other hand, we have

$$x(\mathbb{U}_h \cap F(\mathbb{U}_h^-)) = \begin{pmatrix} \ast & x_2 & x_3 & \cdots & x_n \end{pmatrix}.$$

Comparing columns, we see that each $x_i$ is uniquely determined by $x_1$ and that we have

$$x_{[(n-1)\varepsilon_{k,n}+1]_n} = t_{[(n-2)\varepsilon_{k,n}+1]_n}^{-1} b\sigma(x_{[(n-2)\varepsilon_{k,n}+1]_n}) \quad (4.7)$$

$$= t_{[(n-2)\varepsilon_{k,n}+1]_n}^{-1} t_{[(n-3)\varepsilon_{k,n}+1]_n}^{-1} b\sigma(x_{[(n-3)\varepsilon_{k,n}+1]_n}) \quad (4.8)$$

$$= t_{[(n-2)\varepsilon_{k,n}+1]_n}^{-1} t_{[(n-3)\varepsilon_{k,n}+1]_n}^{-1} \cdots t_{1}^{-1} b\sigma^{-1}(x_1). \quad (4.9)$$

Using Lemma 4.2.2, we now see that $x = \lambda(x_1)$, and finally, the condition $\sigma(\det \lambda(x)) = \det \lambda(x)$ comes from observation that $x^{-1}F(x)$ must have determinant 1.

Lemma 4.2.2 For $1 \leq i \leq n - 1$,

$$\prod_{j=0}^{i-1} t_{[(j+1)\varepsilon_{k,n}+1]_n} = \omega^{[ik_0/n_0]}.$$

Proof We prove this by induction on $i$. If $i = 1$, then by definition we have $t_1 = 1$, so this proves the base case. Now assume that the lemma holds for $i$. We would like to prove that it holds for $i + 1$. This means we need to prove two assertions:

(a) If $[(i + 1)k_0/n_0] > [ik_0/n_0]$, then $t_{[(i+1)\varepsilon_{k,n}+1]_n} = \omega$. 

(b) If \([ (i + 1)k_0/n_0 ] = [ ik_0/n_0 ]\), then \(t_{[i e_{, n + 1}]} = \sigma\).

The arguments are very similar. For (a): Observe that \([ (i + 1)k_0/n_0 ] > [ ik_0/n_0 ]\) if and only if \(n_0 > [ i e_{, n} ]n_0 > n_0 - k_0 \) since \(e_{, n} \equiv k_0 \mod n_0\). But this happens if and only if \([i e_{, n} + 1]n_0 > n_0 - k_0\), which means \(t_{[i e_{, n + 1}]} = \sigma\) by definition.

For (b): Observe that \([ (i + 1)k_0/n_0 ] = [ ik_0/n_0 ]\) if and only if \([ i e_{, n} ]n_0 = n_0 \) or \([ i e_{, n} ]n_0 < n_0 - k_0\). But this happens if and only if \([ i e_{, n} + 1 ]n_0 \leq n_0 - k_0\), which means that \(t_{[i e_{, n + 1}]} = 1\) by definition.

\[\square\]

### 4.3 The Drinfeld stratification of \(X_h\)

For any divisor \(r \mid n'\), define \(L^{(r)}\) to be the twisted Levi subgroup of \(G\) consisting of matrices \((A_{i, j})_{1 \leq i, j \leq n}\) such that \(A_{i, j} = 0\) unless \(i - j \equiv 0 \mod n_0\). Note that \(L^{(r)} \cong \text{Res}_{k' / k}(\text{GL}_r)\) and that every \(k\)-rational twisted Levi subgroup of \(G\) containing \(T\) is conjugate to \(L^{(r)}\) for some \(r \mid n'\). Let \(\mathbb{L}_h^{(r)}\) denote subgroup of \(\mathbb{G}_h\) associated to \(L^{(r)}\) and define

\[
\mathbb{U}_{h, r} := \mathbb{L}_h^{(r)}\mathbb{U}_{h}^1 \cap \mathbb{U}_h, \quad \mathbb{U}_{h, r}^- := \mathbb{L}_h^{(r)}\mathbb{U}_{h}^{-1} \cap \mathbb{U}_h. 
\]

**Lemma 4.3.1** The isomorphism of \(\mathbb{F}_q\)-schemes (4.4)

\[
(\mathbb{U}_h \cap F\mathbb{U}_h^-) \times (\mathbb{U}_h \cap F^{-1}\mathbb{U}_h) \rightarrow \mathbb{U}_h, \quad (g, x) \mapsto x^{-1}gF(x)
\]

restricts to an isomorphism

\[
(\mathbb{U}_{h, r} \cap F\mathbb{U}_{h, r}^-) \times (\mathbb{U}_{h, r} \cap F^{-1}\mathbb{U}_{h, r}) \rightarrow \mathbb{U}_{h, r}.
\]

**Proof** This lemma is a refinement of [9, Lemma 7.12]. Recall that \(\gamma\mathbb{U}_h\gamma^{-1}\) and \(\gamma\mathbb{U}_h^-\gamma^{-1}\) are the subgroups consisting of unipotent lower- and upper-triangular matrices in \(\mathbb{G}_h\). Recall also that \(F(g) = b_0^{e_{, n}}t_{k, n}\sigma(g)t_{k, n}^{-1}b_0^{e_{, n}}\). Conjugating (4.4), which is proven in op. cit., we have

\[
(\gamma\mathbb{U}_h\gamma^{-1} \cap F_0(\gamma\mathbb{U}_h^-\gamma^{-1})) \times (\gamma\mathbb{U}_h\gamma^{-1} \cap F_0^{-1}(\gamma\mathbb{U}_h\gamma^{-1})) \rightarrow \gamma\mathbb{U}_h\gamma^{-1},
\]

where \(F_0(g) = (b_0\gamma t_{k, n}\gamma^{-1})\sigma(g)(b_0\gamma t_{k, n}\gamma^{-1})^{-1}\). Since \(\gamma L^{(r)}\gamma^{-1} = L^{(r)}\), to prove the lemma, it suffices to show that if \((g, x) \in (\gamma\mathbb{U}_h\gamma^{-1} \cap F_0(\gamma\mathbb{U}_h^-\gamma^{-1})) \times (\gamma\mathbb{U}_h\gamma^{-1} \cap F_0^{-1}(\gamma\mathbb{U}_h\gamma^{-1}))\) is such that \(A = x^{-1}gF(x) \in \gamma\mathbb{U}_h\gamma^{-1}\), then

\[
(g, x) \in (\gamma\mathbb{U}_{h, r}\gamma^{-1} \cap F_0(\gamma\mathbb{U}_{h, r}^-\gamma^{-1})) \times (\gamma\mathbb{U}_{h, r}\gamma^{-1} \cap F_0^{-1}(\gamma\mathbb{U}_{h, r}\gamma^{-1})). \quad (4.10)
\]
Keeping the same notation as in [9, Lemma 7.12], write

\[
x = \begin{pmatrix}
1 & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
b_{21} & 0 & 1 & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
b_{n-1,1} & b_{n-1,2} & \cdots & b_{n-1,n-2} & 1 \\
0 & \cdots & 0 & 0 & 1
\end{pmatrix}, \quad g = \begin{pmatrix}
1 & 0 & 0 & \cdots & 0 \\
c_1 & 1 & 0 & \cdots & 0 \\
b_{31} & 0 & 1 & \cdots & 0 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & 0 & 1
\end{pmatrix}.
\]

Let \( \gamma_{t_k,n} \gamma^{-1} = \text{diag}(s_1, s_2, \ldots, s_n) \) so that we have

\[
F_0(x) = \begin{pmatrix}
1 & 0 & 0 & \cdots & 0 \\
0 & 1 & 0 & \cdots & 0 \\
0 & \sigma(b_{21})s_2/s_1 & 1 & 0 & \cdots \\
0 & \sigma(b_{31})s_3/s_1 & \sigma(b_{32})s_3/s_2 & 1 & \cdots \\
\vdots & \vdots & \vdots & \vdots & \vdots \\
0 & \sigma(b_{n-1,1})s_{n-1}/s_1 & \sigma(b_{n-1,2})s_{n-1}/s_2 & \cdots & \sigma(b_{n-1,n-2})s_{n-1}/s_{n-2} & 1
\end{pmatrix}.
\]

As in [9, Lemma 7.12], we see that the \((i, j)\)th entry of \( gF_0(x) \) is

\[
(gF_0(x))_{i,j} = \begin{cases}
1 & \text{if } i = j, \\
0 & \text{if } i < j, \\
c_{i-1} & \text{if } i > j = 1, \\
\sigma(b_{i-1,j-1})s_{i-1}/s_{j-1} & \text{if } i > j > 1.
\end{cases}
\] (4.11)

We also compute the \((i, j)\)th entry of \( xA \) when \( A = (a_{i,j})_{i,j} \in \gamma \mathbb{U}_h \gamma^{-1} \):

\[
(xA)_{i,j} = \begin{cases}
1 & \text{if } i = j, \\
0 & \text{if } i < j, \\
b_{ij} + \sum_{k=j+1}^{i-1} b_{ik}a_{kj} + a_{ij} & \text{if } j < i \leq n - 1, \\
a_{nj} & \text{if } j < i = n.
\end{cases}
\] (4.12)

We now have \( n^2 \) equations given by (4.11) = (4.12), viewed as equations in the variables \( b_{i,j} \) and \( c_i \). Let \( \overline{b}_{i,j}, \overline{c}_i, \overline{a}_{i,j} \) denote the images of \( b_{i,j}, c_i, a_{i,j} \) in \( \mathbb{W}_1 \). In particular, we have the following:

\[
\overline{b}_{n-1,j-1} = 0 \iff \overline{a}_{n,j} = 0, \quad (4.13)
\]

and for \( 1 < j < i < n \),

\[
\overline{b}_{i-1,j-1} = 0 \iff \overline{b}_{i,j} + \sum_{k=j+1}^{i-1} \overline{b}_{i,k} \overline{a}_{k,j} + \overline{a}_{i,j} = 0. \quad (4.14)
\]
Assume now that \( A \in \gamma \mathbb{U}_{h,r} \gamma^{-1} = \gamma (\mathbb{L}^{(r)}_h \mathbb{U}^1_h \cap \mathbb{U}_h) \gamma^{-1} \). Then \( \mathfrak{a}_{i,j} = 0 \) if \( r n_0 \nmid i - j \). From (4.13) we see that \( \mathfrak{b}_{n-1,j-1} = 0 \) if \( r n_0 \nmid n - j = (n - 1) - (j - 1) \). We now proceed by (decreasing) induction on \( i \). If \( i, j \) are such that \( 1 < j < i < n \) and \( r n_0 \nmid i - j \), then necessarily either \( r n_0 \nmid i - k \) or \( r n_0 \nmid k - j \), and therefore each term in the sum on the right-hand side of (4.14) is zero, and so \( \mathfrak{b}_{i-1,j-1} = 0 \).

We have therefore shown that \( x \in \gamma (\mathbb{L}^{(r)}_h \mathbb{U}^1_h \cap \mathbb{U}_h) \gamma^{-1} \cap F^{-1} (\gamma \mathbb{U}_h \gamma^{-1}) \). In particular, \( F(x) \in \gamma \mathbb{U}_h \gamma^{-1} \). Since \( \mathbb{L}^{(r)}_h \) is \( F \)-stable, we have that \( F(\mathfrak{X}) \in \mathbb{L}^{(r)}_1 \) and therefore \( F(x) \in \gamma (\mathbb{U}_h \cap \mathbb{L}^{(r)}_h \mathbb{U}^1_h) \gamma^{-1} \). Hence \( x \in \gamma (\mathbb{U}_{h,r} \cap F^{-1} \mathbb{U}_{h,r}) \gamma^{-1} \).

Now since \( \mathfrak{A}, \mathfrak{X} \in \mathbb{L}^{(r)}_1 \), we must have \( \mathfrak{g} \in \mathbb{L}^{(r)}_1 \). Since \( g \in \gamma \mathbb{U}_h \gamma^{-1} \), we must have \( g \in \gamma (\mathbb{L}^{(r)}_h \mathbb{U}^1_h \cap \mathbb{U}_h) \gamma^{-1} = \gamma \mathbb{U}_h \gamma^{-1} \), and since \( g \in F(\gamma \mathbb{U}_h \gamma^{-1}) \), we must have \( g \in F(\gamma (\mathbb{L}^{(r)}_h \mathbb{U}^1_h \cap \mathbb{U}_h) \gamma^{-1}) \). Hence \( g \in \gamma \mathbb{U}_{h,r} \gamma^{-1} \cap F(\gamma \mathbb{U}_{r} \gamma^{-1}) \). This establishes (4.10) and finishes the proof of the lemma.

\[ \textbf{Definition 4.3.2} \quad \text{(Drinfeld stratification for } X_h) \quad \text{For each divisor } r \mid n', \text{ we define} \]

\[
S_h^{(r)} := \{ x \in \mathbb{G}_h : x^{-1} F(x) \in \mathbb{U}_{h,r} \}, \\
X_h^{(r)} := \{ x \in \mathbb{G}_h : x^{-1} F(x) \in \mathbb{U}_{h,r} \}/(\mathbb{U}_{h,r} \cap F^{-1} \mathbb{U}_{h,r}) \\
= \{ x \in \mathbb{G}_h : x^{-1} F(x) \in \mathbb{U}_{h,r} \} \cap F \mathbb{U}_{r}^{-1},
\]

where the second equality in \( X_h^{(r)} \) holds by Lemma 3.3.

Note that \( S_h^{(r)} \) is the variety \( S_h^{(L)} \) defined in Sect. 3.3 in the special case that \( G \) is an inner form of \( \text{GL}_n \), the twisted Levi \( L \) is \( L^{(r)} \), and \( U \) is the unipotent radical of the Borel subgroup specified in Sect. 4.2. By Lemma 4.3.1, we can change the quotient in the definition of \( X_h^{(r)} \) from \( \mathbb{U}_{h,r} \cap F^{-1} \mathbb{U}_{h,r} \) to \( \mathbb{U}_{h} \cap F^{-1} \mathbb{U}_{h} \) so that \( X_h^{(r)} \) is the image of \( S_h^{(r)} \) in \( X_h \); that is, \( X_h^{(r)} \) as defined in Definition 4.3.2 agrees with the variety \( X_h^{(L)} \) defined in 3.3.2 in the special case \( L = L^{(r)} \). Hence we have the picture:

\[
\begin{array}{ccc}
S_h^{(r)} & \longrightarrow & S_h \\
\downarrow & & \downarrow \\
X_h^{(r)} & \longrightarrow & X_h
\end{array}
\]

### 4.4 The Drinfeld stratification for the Drinfeld upper half-space

Consider the twisted Frobenius \( b_{\text{cox}} \sigma : \bar{k}^{\oplus n} \to \bar{k}^{\oplus n} \). Then \( G(k) = J_{b_{\text{cox}}} (k) \) is equal to the subgroup consisting of all elements of \( \text{GL}_n (\bar{k}) \) which commute with \( b_{\text{cox}} \sigma \). Now consider the subquotient of \( \bar{k}^{\oplus n} \) given by

\[
\mathcal{L}_h := (\mathbb{W}_h (\bar{F}_q) \oplus (V \mathbb{W}_{h-1} (\bar{F}_q)^{\oplus n_0 - 1}))^{\oplus n'} \subset \mathbb{W}_h (\bar{F}_q)^{\oplus n}
\]
and write \( \mathcal{L} = \lim_{\leftarrow} h \mathcal{L}_h \). The action of \( G(k) \) on \( \tilde{k}^\otimes n \) restricts to an action of \( G_{x,0}(\mathcal{O}_k) \) on \( \mathcal{L} \) which induces an action of \( \mathcal{G}_h(\mathbb{F}_q) \) on \( \mathcal{L}_h \).

Now consider the \( n' \)-dimensional \( \mathbb{F}_q \)-vector space \( V := \mathcal{L}_1 \subset \mathbb{F}_q^\otimes n \). The morphism \( \sigma^{-k_0}(b_{\text{cox}}\sigma)^{n_0} \) is a Frobenius automorphism of \( V \) and defines a \( \mathbb{F}_{q^{n_0}} \)-rational structure on \( V \). Observe that \( \mathcal{G}_1(\mathbb{F}_q) \) is isomorphic to the subgroup of \( \text{GL}(V) \) consisting of elements which commute with \( \sigma^{-k_0}(b_{\text{cox}}\sigma)^{n_0} \). For any divisor \( r \mid n' \) and any \( \mathbb{F}_{q^{n_0r}} \)-rational subspace \( W \) of \( V \), consider

\[
\Omega_{W,q^{n_0r}} := \{ [x] \in \mathbb{P}(V) : W \text{ is the smallest } \mathbb{F}_{q^{n_0r}} \text{-rational subspace of } V \text{ containing } x \}.
\]

Note that \( \Omega_{W,q^{n_0r}} \subset \mathbb{P}(V) \) is isomorphic to the Drinfeld upper half-space for \( W \) with respect to \( \mathbb{F}_{q^{n_0r}} \). For any divisor \( r \mid n' \), define

\[
\mathcal{I}_r := \bigcup_W \Omega_{W,q^{n_0r}},
\]

where the union ranges over all \( \mathbb{F}_{q^{n_0r}} \)-rational subspaces \( W \) of dimension \( n'/r \) in \( V \). The following lemma records some easy facts.

**Lemma 4.4.1** We have

(i) \( \mathcal{I}_1 = \Omega_{V,q^{n_0}} \) and \( \mathcal{I}_{n'} = \mathbb{P}(V)(\mathbb{F}_q^n) \).

(ii) If \( r \mid r' \mid n' \) and \( W \) is a \( \mathbb{F}_{q^{n_0r}} \)-rational subspace of \( V \), then \( \Omega_{W,q^{n_0r'}} \subset \Omega_{W,q^{n_0r}} \).

(iii) If \( r \mid r' \mid n' \), then \( \mathcal{I}_1 \cap \mathcal{I}_{r'} \subset \mathcal{I}_1 \cap \mathcal{I}_r \).

Note that \( \mathcal{I}_1 \) is the classical Deligne–Lusztig variety for \( \mathcal{G}_1(\mathbb{F}_q) \cong \text{GL}_{n'}(\mathbb{F}_{q^{n_0}}) \) with respect to the nonsplit maximal torus \( T_1(\mathbb{F}_q) \cong \mathbb{F}_q^\times \) [11, Section 2.2] and the variety \( X_h \) when \( h = 1 \) is a \( \mathbb{F}_{q^n} \)-cover of \( \mathcal{I}_1 \). Hence for any \( h \geq 1 \), we have a map

\[
X_h \rightarrow X_1 \rightarrow \mathcal{I}_1.
\]

**Lemma 4.4.2** For any divisor \( r \mid n' \), the variety \( X_h^{(r)} \) is the preimage of \( \mathcal{I}_1 \cap \mathcal{I}_r \) under the composition map \( X_h \rightarrow X_1 \rightarrow \mathcal{I}_1 \).

**Proof** To prove this, we use the explicit description of \( X_h \) coming from Lemma 4.2.1:

\[
X_h = \{ \lambda(v) \in \mathcal{G}_h : v \in \mathcal{L}_h \text{ and } \sigma(\det \lambda(v)) = \det \lambda(v) \}.
\]

By Definition 4.3.2, if \( v \in \mathcal{L}_h \) is such that \( \lambda(v) \in X_h^{(r)} \), then \( \lambda(v)^{-1}F(\lambda(v)) \in \mathbb{U}_{h,r} \cap F\mathbb{U}_{h,r}^- \), which is equivalent to

\[
F(\lambda(v)) = \lambda(v)A, \quad \text{for some } A \in \mathbb{U}_{h,r} \cap F\mathbb{U}_{h,r}^-.
\]
Note that $A = (a_{i,j})_{1 \leq i, j \leq n}$ has the property that

\[
\begin{align*}
a_{i,i} &= 1, & \text{for } i = 1, \ldots, n, \\
a_{i,1} &\in \mathbb{W}_h, & \text{if } i \equiv 1 \mod rn_0, \\
a_{i,1} &\in V\mathbb{W}_{h-1} \subset \mathbb{W}_h, & \text{if } i \not\equiv 1 \mod rn_0, \\
a_{i,j} &= 0 \text{ otherwise.}
\end{align*}
\]

The first column of $F(\lambda(v))$ is the vector $\sigma^n(v)$. Therefore (4.4) implies that

\[
\sigma^n(v) = \sum_{i=1}^{n} a_{i,1} \lambda(v)_i = v + \sum_{i=2}^{n} a_{i,1} \lambda(v)_i,
\]

where $\lambda(v)_i$ denotes the $i$th column of $\lambda(v)$. Recall from (4.6) that $\lambda(v)_{[ie_{\kappa,n}+1]} = \prod_{j=0}^{i-1} t_{[ie_{\kappa,n}+1]}^{-1} \cdot (b\sigma)^j(v)$. If $[ie_{\kappa,n}+1] \equiv 1 \mod rn_0$, then $i \equiv 0 \mod rn_0$. Therefore, if $v$ denotes the image of $v$ in $\mathcal{L}_1$, we have (using (4.6)),

\[
\sigma^n(v) \in \text{span}\{v, \sigma^{-r_{k_0}}(b\sigma)^{r_{n_0}}(v), \sigma^{-2r_{k_0}}(b\sigma)^{2r_{n_0}}(v), \ldots, \sigma^{-(n'-1)r_{k_0}}(b\sigma)^{(n'-1)r_{n_0}}(v)\}.
\]

Since $\lambda(v) \in \mathbb{G}_h$, necessarily $v, \sigma^{-r_{k_0}}(b\sigma)^{r_{n_0}}(v), \ldots, \sigma^{-(n'-1)r_{k_0}}(b\sigma)^{(n'-1)r_{n_0}}(v)$ are linearly independent and therefore span a $n'/r$-dimensional subspace of $\mathcal{L}_1$. This exactly means that $v \in \mathcal{I}_1 \cap \mathcal{J}_r$, so the proof is complete.

**Remark 4.4.3** By Lemma 4.4.2, we see that for $\text{GL}_n$ and its inner forms, the Drinfeld stratification of $X_h$ is induced by considering intermediate Drinfeld upper half-spaces of smaller dimension embedding in $\mathbb{P}^{n'-1}_{\mathbb{F}_{q^{n_0}}}$.

### 4.5 The Drinfeld stratification of $X_h(b, w)$

In this section, we consider the varieties $X_h(b, w)$ in the special case

\[
b = g_0 b_{\text{cox}} \sigma(g_0)^{-1} \text{ for some } g_0 \in G_{x,0}(\mathcal{O}_k), \quad \text{and} \quad w = b_{\text{cox}}.
\]

For any such $b$, recall from Lemmas 3.2.2 and 3.2.3 that

\[
X_h = X_h(b_{\text{cox}}, b_{\text{cox}}) \cong X_h(b, b_{\text{cox}}), \quad (4.15)
\]

where the second isomorphism is given by $x \mapsto \overline{g_0}x$, where $\overline{g_0}$ is the image of $g_0$ in $\mathbb{G}_h(\overline{\mathbb{F}_q})$. Therefore the Drinfeld stratification $\{X_h^{(r)}\}$ of $X_h$ gives rise to a stratification $\{X_h^{(r)}(b, b_{\text{cox}})\}$ for $X_h(b, b_{\text{cox}})$. The proof of Lemma 4.5.3 shows that if $\sigma^n(\overline{g_0}) = \overline{g_0}$, then the Drinfeld stratification of $X_h(b, b_{\text{cox}})$ does not depend on the choice of $g_0$. 
Lemma 4.5.1 Let $b = g_0 b_{\text{cox}} \sigma(g_0)^{-1} \in G(\tilde{k})$ for some $g_0 \in G_{x,0}(O_{\tilde{k}})$. To each $v \in \mathcal{L}_h$, define

$$g_b(v) := \begin{pmatrix} v_1 & v_2 & v_3 & \cdots & v_n \end{pmatrix}$$

where $v_i := \sigma^{{\ell(i-1)k_0/n_0}} \cdot (b\sigma)^{-1}(v)$ for $1 \leq i \leq n - 1$,

where we abuse notation by writing $\sigma^{{\ell(i-1)k_0/n_0}} \cdot (b\sigma)^{-1}$ for the map $\mathcal{L}_h \to \mathcal{L}_h$ which takes $v$ to the image $\sigma^{{\ell(i-1)k_0/n_0}} \cdot (b\sigma)^{-1}(v)$ in the subquotient $\mathcal{L}_h$ of $\tilde{k}^\oplus n$, where $\tilde{v}$ is any lift of $v$ in $\mathcal{L} \subset \tilde{k}^\oplus n$.

Lemma 4.5.2 If $b = g_0 b_{\text{cox}} \sigma(g_0)^{-1}$ for some $g_0 \in G_{x,0}(O_{\tilde{k}})$, then

$$X_h(b, b_{\text{cox}}) \cong \{ v \in \mathcal{L}_h : \sigma(\det g_b(v)) = \frac{\det b_{\text{cox}}}{\det b} \cdot \det g_b(v) \in \mathbb{W}_h^\times \}.$$  

Proof. First note that one can obtain $g_b(v)$ from $\lambda(v)$ by permuting columns. In particular,

$$X_h(b_{\text{cox}}, b_{\text{cox}}) = X_h \cong \{ v \in \mathcal{L}_h : \sigma(\det g_{b_{\text{cox}}}(v)) = \det g_{b_{\text{cox}}}(v) \in \mathbb{W}_h^\times \}.$$  

Since $X_h(b_{\text{cox}}, b_{\text{cox}}) \cong X_h(b, b_{\text{cox}})$ is given by $x \mapsto \overline{g}_0 x$ where $\overline{g}_0$ denotes the image of $g_0$ in $G_h(\overline{F}_q)$, we have that $X_h(b, b_{\text{cox}})$ is isomorphic to the set of $\overline{g}_0 \cdot g_{b_{\text{cox}}}(v)$ where $v \in \mathcal{L}_h$ satisfies the above criterion. By direct computation,

$$\overline{g}_0 \cdot g_{b_{\text{cox}}}(v) = g_b(\overline{g}_0 \cdot v),$$

and hence if $\sigma(\det g_{b_{\text{cox}}}(v)) = \det g_{b_{\text{cox}}}(v)$, then

$$\sigma(\det g_b(\overline{g}_0 \cdot v)) = \sigma(\det \overline{g}_0) \cdot \sigma(\det g_{b_{\text{cox}}}(v)) = \sigma(\det \overline{g}_0) \cdot \det g_{b_{\text{cox}}}(v) = \frac{\det b_{\text{cox}}}{\det \overline{g}_0} \cdot \det g_b(\overline{g}_0 \cdot v) = \frac{\det b_{\text{cox}}}{\det b} \cdot \det g_b(\overline{g}_0 \cdot v).$$

Lemma 4.5.3 Let $b = g_0 b_{\text{cox}} \sigma(g_0)^{-1}$ for some $g_0 \in G_{x,0}(O_{\tilde{k}})$ and assume that the image $\overline{g}_0 \in G_h(\overline{F}_q)$ of $g_0$ has the property that $\sigma^n(\overline{g}_0) = \overline{g}_0$. Let $r \mid n'$ be any divisor. For $v \in \mathcal{L}_h$, let $v$ denote its image in $\mathcal{L}_1$. Then

$$X_h(b, b_{\text{cox}})^{(r)} \cong \left\{ v \in \mathcal{L}_h : \sigma(\det g_{b_{\text{cox}}}(v)) = \frac{\det b_{\text{cox}}}{\det b} \cdot \det g_b(v) \in \mathbb{W}_h^\times \right\}.$$  

In particular, the Drinfeld stratification of $X_h(b, b_{\text{cox}})$ does not depend on the choice of $g_0$. 

**Proof** Recall that

\[
X_h(b_{\text{cox}}, b_{\text{cox}}) = \left\{ v \in \mathcal{L}_h : \sigma(\det g_{b_{\text{cox}}}(v)) = \det g_{b_{\text{cox}}}(v) \in \mathbb{W}_h^\times \right\}.
\]

By definition, every element in \( X_h(b_{\text{cox}}, b_{\text{cox}}) \) is of the form \( g_0 g_{b_{\text{cox}}}(v) \) for some \( v \in \mathcal{L}_h \) satisfying the above criteria. Since \( g_0 g_{b_{\text{cox}}}(v) = g_b(\overline{g_0} v) \) and since \( \sigma(g_0) = g_0 \), we have \( g_0 \sigma^n(v) \in \text{span}\{ \overline{g_0} \sigma^{-ik_0} (b_{\text{cox}} \sigma)^{irn_0}(v) : 0 \leq i \leq n' - 1 \} \).

But now \( \overline{g_0} \sigma^{-ik_0} (b_{\text{cox}} \sigma)^{irn_0}(v) = \overline{\sigma}^{-ik_0} (b \sigma)^{irn_0}(v) \) and therefore the desired conclusion follows.

**Remark 4.5.4** In “Appendix A”, we will work directly with a particular \( b \) called the special representative in [9] (see Definition A.1.1 of the present paper). The special representative satisfies the hypotheses of Lemma 4.5.3.

## 5 Torus eigenspaces in the cohomology

We prove an irreducibility result for torus eigenspaces in the alternating sum of the cohomology of \( X_h \cap \mathbb{L}_h G_1^h \).

### 5.1 Howe factorizations

Let \( \mathcal{T}_{n,h} \) denote the set of characters \( \theta : \mathbb{W}_h^\times(\mathbb{F}_{q^n}) \to \mathbb{Q}_\ell^\times \). Recall that if \( h \geq 2 \), we have natural surjections \( \text{pr} : \mathbb{W}_h^\times \to \mathbb{W}_{h-1}^\times \) and injections \( \mathbb{G}_a \to \mathbb{W}_h^\times \) given by \( x \mapsto [1, 0, \ldots, 0, x] \). For every divisor \( m \) of \( n \), we have norm maps \( \text{Nm} : \mathbb{W}_h^\times(\mathbb{F}_{q^n}) \to \mathbb{W}_h^\times(\mathbb{F}_{q^m}) \). These maps induce

\[
\text{pr}^* : \mathcal{T}_{n,h'} \to \mathcal{T}_{n,h}, \quad \text{for } h' < h,
\]

\[
\text{Nm}^* : \mathcal{T}_{m,h} \to \mathcal{T}_{n,h}, \quad \text{for } m \mid n.
\]

First consider the setting \( h \geq 2 \). By pulling back along \( \mathbb{G}_a \to \mathbb{W}_h^\times, x \mapsto [1, 0, \ldots, 0, x] \), we may restrict characters of \( \mathbb{W}_h^\times(\mathbb{F}_{q^n}) \) to characters of \( \mathbb{F}_{q^n} \). We say that \( \theta \in \mathcal{T}_{n,h} \) is primitive if \( \theta|_{\mathbb{F}_{q^n}} \) has trivial stabilizer in \( \text{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q) \). If \( h = 1 \), then \( \theta \in \mathcal{T}_{n,h} \) is a character \( \theta : \mathbb{F}_{q^n}^\times \to \mathbb{Q}_\ell^\times \), and we say it is primitive if \( \theta \) has trivial stabilizer in \( \text{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q) \). For any \( h \geq 1 \), we write \( \mathcal{T}_{n,h}^0 \subset \mathcal{T}_{n,h} \) to denote the subset of primitive characters.

We can decompose \( \theta \in \mathcal{T}_{n,h} \) into primitive components in the sense of Howe [13, Corollary after Lemma 11].
Definition 5.1.1 A *Howe factorization* of a character $\theta \in \mathcal{T}_{n,h}$ is a decomposition

$$\theta = \prod_{i=1}^{d} \theta_i,$$

where $\theta_i = \text{pr}^* Nm^* \theta_i^0$ and $\theta_i^0 \in \mathcal{T}_{m_i, h_i}$,

such that $m_i < m_{i+1}$, $m_i \mid m_{i+1}$, and $h_i > h_{i+1}$. It is automatic that $m_i \leq n$ and $h \geq h_i$. For any integer $0 \leq t \leq d$, set $\theta_t$ to be the trivial character and define

$$\theta_{\geq t} := \prod_{i=t}^{d} \theta_i \in \mathcal{T}_{n, h_i}.$$ 

Observe that the choice of $\theta_i$ in a Howe factorization $\theta = \prod_{i=1}^{d} \theta_i$ is not unique, but the $m_i$ and $h_i$ only depend on $\theta$. Hence the Howe factorization attaches to each character $\theta \in \mathcal{T}_{n, h}$ a pair of well-defined sequences

$$1 =: m_0 \leq m_1 < m_2 < \cdots < m_d \leq m_{d+1} := n$$
$$h =: h_0 \geq h_1 > h_2 > \cdots > h_d \geq h_{d+1} := 1$$

satisfying the divisibility $m_i \mid m_{i+1}$ for $0 \leq i \leq d$.

Example 5.1.2 We give some examples of the sequences associated to characters $\theta \in \mathcal{T}_{n, h}$.

(a) If $\theta$ is the trivial character, then $d = 1$ and the associated sequences are

$$\{m_0, m_1, m_2\} = \{1, 1, n\}, \quad \{h_0, h_1, h_2\} = \{h, 1, 1\},$$

where we note that $\mathcal{T}_{1,1} = \mathcal{T}_{1,1}^0$ since any character of $\mathbb{F}_q^\times$ has trivial $\text{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q)$-stabilizer.

(b) Say $h \geq h'$. We say that $\theta$ is a primitive character of level $h' \geq 2$ if $\theta|_{\mathbb{F}_{q^{h'}}^\times} = 1$ and $\theta|_{\mathbb{F}_{q^{h'-1}}^\times}$ has trivial $\text{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q)$-stabilizer. Then $d = 1$ and the associated sequences are

$$\{m_0, m_1, m_2\} = \{1, n, n\}, \quad \{h_0, h_1, h_2\} = \{h, h', 1\}.$$

In the division algebra setting, this case is studied in [3,4]. For arbitrary inner forms of GL$_n$ over $K$, we considered *minimal admissible* $\theta$, which are exactly the characters $\theta \in \mathcal{T}_{n, h}$ which are either primitive or have $d = 2$ with associated sequences

$$\{m_0, m_1, m_2, m_3\} = \{1, 1, n, n\}, \quad \{h_0, h_1, h_2, h_3\} = \{h, h_1, h_2, 1\}.$$

This is a very slight generalization over the primitive case.
(c) Say \( h \geq 2 \). If \( \theta|_{W_{\Sigma}^h(F_q^n)} = 1 \) and the stabilizer of \( \theta|_{W_{\Sigma}^h(F_q^n)} \) in \( \text{Gal}(\mathbb{F}_q^n/\mathbb{F}_q) \) is \( \text{Gal}(\mathbb{F}_q^n/\mathbb{F}_q^n) \), then \( d = 1 \) and the associated sequences are

\[
\{m_0, m_1, m_2\} = \{1, m, n\}, \quad \{h_0, h_1, h_2\} = \{h, 2, 1\}.
\]

In the division algebra setting, the case \( h = 2 \) is studied in [1,2].

(d) Say \( h \geq 1 \). If \( \theta|_{W_{\Sigma}^h(F_q^n)} = 1 \) and the stabilizer of \( \theta : \mathbb{F}_q^n \to \overline{\mathbb{Q}}_\ell^\times \) is \( \text{Gal}(\mathbb{F}_q^n/\mathbb{F}_q^n) \), then \( d = 1 \) and the associated sequences are

\[
\{m_0, m_1, m_2\} = \{1, m, n\}, \quad \{h_0, h_1, h_2\} = \{h, 1, 1\}.
\]

This is the so-called “depth zero” case.

### 5.2 Irreducibility

Recall that the intersection \( X_h \cap \mathbb{L}_h^{(r)} \mathbb{G}_h^1 \) has an action by the subgroup \( L_h^{(r)}(\mathbb{F}_q) \mathbb{G}_h^1(\mathbb{F}_q) \times T_h(\mathbb{F}_q) \subset \mathbb{G}_h(\mathbb{F}_q) \times T_h(\mathbb{F}_q) \). In this section, we study the irreducibility of the virtual \( L_h^{(r)}(\mathbb{F}_q) \mathbb{G}_h^1(\mathbb{F}_q) \)-representation \( H^*_c(X_h \cap \mathbb{L}_h^{(r)} \mathbb{G}_h^1)[\theta] \), where \( \theta : T_h(\mathbb{F}_q) \to \overline{\mathbb{Q}}_\ell^\times \) is arbitrary.

We follow a technique of Lusztig which has appeared in the literature in many incarnations, the closest analogues being [7,16,18]. In these works, the strategy is to translate the problem of calculating an inner product between two representations to calculating the cohomology of a third variety \( \Sigma \). This is done by first writing \( \Sigma = \Sigma' \cup \Sigma'' \), proving the cohomology of \( \Sigma'' \) gives the expected outcome, and then putting a lot of work into showing that the cohomology of \( \Sigma' \) does not contribute. In the three works cited, one can only prove the vanishing of (certain eigenspaces of the) Euler characteristic of \( \Sigma' \) under a strong regularity condition on the characters \( \theta, \theta' \).

The key new idea here is adapted from [8, Section 3.2], which allows us to relax this regularity assumption by working directly with \( \Sigma \) throughout the proof. We give only a sketch of the proof of Theorem 5.2.1 here, as the proof of [8, Theorem 3.1] is very similar.

**Theorem 5.2.1** Let \( \theta, \theta' : T_h(\mathbb{F}_q) \to \overline{\mathbb{Q}}_\ell^\times \) be any two characters. Then

\[
\left\{ H^*_c(X_h \cap \mathbb{L}_h^{(r)} \mathbb{G}_h^1)[\theta], H^*_c(X_h \cap \mathbb{L}_h^{(r)} \mathbb{G}_h^1)[\theta'] \right\}_{L_h^{(r)}(\mathbb{F}_q) \mathbb{G}_h^1(\mathbb{F}_q)} = \# \{ w \in W^F_{L_h^{(r)}} : \theta' = \theta \circ \text{Ad}(w) \},
\]

where \( W^F_{L_h^{(r)}} = N_{L_h^{(r)}(\mathbb{F}_q)}(T_h(\mathbb{F}_q))/T_h(\mathbb{F}_q) \).

Since \( W^F_{L_h^{(r)}} \cong \text{Gal}(\mathbb{F}_q^n/\mathbb{F}_q^{q^a}) \), we obtain the following theorem as a direct corollary of Theorem 5.2.1.

**Corollary 5.2.2** Let \( \theta : T_h(\mathbb{F}_q) \cong \mathbb{W}_h^\times(\mathbb{F}_q^n) \to \overline{\mathbb{Q}}_\ell^\times \) be any character. Then the virtual \( L_h^{(r)}(\mathbb{F}_q) \mathbb{G}_h^1(\mathbb{F}_q) \)-representation \( H^*_c(X_h \cap \mathbb{L}_h^{(r)} \mathbb{G}_h^1)[\theta] \) is (up to sign) irreducible if and only if \( \theta \) has trivial \( \text{Gal}(\mathbb{F}_q^n/\mathbb{F}_q^{q^a}) \)-stabilizer.
In the special case that \( r = n' \), we have \( \mathbb{L}_h^{(r')} = T_h \) and using Lemma 4.2.1 and Definition 4.3.2, we have that \( S_h \cap T_h G_h^1 \) is an affine fibration over

\[ \left\{ x \in T_h G_h^1 : x^{-1} F(x) \in U_h^1 \cap F U_h^{-1} \right\}. \]

and that

\[ X_h \cap T_h G_h^1 = \bigcup_{t \in T_h(F_q)} t \cdot X_h^1, \quad \text{where} \quad X_h^1 = X_h \cap G_h^1. \]

Here we have

\[ X_h^1 = \{ x \in G_h^1 : x^{-1} F(x) \in U_h^1 \cap F U_h^{-1} \}. \quad (5.1) \]

**Corollary 5.2.3** Let \( \chi : T_h(F_q) \to \overline{\Omega}_\ell^X \) be any character. Then \( H^*_c(X_h^1, \overline{\Omega}_\ell)[\chi] \) is an irreducible representation of \( G_h^1(F_q) \). Moreover, if \( \chi, \chi' \) are any two characters of \( T_h(F_q) \), then \( H^*_c(X_h^1, \overline{\Omega}_\ell)[\chi] \cong H^*_c(X_h^1, \overline{\Omega}_\ell)[\chi'] \) if and only if \( \chi = \chi' \).

Corollary 5.2.3 follows from Corollary 5.2.2 (by arguing the relationship between the cohomology of \( X_h^1 \) and the cohomology of \( X_h \cap T_h G_h^1 \)), but one can give an alternate proof using [5, Section 6.1], which is based on [15]. We do this in Sect. 5.2.2.

**Remark 5.2.4** Recall that specializing Lemma 3.3.4 yields that

\[ H^*_c(X_h^1, \overline{\Omega}_\ell)[\theta] \cong \text{Ind}_{\mathbb{L}_h^{(r')}(F_q)}^{G_h^1(F_q)} \left( H^*_c(X_h \cap \mathbb{L}_h^{(r)} G_h^1, \overline{\Omega}_\ell)[\theta] \right). \]

We expect that \( H^*_c(X_h^1, \overline{\Omega}_\ell)[\theta] \) should be irreducible if \( \theta \) satisfies an appropriate regularity condition depending on \( r \). In the case \( r = n' \), we prove in [8, Theorem 4.1(b)] that \( H^*_c(X_h^1, \overline{\Omega}_\ell)[\theta] \) is irreducible if \( \theta|_{T_h(F_q)} \) has trivial Gal\((F_{q^n}/F_q)\)-stabilizer. (This is more subtle than one might expect—as an indication of this subtlety, we remark that we are only able to establish this irreducibility for \( p > n \).)

5.2.1 Proof of Theorem 5.2.1

Recall that by definition

\[ S_h \cap \mathbb{L}_h^{(r)} G_h^1 = \{ g \in \mathbb{L}_h^{(r)} G_h^1 : g^{-1} F(g) \in U_{h,r} \}, \quad \text{where} \quad U_{h,r} = \mathbb{L}_h^{(r)} U_h^1 \cap U_h. \]

Consider the variety

\[ \Sigma^{(r)} = \left\{ (x, x', y) \in F(U_{h,r}) \times F(U_{h,r}) \times \mathbb{L}_h^{(r)} G_h^1 : x F(y) = y x' \right\} \]

endowed with the \( T_h(F_q) \times T_h(F_q) \)-action given by \( (t, t') : (x, x', y) \mapsto (t x t^{-1}, t' x' t'^{-1}, t y t^{-1}) \). Then we have an isomorphism

\[ \mathbb{L}_h^{(r)}(F_q) G_h^1(F_q) \setminus \left( (S_h \cap \mathbb{L}_h^{(r)} G_h^1) \times (S_h \cap \mathbb{L}_h^{(r)} G_h^1) \right) \to \Sigma^{(r)}, \]

\[ (g, g') \mapsto (g^{-1} F(g), g'^{-1} F(g'), g^{-1} g'). \]
equivariant with respect to $\mathbb{T}_h(\mathbb{F}_q) \times \mathbb{T}_h(\mathbb{F}_q)$. To prove Theorem 5.2.1, we need to establish

$$\sum_i (-1)^i \dim H^i_c(\Sigma^{(r)}, \bar{\Sigma}_\ell \theta, \theta') = \# \left\{ w \in W^{F}_{\bar{\Sigma}_\ell} : \theta' = \theta \circ \text{Ad}(w) \right\}. \quad (5.2)$$

The Bruhat decomposition of the reductive quotient $G_1$ lifts to a decomposition $G_h = \bigsqcup_{w \in W_{G_h}} G_{h,w}$, where $G_{h,w} = U_h T_h \mathbb{L}_h^1 \mathbb{U}_h$ and $\mathbb{K}_h^1 = (\mathbb{U}_h^{-1})^1 \cap \mathbb{U}_h^{-1} \mathbb{U}_h^{-1} w$ [7, Lemma 8.6]. This induces the decomposition

$$\mathbb{L}_h^{(r)} G_h^1 = \bigsqcup_{w \in W_{\mathbb{L}_h^{(r)}}} G_{h,w}^{(r)}, \quad \text{where } G_{h,w}^{(r)} = G_{h,w} \cap \mathbb{L}_h^{(r)} G_h^1,$$

and also the locally closed decomposition

$$\Sigma^{(r)} = \bigsqcup_{w \in W_{\mathbb{O}}} \Sigma_w^{(r)}, \quad \text{where } \Sigma_w^{(r)} = \Sigma \cap (F(\mathbb{U}_{h,r}) \times F(\mathbb{U}_{h,r}) \times G_{h,w}^{(r)}) .$$

We will calculate (5.2) by analyzing the cohomology of

$$\hat{\Sigma}_w^{(r)} = \{(x, x', y_1, \tau, z, y_2) \in F(\mathbb{U}_{h,r}) \times F(\mathbb{U}_{h,r}) \times \mathbb{U}_{h,r} \times T_h \times \mathbb{K}_h^1 \times \mathbb{U}_h : x F(y_1 \tau w z y_2) = y_1 \tau w z y_2 x' \}.$$

Since $\hat{\Sigma}_w^{(r)} \to \Sigma_w^{(r)}, (x, x', y_1, \tau, z, y_2) \mapsto (x, x', y_1 \tau z y_2)$ is a locally trivial fibration, showing (5.2) is equivalent to showing

$$\sum_i (-1)^i \dim H^i_c(\hat{\Sigma}_w^{(r)}, \bar{\Sigma}_\ell \theta, \theta') = \begin{cases} 1 & \text{if } w \in W^{F}_{\bar{\Sigma}_\ell} \text{ and } \theta' = \theta \circ \text{Ad}(w), \\ 0 & \text{otherwise}. \end{cases} \quad (5.3)$$

As in [16, 1.9], we can simplify the formulation of $\hat{\Sigma}_w$ by replacing $x$ by $x F(y_1)$ and replacing $x'$ by $x' F(y_2)^{-1}$. We then obtain

$$\hat{\Sigma}_w^{(r)} = \{(x, y_1, \tau, z, y_2) \in F\mathbb{U}_{h,r} \times \mathbb{U}_{h,r} \times T_h \times \mathbb{K}_h^1 \times \mathbb{U}_{h,r} : x F(\tau w z) \in y_1 \tau w z y_2 F\mathbb{U}_{h,r} \}.$$

Lemma 5.2.5 Assume that there exists some $2 \leq i \leq n$ which satisfies the string of inequalities $[\gamma w \gamma^{-1}(i)] > [\gamma w \gamma^{-1}(i-1) + 1] > 1$. Then $\hat{\Sigma}_w = \emptyset$.

Proof By the same argument as in [8, Lemma 3.4], we may assume $h = 1$ and come to the statement that $\hat{\Sigma}_w = \emptyset$ if there does not exist $(x, y_{12}, y_{21}, \tau) \in F\mathbb{U}_{1,r} \times (\mathbb{U}_{1,r} \cap F\mathbb{U}_{1,r}^{-1}) \times (\mathbb{U}_{1,r} \cap F\mathbb{U}_{1,r}^{-1}) \times T_1$ such that

$$\dot{w}^{-1} \tau y_{12} x F(\dot{w}) \in y_{21} F(\mathbb{U}_1 \cap \mathbb{L}_1^{(r)}) .$$
Therefore to prove the lemma, it is enough to analyze the intersection

\[ w^{-1}(U_{1,r} \cap F U_{1,r}^{-1}) \cdot F U_{1,r} F(\hat{w}) \cap \left[ \left( U_{1,r} \cap F U_{1,r}^{-1} \right) \cdot F \left( U_{1} \cap \mathbb{I}_{1}^{(r)} \right) \right]. \]

By construction (see (4.2), (4.3), and write \( F_0(g) = b_0 \gamma t_{k,n} \gamma^{-1} \sigma(g) t_{k,n}^{-1} \beta b_0 \gamma^{-1} \)), we have

\[
\hat{w}^{-1}(T_1 \cap (U_{1,r} \cap F U_{1,r}^{-1}) \cdot F U_{1,r} F(\hat{w}) \cap ((U_{1,r} \cap F U_{1,r}^{-1}) \cdot F U_{1,r})
= \gamma^{-1}(\gamma \hat{w}^{-1} \gamma^{-1})(T_1 \cdot (U_{low,1,r} \cap F_0 U_{up,1,r}) \cdot F_0(U_{low,1,r}) F_0(\gamma \hat{w}^{-1} \gamma^{-1}) \gamma
\cap \gamma^{-1}((U_{low,1,r} \cap F_0 U_{up,1,r}) \cdot F_0(U_{low,1,r}) \gamma).
\]

Now the desired result holds by Chan and Ivanov [8, Lemma 3.5].

The rest of the proof now proceeds exactly as in [8, Section 3.3, 3.4], which we summarize now. By Chan and Ivanov [8, Lemma 3.5], if \( 1 \neq w \in W_{L_h}^{(r)} \) is such that \( \hat{\Sigma}_w \neq \emptyset \), then \( U_h \cap w^{-1} U_h \hat{w} \) is centralized by a subtorus of \( T_h \) which properly contains the center of \( G_h \). In particular, the group

\[ H_w = \{(t, t') \in T_h \times T_h : \hat{w}^{-1} t^{-1} F(t) \hat{w} = t'^{-1} F(t') \text{ centralizes } \mathbb{K}_h = U_h \cap w^{-1} U_h \hat{w} \} \]

has the property that its image under the projections \( \pi_1, \pi_2 : T_h \times T_h \to T_1 \times T_1 \to T_1 \) contains a rank-1 regular\(^1\) torus. Crucially, \( H_w \) acts on \( \hat{\Sigma}_w^{(r)} \) via

\[
(t, t') : (x, y_1, \tau, z, y_2) \mapsto \left( F(t)x F(t)^{-1}, F(t)y_1 F(t)^{-1}, \tau \hat{w} t'^{-1} \right),
\]

and this action extends the action of \( T_h(F_q) \times T_h(F_q) \). Then \( H_w^c(\hat{\Sigma}_w, \Sigma_q^c) = H_w^c(\hat{\Sigma}_w^{H_0}, \Sigma_q^c) \) and using [8, Lemma 3.6], we can calculate:

\[
\hat{\Sigma}_w^{H_0} = \begin{cases} (T_h \hat{w})^F & \text{if } F(\hat{w}) = \hat{w}, \\ \emptyset & \text{otherwise.} \end{cases}
\]

Now (5.3) holds for all \( w \neq 1 \). To obtain (5.3) for \( w = 1 \), we may apply [8, Section 3.4] directly. We have now finished the proof of Theorem 5.2.1

### 5.2.2 Proof of Corollary 5.2.3

Consider

\[
\Sigma^1 = \{(x, x', y) \in \left( \mathbb{U}_h^1 \cap F \mathbb{U}_h^{-1} \right) \times \left( \mathbb{U}_h^1 \cap F \mathbb{U}_h^{-1} \right) \times G_h^1 : x F(y) = y x' \}.
\]

\(^1\) We mean here that this torus is not contained in \( \ker(\alpha) \) for any root \( \alpha \) of \( T_1 \) the reductive group \( G_1 \). See [8, Lemma 3.7].
Then we have an isomorphism

$$G_h(F_q) \setminus ((X_h \cap T_h G_h^1) \times (X_h \cap T_h G_h^1)) \to \Sigma^1, \quad (g, g') \mapsto (g^{-1} F(g), g'^{-1} F(g'), g^{-1} g').$$

Since $G_h^1$ has an Iwahori factorization, any $y \in G_h^1$ can be written uniquely in the form

$$y = y_1' y_2' y_3'' y_4'', \quad y_1' \in U_h \cap F^{-1}(U_h^1), \quad y_2' \in U_h \cap F^{-1}(U_h^{-1}), \quad y_3'' \in T_h \cdot (U_h^{-1} \cap F^{-1} U_h^{-1}), \quad y_4'' \in U_h^{-1} \cap F^{-1} U_h^1.$$

Then our defining equation becomes

$$x F(y_1' y_2' y_3'' y_4'') = y_1' y_2' y_3'' y_4'' x.'$$

By (4.4), every element of $U_h$ can be written uniquely in the form $y'_1 - 1 x F(y'_1)$. We also have $F(y'_2), x' \in U_h \cap F U_h^{-1}$ and we can replace $x'$ by $x' F(y'_2)^{-1}$. Therefore $\Sigma^1$ is the set of tuples $(x', y'_2, y_3'', y_4'') \in (U_h \cap F U_h^{-1}) \times (U_h \cap F^{-1} U_h^{-1}) \times (T_h \cdot (U_h^{-1} \cap F^{-1} U_h^{-1})) \times (U_h^{-1} \cap F^{-1} U_h^1)$ which satisfy

$$y_1'' y_2' x' \in y_2' - 1 U_h F(y'_2) F(y_1'') = U_h F(y'_2) F(y_1'').$$

Now consider the subgroup

$$H := \{(t, t') \in T_h \times T_h : t^{-1} F(t) = t'^{-1} F(t') \text{ centralizes } T_h \cdot (U_h^{-1} \cap F^{-1} U_h^{-1})\}.$$

It is a straightforward check that for any $(t, t') \in H$, the map

$$(x', y'_2, y_3'', y_4'') \mapsto (F(t')^{-1} x' F(t'), t^{-1} y_2' t, t^{-1} y_3'' t', F(t')^{-1} y_4'' F(t'))$$

defines an action of $H$ on $\Sigma^1$. By explicit calculation, one can check that $H$ contains an algebraic torus $T$ over $\mathbb{F}_q$ and that the fixed points of $\Sigma^1$ under $T$ is equal to $T_h(\mathbb{F}_q)$. We therefore have

$$\dim H^*_{\chi}(\Sigma^1, \mathbb{Q}_\ell \chi^{-1}, \chi) = \begin{cases} 1 & \text{if } \chi = \chi', \\ 0 & \text{otherwise}, \end{cases}$$

and this completes the proof.

### 5.3 Very regular elements

Recall that we say that an element $g \in T_h(\mathbb{F}_q) \cong W_h(\mathbb{F}_q^n)^\times$ is very regular if its image in $\mathbb{F}_q^\times$ has trivial $\text{Gal}(\mathbb{F}_q^n/\mathbb{F}_q)$-stabilizer.
Proposition 5.3.1 Let $\theta : T_h(F_q) \to \overline{\mathbb{Q}}_\ell^\times$ be any character. If $g \in T_h(F_q) \subset L_h^{(r)}(F_q)G_h^{1}(F_q)$ is a very regular element, then

$$\text{Tr} \left( g; H_c^{*} \left( X_h \cap L_h^{(r)}G_h^{1} \right)[\theta] \right) = \sum_{\gamma \in \text{Gal}(L/k)[n'/r]} \theta^\gamma(x),$$

where $\text{Gal}(L/k)[n'/r]$ is the unique order-$n'/r$ subgroup of $\text{Gal}(L/k)$.

Proof. Let $g \in T_h(F_q)$ be a very regular element and let $t \in T_h(F_q)$ be any element. Since the action of $(g, t)$ on $X_h \cap L_h^{(r)}G_h^{1}$ is a finite-order automorphism of a separated, finite-type scheme over $F_{q^n}$, by the Deligne–Lusztig fixed point formula,

$$\text{Tr} \left( (g, t)^*; H_c^{*} \left( X_h \cap L_h^{(r)}G_h^{1} \right)[\theta] \right) = \text{Tr} \left( (g_{u}, t_{u})^{*}; H_c^{*} \left( (X_h \cap L_h^{(r)}G_h^{1})^{(g_{s}, t_{s})} \right)[\theta] \right),$$

where $g = gs g_{u}$ and $t = t_{s} t_{u}$ are decompositions such that $g_{s}, t_{s}$ is a power of $g, t$ of $p$-power order and $g_{u}, t_{u}$ is a power of $g, t$ of prime-to-$p$ order.

Recall from Sect. 4.2 that every element $x$ of $X_h \cap L_h^{(r)}G_h^{1}$ is a matrix that is uniquely determined by its first column $(x_1, x_2, \ldots, x_n)$. Furthermore, we have an isomorphism

$$\mathbb{W}_h(F_{q^n})^\times \to T_h(F_q), \quad t \mapsto \text{diag}(t, \sigma^l(t), \sigma^{2l}(t), \ldots, \sigma^{(n-1)l}(t)).$$

Under this identification, for $g, t \in T_h(F_q)$, the element $gtx \in X_h \cap L_h^{(r)}G_h^{1}$ corresponds to the vector $(gt x_1, \sigma^l(g)tx_2, \sigma^{2l}(g)tx_3, \ldots, \sigma^{(n-1)l}(g)tx_n)$. In particular, we see that if $x \in (X_h \cap L_h^{(r)}G_h^{1})^{(g, t)},$ then (for any $i = 1, \ldots, n$) $x_i \neq 0$ implies $t = \sigma^{(i-1)l}(g)^{-1}$. Using the assumption that $g$ is very regular and therefore $g_{s}$ has trivial $\text{Gal}(L/k)$-stabilizer, this implies that $(X_h \cap L_h^{(r)}G_h^{1})^{(g, t)}$ exactly consists of elements corresponding to vectors with a single nonzero entry $x_i$. Now, if $i \equiv 1$ modulo $n_0$, then the corresponding $x$ cannot lie in $X_h$ as then $\text{det}(x) \notin \mathbb{W}_h(F_q)^\times$. On the other hand, if $i \equiv 1$ modulo $n_0$ and $i \equiv 1$ modulo $n_0 r$, then the corresponding $x$ cannot lie in $L_h^{(r)}G_h^{1}$. If $x \in X_h \cap L_h^{(r)}G_h^{1}$ corresponds to $(0, \ldots, 0, x_i, 0, \ldots, 0)$ for some $i \equiv 1$ modulo $n_0 r$, then $x_i$ can be any element of $\mathbb{W}_h(F_{q^n})^\times$. Hence:

$$(X_h \cap L_h^{(r)}G_h^{1})^{(g_{s}, t_{s})} = \begin{cases} b_0^i T_h(F_q) & \text{if } t = \sigma^{(i-1)l}(g)^{-1} \text{ for some } i \equiv 1 \text{ mod } n_0 r, \\ \emptyset & \text{otherwise.} \end{cases}$$

Furthermore, for $g_{u}, t_{u} \in T_h(F_q)$ and $b_0^i x \in (X_h \cap L_h^{(r)}G_h^{1})^{(g_{s}, t_{s})}$,

$$g_{u} \cdot b_0^i x \cdot t_{u} = b_0^i (b_0^{-i} g_{u} b_0^i) x t_{u} = b_0^i \sigma^{(i-1)l}(g_{u}) x t_{u}. \quad \text{We are now ready to put all the above together. We have}$$

Recall that the closed stratum is a maximal variety with respect to \( X \) is the Drinfeld stratum is the unramified very regular element. The same analysis as in \( \text{op. cit.} \) can be performed to obtain a generalization of Proposition 5.3.1 for arbitrary \( G \): for any character \( \theta: \mathbb{T}_h(F_q) \to \overline{\mathbb{Q}}_\ell^\times \), if \( g \in G_{x,0}(\mathcal{O}_k) \) is an unramified very regular element with respect to \( x \) such that \( g \in T(\mathcal{O}_k) \),

\[
\text{Tr}(g; H^*_c(X_h \cap \mathbb{L}_h^r \mathbb{G}_1^1)[\theta]) = \sum_{\gamma \in N_{L,x,0}(\mathcal{O}_k)(T(k) \cap G_{x,0}(\mathcal{O}_k))} \theta^\gamma(g).
\]

6 The closed stratum is a maximal variety

Recall that \( X_h^r \) is the closure of the \( r \)th Drinfeld stratum and that the unique closed Drinfeld stratum is the \( n' \)th Drinfeld stratum

\[
X_{h,n'} = X_h^{(n')} := \{x \in \mathbb{G}_h : x^{-1} \sigma(x) \in \mathbb{U}_r^1\}.
\]

Recall further that \( X_h^{(n')} \) is a finite disjoint union of copies of \( X_h^1 := X_h^{(n')} \cap \mathbb{G}_h^1 \):

\[
X_h^{(n')} = \bigsqcup_{g \in \mathbb{G}_h^1(F_q)} [g] \cdot X_h^1,
\]

where \([g]\) denotes a coset representative in \( \mathbb{G}_h(F_q) \) for \( g \in \mathbb{G}_1(F_q) = \mathbb{G}_h(F_q) / \mathbb{G}_h^1(F_q) \).

For any character \( \theta: \mathbb{T}_h(F_q) \to \overline{\mathbb{Q}}_\ell^\times \), we have an isomorphism of \( \mathbb{G}_h(F_q) \)-representations
The Drinfeld stratification for $GL_n$

$$H^c_i(X^{(n')}_h, \overline{Q}_\ell)[\theta] \cong \text{Ind}_{T_h(F_q)G^1_h(F_q)}^{G_h(F_q)}(H^c_i(X^{(n')}_h \cap T_hG^1_h, \overline{Q}_\ell)[\theta]), \quad \text{for all } i \geq 0.$$ 

Let $\chi := \theta|_{T^1_h(F_q)}$. As $G^1_h(F_q)$-representations,

$$H^c_i\left( X^{(n')}_h \cap T_hG^1_h, \overline{Q}_\ell \right)[\theta] \cong H^c_i\left( X^1_h, \overline{Q}_\ell \right)[\chi], \quad \text{for all } i \geq 0.$$

The subvariety $X^1_h \subset X_h$ is stable under the action of $\Gamma_h := \{(\alpha, \alpha^{-1}) : \alpha \in T_h(F_q)\} \cdot (G^1_h(F_q) \times T^1_h(F_q))$, where the product is viewed as a product of subgroups of $G_h(F_q) \times T_h(F_q)$. Observe that $\Gamma_h \cong \mathbb{F}_q^* \times (G^1_h(F_q) \times T^1_h(F_q))$ and note that $\Gamma_h : \{1\} \times T_h(F_q) = G_h(F_q) \times T_h(F_q)$. Therefore

$$\text{Ind}_{\Gamma_h}^{G_h(F_q) \times T_h(F_q)}(H^c_i(X^1_h, \overline{Q}_\ell)[\chi]) \cong \bigoplus_{\theta'} H^c_i(X_h \cap T_hG^1_h)[\theta'],$$

where $\theta'$ ranges over all characters of $T_h(F_q)$ which restrict to $\chi$ on $T^1_h(F_q)$. The action of $(\zeta, g, t) \in \mathbb{F}_q^* \times (G^1_h(F_q) \times T^1_h(F_q)) \cong \Gamma_h$ on $x \in X^1_h$ is given by

$$(\zeta, g, t) \ast x = \zeta(gx t)\zeta^{-1},$$

where we view $\zeta \in \mathbb{F}_q^*$ as an element of $\mathbb{W}_h(F_q \preceq) \cong T_h(F_q)$.

### 6.1 The nonvanishing cohomological degree

Recall from Sect. 5.1 that any character $\theta : T_h(F_q) \to \overline{Q}_\ell^\times$ has a Howe factorization. For any Howe factorization $\theta = \prod_{i=1}^d \theta_i$ of $\theta$, define a Howe factorization for $\chi := \theta|_{T^1_h(F_q)}$ by

$$\chi = \prod_{i=1}^{d'} \chi_i, \quad \text{where } \chi_i := \theta_i|_{T^1_h(F_q)} \text{ and } d' := \begin{cases} d & \text{if } h_d \geq 2, \\ d - 1 & \text{if } h_d = 1. \end{cases}$$

As in Sect. 5.1, although the characters $\chi_i$ are not uniquely determined, we have two well-defined sequences of integers

$$1 =: m_0 \leq m_1 < m_2 < \cdots < m_d' \leq m_{d'+1} \leq m_{d+1} := n$$

$$h =: h_0 \geq h_1 > h_2 > \cdots > h_d' > h_{d'+1} = h_{d+1} := 1$$

satisfying the divisibility $m_i \mid m_{i+1}$ for $0 \leq i \leq d$.

We state the main result of this section.

**Theorem 6.1.1** Let $\chi : T^1_h(F_q) \cong \mathbb{W}_h(F_q \preceq) \to \overline{Q}_\ell^\times$ be any character. Then

$$H^c_i(X^1_h, \overline{Q}_\ell)[\chi] = \begin{cases} \text{irreducible } G^1_h(F_q)\text{-representation} & \text{if } i = r_\chi, \\ 0 & \text{if } i \neq r_\chi, \end{cases}$$
where
\[ r_\chi = 2(n' - 1) + 2e_\chi + f_\chi \]
\[ e_\chi = \left( \frac{n}{m_{d'}} - 1 \right) (h_{d'} - 1) - \left( \frac{n}{\text{lcm}(m_{d'}, n_0)} - 1 \right) - (h_0 - h_{d'}) + \sum_{t=0}^{d' - 1} \frac{n}{m_t} (h_t - h_{t+1}) \]
\[ f_\chi = \left( n - \frac{n}{m_{d'}} \right) - \left( n' - \frac{n}{\text{lcm}(m_{d'}, n_0)} \right) + \sum_{t=0}^{d' - 1} \left( \frac{n}{m_t} - \frac{n}{m_{t+1}} \right) h_{t+1} \]

Moreover, \( F_{\tau q^n} \) acts on \( H^i_c(X^1_h, \overline{\mathbb{Q}}_\ell) \) as multiplication by \((-1)^i q^{ni/2}\).

The assertion about the action of \( F_{\tau q^n} \) on \( H^i_c(X^1_h, \overline{\mathbb{Q}}_\ell)[\theta] \) is equivalent to saying that \( X^1_h \) is a maximal variety in the sense of Boyarchenko–Weinstein \([2]\); that is, \( \# X^1_h(\mathbb{F}_{q^n}) \) attains its Weil–Deligne bound
\[ \# X^1_h(\mathbb{F}_{q^n}) = \sum_{i \geq 0} (-1)^i \text{Tr}(F_{\tau q^n}; H^i_c(X^1_h, \overline{\mathbb{Q}}_\ell)) \leq \sum_{i \geq 0} q^{ni/2} \dim H^i_c(X^1_h, \overline{\mathbb{Q}}_\ell). \]

For easy reference later, we record the following special case of Theorem 6.1.1.

**Corollary 6.1.2** Let \( \chi : \mathbb{T}^1_h(\mathbb{F}_q) \cong \mathbb{W}^1_h(\mathbb{F}_{q^n}) \to \overline{\mathbb{Q}}_\ell^\times \) be any character with trivial \( \text{Gal}(L/k) \)-stabilizer. Then
\[ H^i_c(X^1_h, \overline{\mathbb{Q}}_\ell)[\chi] = \begin{cases} \text{irreducible} & \text{if } i = r_\chi, \\ 0 & \text{if } i \neq r_\chi, \end{cases} \]

where
\[ r_\chi = n(h - h_1) + h(n - 2) + h_{d'} - (n - n') + \sum_{t=1}^{d' - 1} \frac{n}{m_t} (h_t - h_{t+1}). \]

**Proof** The assumption that \( \chi \) has trivial \( \text{Gal}(L/k) \)-stabilizer is equivalent to the assumption that \( m_{d'} = n \). We see then that the formula for \( r_\chi \) given in Theorem 6.1.1 simplifies as follows:
\[
\begin{align*}
    r_\chi &= 2(n' - 1) + \sum_{t=0}^{d' - 1} 2 \left( \frac{n}{m_t} - 1 \right) (h_t - h_{t+1}) \\
    &\quad + \sum_{t=0}^{d' - 1} \left( \frac{n}{m_t} - \frac{n}{m_{t+1}} \right) (h_{t+1} - 1) - \left( \frac{n}{\text{lcm}(m_t, n_0)} - \frac{n}{\text{lcm}(m_{t+1}, n_0)} \right) \\
    &= 2(n' - 1) - 2(h_0 - h_{d'}) - \left( \frac{n}{m_0} - \frac{n}{m_{d'}} \right) - \left( \frac{n}{\text{lcm}(m_0, n_0)} - \frac{n}{\text{lcm}(m_{d'}, n_0)} \right).
\end{align*}
\]
+ \binom{n}{m_0} (2h_0 - h_1) - \frac{n}{m_{d'}} (h_{d'}) + \sum_{t=1}^{d'-1} \frac{n}{m_t} (h_t - h_{t+1}).

Using the fact that \( h_0 = h \) and \( m_0 = 1 \) by construction, the above expression simplifies to the one given in the statement of the corollary. \( \square \)

### 6.2 Ramified Witt vectors

We give a brief summary of ramified Witt vectors, following [5, Section 3.1]. In this section, we assume \( k \) has characteristic 0. We first define a “simplified version” of the ramified Witt ring \( W \).

**Definition 6.2.1** For any \( \mathbb{F}_q \)-algebra \( A \), let \( W(A) \) be the set \( A^N \) endowed with the following coordinatewise addition and multiplication rule:

\[
[a_i]_{i \geq 0} + _W [b_i]_{i \geq 0} = [a_i + b_i]_{i \geq 0},
\]

\[
[a_i]_{i \geq 0} \ast_W [b_i]_{i \geq 0} = \left( \sum_{j=0}^i a_j^{q^i-j} b_j^{q^i-j} \right)_{i \geq 0}.
\]

It is a straightforward check that \( W \) is a commutative ring scheme over \( \mathbb{F}_q \). It comes with Frobenius and Verschiebung morphisms \( \varphi \) and \( V \).

The relationship between the ring scheme \( W \) and the ring scheme \( \mathbb{W} \) of ramified Witt vectors is captured by the following lemma. The key point here is the notion of “major contribution” and “minor contribution”; this will appear in Lemma 6.3.3 and (implicitly) in Proposition 6.4.4.

**Lemma 6.2.2** Let \( A \) be an \( \mathbb{F}_q \)-algebra.

(a) For any \( [a_1], \ldots, [a_n] \in A^N \) where \( [a_j] = [a_{j,i}]_{i \geq 0} \).

\[
\prod_{1 \leq j \leq n} [a_j] = \left( \prod_{1 \leq j \leq n} [a_j] \right) +_W [c],
\]

where \( [c] = [c_i]_{i \geq 0} \) for some \( c_i \in A[a_{1,i}, \ldots, a_{n,i} : i_1 + \cdots + i_n < i, e_1, \ldots, e_n \in \mathbb{Z}_{\geq 0}] \).

(b) For any \( [a_1], \ldots, [a_n] \in A^N \) where \( [a_j] = [a_{j,i}]_{i \geq 0} \).

\[
\sum_{1 \leq j \leq n} [a_j] = \left( \sum_{1 \leq j \leq n} [a_j] \right) +_W [c],
\]

where \( [c] = [c_i]_{i \geq 0} \) for some \( c_i \in A[a_{1,j}, \ldots, a_{n,j} : j < i] \).
We call the portion coming from W the “major contribution” and \([c]\) the “minor contribution.”

### 6.3 Normed indexing sets

The group \(G^1_h\) is an affine space of dimension \(n^2(h - 1)\). To prove Theorem 6.1.1, we will need to coordinatize \(G^1_h\), and we do this here by defining an indexing set \(A^+\) of triples \((i, j, l)\). Our strategy for approaching Theorem 6.1.1 is to perform an inductive calculation based on a Howe factorization of the character \(\chi: T^1_h(\mathbb{F}_q) \to \mathbb{Q}_l^\times\). In this section, we will also define a filtration of \(A^+\) corresponding to the two sequences \(\{m_i\},\{h_i\}\) associated with \(\chi\).

The algebraic group \(G^1_h\) can be described very explicitly: it consists of matrices \((A_{i,j})_{1 \leq i, j \leq n}\) where

\[
A_{i,j} = \begin{cases}
[1, A_{(i,j,1)}, A_{(i,j,2)}, \ldots, A_{(i,j,h-1)}] \in \mathbb{W}_h^1 & \text{if } i = j, \\
[A_{(i,j,0)}, A_{(i,j,1)}, \ldots, A_{(i,j,h-2)}] \in \mathbb{W}_{h-1} & \text{if } [i]_{n_0} > [j]_{n_0}, \\
[0, A_{(i,j,1)}, A_{(i,j,2)}, \ldots, A_{(i,j,h-1)}] \in \mathbb{W}_h & \text{if } [i]_{n_0} \leq [j]_{n_0} \text{ and } i \neq j.
\end{cases}
\]

Here, we recall that for \(x \in \mathbb{Z}\), we write \([x]_{n_0}\) to denote the unique representative of \(x\mathbb{Z}/n_0\mathbb{Z}\) in the set of coset representatives \(\{1, \ldots, n_0\}\). We have a well-defined determinant map

\[
det: G^1_h \to \mathbb{W}_h^1.
\]

In the way described above, \(G^1_h\) can be coordinatized by the indexing set

\[
A^+ := \left\{(i, j, l) \in \mathbb{Z}^{\oplus 3} : 0 \leq l \leq h - 2 \text{ if } [i]_{n_0} > [j]_{n_0}, 1 \leq l \leq h - 1 \text{ if } [i]_{n_0} \leq [j]_{n_0} \right\}.
\]

We also define:

\[
A := \{(i, j, l) \in A^+: i \neq j\},
\]

\[
A^- := \{(i, j, l) \in A : j = 1\}.
\]

The indexing set \(A\) corresponds to the elements of \(G^1_h\) with 1’s along the diagonal, and \(A^-\) remembers only the first column of elements of \(G^1_h\) with \((1, 1)\)-entry 1.

**Definition 6.3.1** Define a norm on \(A^+\):

\[
A^+ \to \mathbb{R}_{\geq 0},
\]

\[
(i, j, l) \mapsto |(i, j, l)| := i - j + nl.
\]

**Definition 6.3.2** For \(\lambda = (i, j, l) \in A^+\), define

\[
\lambda^\vee := (j, i, h - 1 - l).
\]
The following seemingly innocuous lemma is in some sense the key reason that the indexing sets above allow us to carry over the calculations in [5, Section 5] from \( n' = 1 \) setting to the present general \( n' \) setting with very few modifications.

**Lemma 6.3.3** Following the conventions as set up above, write \( A = (A_{i,j})_{1 \leq i,j \leq n} \in \mathcal{A}^1_h \), where

\[
A_{i,j} = \begin{cases} 
[1, A(i,j,1), \ldots, A(i,j,h-1)] \in \mathbb{W}^1_h & \text{if } i = j, \\
[A(i,j,0), \ldots, A(i,j,h-2)] \in \mathbb{W}_{h-1} & \text{if } [i]_{n_0} > [j]_{n_0}, \\
[0, A(i,j,1), \ldots, A(i,j,h-1)] \in \mathbb{W}_h & \text{if } [i]_{n_0} \leq [j]_{n_0} \text{ and } i \neq j.
\end{cases}
\]

Assume that for \( \lambda_1, \lambda_2 \in \mathcal{A}^+ \), the variables \( A_{\lambda_1} \) and \( A_{\lambda_2} \) appear in the same monomial in \( \det(A) \in \mathbb{W}_{h'} \) for some \( h' \leq h \).

(a) Then \( |\lambda_1| + |\lambda_2| \leq n(h' - 1) \).

(b) If \( |\lambda_1| + |\lambda_2| = n(h' - 1) \), then \( \lambda_2 = \lambda_1^\vee \), where \( \vee \) is taken relative to \( h' \).

**Proof** By definition,

\[
\det(A) = \sum_{\gamma \in S_n} \prod_{1 \leq i \leq n} A_{i,\gamma(i)} \in \mathbb{W}_{h'}(\mathbb{F}_q).
\]

Let \( l \leq h' - 1 \). If \( K \) has characteristic \( p \), then the contributions to the \( \varpi^l \)-coefficient coming from \( \gamma \in S_n \) are of the form

\[
\prod_{i=1}^n A_{i,\gamma(i),l_i},
\]

where \( (l_1, \ldots, l_n) \) is a partition of \( l \). Then

\[
\sum_{i=1}^n |(i, \gamma(i), l_i)| = \sum_{i=1}^n i - \gamma(i) + nl_i = \sum_{i=1}^n nl_i = nl \leq n(h' - 1). \tag{6.1}
\]

If \( K \) has characteristic 0, then the major contributions to the \( \varpi^l \)-coefficient coming from \( \gamma \) are of the form

\[
\prod_{i=1}^n A_{i,\gamma(i),l_i}^{e_i},
\]

where the \( e_i \) are some nonnegative integers and where \( (l_1, \ldots, l_n) \) is a partition of \( l \). Hence

\[
\sum_{i=1}^n |(i, \gamma(i), l_i)| = nl \leq n(h' - 1). \tag{6.2}
\]

The minor contributions to the \( \varpi^l \)-coefficient coming from \( \gamma \) are polynomials in

\[
\prod_{i=1}^n A_{(i,\gamma(i),l_i)}^{e_i}
\]

where \( l_1 + \cdots + l_n < l \) and the \( e_i \) are some nonnegative integers. Hence \( \sum_{i=1}^n |(i, \gamma(i), l_i)| < n(h' - 1) \).
Suppose now that \( \lambda_1 = (i_1, j_1, l_1), \lambda_2 = (i_2, j_2, l_2) \in A^+ \) are such that \( A_{\lambda_1} \) and \( A_{\lambda_2} \) contribute to the same monomial in \( \det(M) \in \mathbb{W}_h^{\prime} \). Then there exists some \( \gamma \in S_m \) such that \( \gamma(i_1) = j_1 \) and \( \gamma(i_2) = j_2 \), and by Eqs. (6.1) and (6.2),

\[
|\lambda_1| + |\lambda_2| \leq n(h' - 1).
\]

Observe that if \( K \) has characteristic 0 and \( \lambda_1 \) and \( \lambda_2 \) occur in a minor contribution, then \( |\lambda_1| + |\lambda_2| < n(h') \). This proves (a), and furthermore, we see that if \( |\lambda_1| + |\lambda_2| = n(h' - 1) \), then the simultaneous contribution of \( A_{\lambda_1} \) and \( A_{\lambda_2} \) comes from a major contribution. But now (b) follows: since the image of \( G^1_h \) under the determinant is \( \mathbb{W}_h^{\prime} \), if \( |\lambda_1| + |\lambda_2| = n(h' - 1) \), then necessarily the contribution of \( \lambda_1 \) and \( \lambda_2 \) to the \( (h' - 1) \)th coordinate of the determinant must come from a transposition.

Given two sequences of integers

\[
1 =: m_0 \leq m_1 < m_2 < \cdots < m_{d'} \leq m_{d'+1} \leq m_{d+1} =: n
\]

\[
h =: h_0 \geq h_1 > h_2 > \cdots > h_{d'} > h_{d'+1} = h_{d+1} =: 1
\]

satisfying \( m_i \mid m_{i+1} \) for \( 0 \leq i \leq d \), we can define the following subsets of \( A \) for \( 0 \leq s, t \leq d \):

\[
A_{s,t} := \{(i, j, l) \in A : i \equiv j \pmod{m_s}, i \not\equiv j \pmod{m_{s+1}}, l \leq h_t - 1 \},
\]

\[
A_{s,t}^- := A_{s,t} \cap A^-.
\]

We will need to understand which \( \lambda \in A \) are such that \( x_\lambda \) contributes nontrivially to the determinant. We denote the set of all such \( \lambda \) by \( A_{\min} \). We may describe this explicitly:

\[
A_{\min} = \{ \lambda \in A : \lambda^\triangledown \in A \}
\]

\[
= \left\{ (i, j, l) \in A : \begin{array}{l}
0 \leq l \leq h - 2 \text{ if } [i]_{n_0} > [j]_{n_0} \\
1 \leq l \leq h - 1 \text{ if } [i]_{n_0} < [j]_{n_0} \\
1 \leq l \leq h - 2 \text{ if } [i]_{n_0} = [j]_{n_0}
\end{array} \right\}.
\]

(6.3)

For \( 0 \leq s, t \leq r \), by considering \( \triangledown \) relative to \( h_t \), we may similarly define

\[
A_{s,t}^{\min} := \{ \lambda \in A_{s,t} : \lambda^\triangledown \in A_{s,t} \}
\]

\[
= \left\{ (i, j, l) \in A_{s,t} : \begin{array}{l}
0 \leq l \leq h_t - 2 \text{ if } [i]_{n_0} > [j]_{n_0} \\
1 \leq l \leq h_t - 1 \text{ if } [i]_{n_0} < [j]_{n_0} \\
1 \leq l \leq h_t - 2 \text{ if } [i]_{n_0} = [j]_{n_0}
\end{array} \right\}.
\]
Define $A_{s,t}^{-,\text{min}} := A^- \cap A_{s,t}^{\text{min}} = A_{s,t}^- \cap A_{s,t}^{\text{min}}$. Define the following decomposition of $A_{s,t}^{-,\text{min}}$:

$$
\mathcal{I}_{s,t} := \{(i,1,l) \in A_{s,t}^{-,\text{min}} : |(i,1,l)| > n(h_t - 1)/2\},
$$

$$
\mathcal{J}_{s,t} := \{(i,1,l) \in A_{s,t}^{-,\text{min}} : |(i,1,l)| \leq n(h_t - 1)/2\}.
$$

For any real number $v$, define

$$
A_{v,t}^{-,\text{min}} := \bigsqcup_{s=\lfloor v \rfloor}^{r} A_{s,t}^{-,\text{min}}, \quad A_{\geq v,t}^{-,\text{min}} = A^- \cap A_{\geq v,t}^{-,\text{min}},
$$

and observe that for $0 \leq s \leq r$ an integer,

$$
A_{\geq s,t}^{-,\text{min}} = \begin{cases}
(i, j, l) \in A : & j \equiv i \pmod{m_s} \\
0 \leq l \leq h_t - 2 & \text{if } |i|_{n_0} > |j|_{n_0} \\
1 \leq l \leq h_t - 1 & \text{if } |i|_{n_0} < |j|_{n_0} \\
1 \leq l \leq h_t - 2 & \text{if } |i|_{n_0} = |j|_{n_0}
\end{cases}.
$$

**Lemma 6.3.4** There is an order-reversing injection $\mathcal{I}_{s,t} \hookrightarrow \mathcal{J}_{s,t}$ that is a bijection if and only if $A_{s,t}^{-,\text{min}}$ is even. Explicitly, it is given by

$$
\mathcal{I}_{s,t} \hookrightarrow \mathcal{J}_{s,t}, \quad (i,1,l) \mapsto ([n-i+2]_n, 1, h_t - 2 - l).
$$

Note that $\# A_{s,t}^{-,\text{min}}$ is even unless $n$ and $h_t$ are both even.

**Proof** If $(i,1,l) \in A_{s,t}^{-,\text{min}}$, then by definition $i \equiv 1 \pmod{m_s}$ and $i \not\equiv 1 \pmod{m_{s+1}}$. Thus $[n-i+2]_n \equiv 1 \pmod{m_s}$ and $[n-i+2]_n \not\equiv 1 \pmod{m_{s+1}}$, which shows that $(i,1,l) \in A_{s,t}^{-,\text{min}}$ implies $([n-i+2]_n, 1, l) \in A_{s,t}^{-,\text{min}}$. Since $i \geq 2$ by assumption, we have $i + [n-i+2]_n = n + 2$ and

$$
|(i,1,l)| + |([n-i+2]_n, 1, h_t - 2 - l)| = n(h_t - 1).
$$

Hence if $(i,1,l) \in \mathcal{I}_{s,t}$, then $([n-i+2]_n, 1, l) \in \mathcal{J}_{s,t}$. It is clear that the map is a bijection if and only if $\mathcal{J}_{s,t}$ does not contain an element of norm $n(h_t - 1)/2$. Such an element must necessarily be of the form $((n+2)/2, 1, (h_t - 2)/2)$, which is integral if and only if $n$ and $h_t$ are both even. \hfill $\square$

### 6.4 The cohomology of $X_h^1$

The purpose of this section is to establish the following result:

**Theorem 6.4.1** For any character $\chi : \mathbb{T}_h^1(\mathbb{F}_q) \to \mathbb{Q}_\ell^\times$, 

For any character $\chi$ and $j \in \mathbb{Z}$, we have

$$\text{Hom}_{\mathbb{G}_a^1(F_q)} \left( \text{Ind}^{\mathbb{G}_a^1(F_q)}_{\mathbb{G}_m^1(F_q)}(\chi), H^j_c(X, \mathbb{Q}_\ell) \right) = \begin{cases} \mathbb{Q}_\ell^\times / q^{j/2} \otimes (-q^{j/2} y)^{\deg i} & \text{if } i = r, \\ 0 & \text{otherwise.} \end{cases}$$

Moreover, $\text{Fr}_{q^n}$ acts on $H^j_c(X_{\mathbb{Q}^r}, \mathbb{Q}_\ell)$ by multiplication by the scalar $(-1)^j q^{nt/2}$.

This is a technical calculation which follows the strategy developed in [5] (in particular, see Sections 4 and 5 of op. cit.). We first rephrase space of homomorphisms in the statement of Theorem 6.4.1 in terms of the cohomology of a related variety. Every coset of $\mathbb{G}_a^1 / \mathbb{T}_h^1$ has a unique coset representative $g$ whose diagonal entries are identically 1. Over $F_q$, we may identify $\mathbb{G}_a^1 / \mathbb{T}_h^1$ with the affine space $\mathbb{A}[\mathbb{A}]$ (the affine space of dimension $\# \mathbb{A}$ with coordinates indexed by the set $\mathbb{A}$ of Sect. 6.3). Then the quotient morphism $\mathbb{G}_a^1 \to \mathbb{G}_a^1 / \mathbb{T}_h^1$ has a section given by

$$s : \mathbb{G}_a^1 / \mathbb{T}_h^1 \to \mathbb{G}_a^1, \quad (x, y) \mapsto (s_i(i) y)_{i=1,...,n},$$

where

$$x_i = \begin{cases} 1 \in \mathbb{W}_h^1 & \text{if } i = j, \\ [x(i,j,0), x(i,j,1), \ldots, x(i,j,h-2)] \in \mathbb{W}_{h-1} & \text{if } [i]_n > [j]_n, \\ [0, x(i,j,1), x(i,j,2), \ldots, x(i,j,h-1)] \in \mathbb{W}_h & \text{if } [i]_n \leq [j]_n \text{ and } i \neq j. \end{cases}$$

As in [5, Section 5.1.1], there exists a closed $F_q^n$-subscheme $Y_h^1$ of $\mathbb{G}_a^1$ such that $X_h = L_q^1(Y_h^1)$ which satisfies the condition that $\text{Fr}_{q^n}^j(Y_h^1) \cap \text{Fr}_{q}^j(Y_h^1) = \{1\}$ for all $i \neq j$. We are therefore in a setting where we can invoke [5, Proposition 4.1.1].

Define

$$\beta : (\mathbb{G}_a^1 / \mathbb{T}_h^1) \times \mathbb{T}_h^1 \to \mathbb{G}_a^1, \quad (x, g) \mapsto s(\text{Fr}_q(x)) \cdot g \cdot s(x).$$

The affine $F_q^n$-scheme $\beta^{-1}(Y_h^1) \subset (\mathbb{G}_a^1 / \mathbb{T}_h^1) \times \mathbb{T}_h^1$ comes with two maps:

$$\text{pr}_1 : \beta^{-1}(Y_h^1) \to \mathbb{G}_a^1 / \mathbb{T}_h^1 = \mathbb{A}[\mathbb{A}], \quad \text{pr}_2 : \beta^{-1}(Y_h^1) \to \mathbb{T}_h^1.$$

Recall from [5, Lemma 4.1.2] that since the Lang morphism $L_q$ is surjective,

$$\begin{equation}
(x, g) \in \beta^{-1}(Y_h^1) \iff s(x) \cdot y \in X_h,
\end{equation}$$

where $y \in \mathbb{T}_h^1$ is any element such that $L_q(y) = g$.

**Proposition 6.4.2** For any character $\chi : \mathbb{T}_h^1(F_q) \cong \mathbb{W}_h^1(F_q^n) \to \mathbb{Q}_\ell^\times$, let $\mathcal{L}_\chi$ denote the corresponding $\mathbb{Q}_\ell$-local system on $\mathbb{W}_h^1$. For $i \geq 0$, we have $\text{Fr}_{q^n}$-compatible isomorphisms

$$\text{Hom}_{\mathbb{G}_a^1(F_q)} \left( \text{Ind}^{\mathbb{G}_a^1(F_q)}_{\mathbb{G}_m^1(F_q)}(\chi), H^i_c(X, \mathbb{Q}_\ell) \right) \cong H^i_c(\mathbb{A}[\mathbb{A}^{-}], P^* \mathcal{L}_\chi).$$
where $P : \mathbb{A}[\mathcal{A}^\ast] \to \mathbb{W}_h^1$ is the morphism $(x(i,1,i))_{i(1,1) \in \mathcal{A}^\ast} \mapsto L_q(\det(g_b^{\text{red}}(1, x_2, \ldots, x_n)))^{-1}\text{ for } x_i := [x(i,1,0), x(i,1,1), \ldots, x(i,1,h-1)].$

**Proof** By [5, Proposition 4.1.1],

$$\text{Hom}_{\mathbb{G}_m^1(\mathbb{F}_q)}(\text{Ind}_{\mathbb{G}_m^1(\mathbb{F}_q)}(\chi), H^i_c(X_h, \overline{\mathbb{Q}}) \equiv H^i_c(\beta^{-1}(Y_h^1), \text{pr}^*_2 \mathcal{F}_\chi),$$

where $\mathcal{F}_\chi$ is the rank-1 local system on $\mathbb{T}_h^1$ corresponding to $\chi$. By the same proof as [5, Lemma 5.1.1], $\beta^{-1}(Y_h^1)$ is the graph of the morphism $P_0 : \mathbb{A}[\mathcal{A}] \to \mathbb{W}_h^1$ given by $x \mapsto L_q(\det(s(x))^{-1})$. Furthermore, as morphisms on $\beta^{-1}(Y_h^1)$, we have $\text{pr}_2 = i \circ P_0 \circ \text{pr}_1$, where $i : \mathbb{W}_h^1 \to \mathbb{T}_h^1, x \mapsto \text{diag}(x, 1, \ldots, 1)$. Therefore, as sheaves on $\text{pr}_1(\beta^{-1}(Y_h^1))$, we have $\text{pr}^*_2 \mathcal{F}_\chi = P_0^* i^* \mathcal{F}_\chi = P_0^* \mathcal{L}_\chi$, so

$$H^i_c(\beta^{-1}(Y_h^1), \text{pr}^*_2 \mathcal{F}_\chi) = H^i_c(\text{pr}_1(\beta^{-1}(Y_h^1)), P_0^* \mathcal{L}_\chi).$$

Next we claim that the projection $\mathbb{A}[\mathcal{A}] \to \mathbb{A}[\mathcal{A}^\ast]$ induces an isomorphism $\text{pr}_1(\beta^{-1}(Y_h^1)) \to \mathbb{A}[\mathcal{A}^\ast]$. Injectivity is clear: using (6.4), we know that $x \in \text{pr}_1(\beta^{-1}(Y_h^1))$ if $s(x) \cdot y \in X_h^1$ for some $y \in \mathbb{T}_h^1$. Since $s(x) \cdot y$ is uniquely determined by its first column, then $s(x)$ is uniquely determined by its first column, which is precisely the projection of $x$ to $\mathbb{A}[\mathcal{A}^\ast]$. To see surjectivity, we need to show that for any $x \in \mathbb{A}[\mathcal{A}^\ast](\overline{\mathbb{F}}_q)$, there exists a $y \in \mathbb{T}_h^1(\overline{\mathbb{F}}_q)$ such that $g_b^{\text{red}}(x) \cdot y \in X_h^1$. Pick any $y = \text{diag}(y_1, \sigma(y_1), \ldots, \sigma(y_1)) \in \mathbb{T}_h^1(\overline{\mathbb{F}}_q)$ such that $\det(y) = \det(g_b^{\text{red}}(x))^{-1}$. Then $g_b^{\text{red}}(x) \cdot y \in X_h$ since $g_b^{\text{red}}(x) \cdot y = g_b^{\text{red}}(xy_1)$ and $\det(g_b^{\text{red}}(x) \cdot y) = 1 \in \mathbb{W}_h^1(\overline{\mathbb{F}}_q)$. Under the isomorphism $\text{pr}_1(\beta^{-1}(Y_h^1)) \cong \mathbb{A}[\mathcal{A}^\ast]$, the sheaf $P_0^* \mathcal{L}_\chi$ is identified with $P^* \mathcal{L}_\chi$, and the proposition now follows. \hfill $\Box$

Note that the last paragraph of the above proof is a simpler and more conceptual proof of [5, Lemma 5.1.6]. To calculate $H^i_c(\mathbb{A}[\mathcal{A}^\ast], P^* \mathcal{L}_\chi)$, we will use an inductive argument on affine fibrations that relies on iteratively applying the next two propositions:

**Proposition 6.4.3** For $0 \leq t \leq d'$, we have $\text{Fr}_{q^n}$-compatible isomorphisms

$$H^i_c(\mathbb{A}[\mathcal{A}_{\geq t,t}^\text{min}], P^* \mathcal{L}_{\chi_{\geq t}}) \cong H^i_c(\mathbb{A}[\mathcal{A}_{\geq t,t+1}^\text{min}], P^* \mathcal{L}_{\chi_{\geq t+1}})[2e_t] \otimes ((- q^{n/2})^{2e_t})^{\text{deg}},$$

where $e_t = \#(\mathcal{A}_{\geq t,t}^\text{min} \setminus \mathcal{A}_{\geq t,t+1}^\text{min})$.

**Proof** The proof is the same as the proof of [5, Proposition 5.3.1]. We give a sketch here. By definition, $\chi_{\geq t} = \chi_t \cdot \chi_{t+1}$ and $\chi_t$ factors through the norm map $\mathbb{W}_h^1(\overline{\mathbb{F}}_{q^n}) \to \mathbb{W}_h^1(\overline{\mathbb{F}}_{q^{m_t}})$. Let $p : \mathbb{W}_h^1 \to \mathbb{W}_h^1$. Since $P : \mathbb{A}[\mathcal{A}_{\geq t,t}^\text{min}] \to \mathbb{W}_h^1$ factors through $L_{q^{m_t}}$, this implies that

$$P^* \mathcal{L}_{\chi_{\geq t}} = P^* \mathcal{L}_{\chi_t} \otimes P^* \text{pr}^* \mathcal{L}_{\chi_{\geq t+1}} = \overline{\mathbb{Q}}^{\ell} \otimes P^* \mathcal{L}_{\chi_{\geq t+1}},$$
Proof of Theorem 6.4.1

For $0 \leq t \leq d' - 1$, we have $\Fr_{q^n}$-compatible isomorphisms

$$H^i_c\left(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_{X_{\geq t+1}}\right) \cong H^i_c\left(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_{X_{\geq t+1}}\right) \oplus q^{n/2} [f_i] \otimes \left(-q^{n/2} f_i \right)^{\deg},$$

where $f_i = \#(A_{-\min} \setminus A_{-\min}) = \#A_{-\min}$.

Proposition 6.4.4

For $0 \leq t \leq d'-1$, we have $\Fr_{q^n}$-compatible isomorphisms

$$H^i_c\left(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_{X_{\geq t+1}}\right) \cong H^i_c\left(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_{X_{\geq t+1}}\right) \oplus q^{n/2} [f_i] \otimes \left(-q^{n/2} f_i \right)^{\deg},$$

where $f_i = \#(A_{-\min} \setminus A_{-\min}) = \#A_{-\min}$.

Proof

By replacing [5, Lemmas 3.2.3, 3.2.6] with Lemmas 6.3.3 and 6.3.4, the proof of [5, Proposition 5.3.2] applies. (The proof is quite technical; simpler incarnations of this idea have appeared in [1, 3, 4].)

Proof of Theorem 6.4.1

By Proposition 6.4.2, we need to calculate $H^i_c(\mathbb{A}[A^-], P^*\mathcal{L}_X)$. Since $P(\mathbb{A}[A^- \setminus A_{-\min}]) = \{1\} \in \mathbb{W}^1_h$ and $\#(A^- \setminus A_{-\min}) = n' - 1$, we see that

$$H^i_c(\mathbb{A}[A^-], P^*\mathcal{L}_X) = H^i_c(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_X)[2(n'-1)] \otimes \left(-q^{n/2}\right)^{2(n'-1)} \deg.$$ 

Using Propositions 6.4.3 and 6.4.4 iteratively, we have

$$H^i_c(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_X) = H^i_c(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_X) \oplus q^{n/2} [f_0] \otimes \left(-q^{n/2} f_0 \right)^{\deg} \text{ (by def)}$$

$$\cong H^i_c(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_{X_{\geq 0}}) \oplus q^{n/2} [f_0] \otimes \left(-q^{n/2} f_0 \right)^{\deg} \text{ (Prop 6.4.3)}$$

$$\cong H^i_c(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_{X_{\geq 1}}) \oplus q^{n/2} [f_0 + 2e_0] \otimes \left(-q^{n/2} f_0 + 2e_0 \right)^{\deg} \text{ (Prop 6.4.4)}$$

$$\cong H^i_c(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_{X_{\geq 2}}) \oplus q^{n/2} [f_0 + 2(e_0 + e_1)] \otimes \left(-q^{n/2} f_0 + 2(e_0 + e_1) \right)^{\deg} \text{ (Prop 6.4.3)}$$

and so forth until

$$\cong H^i_c(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_{X_{\geq d',d'+1}}) \oplus q^{n/2} [f_{d'} + 2e_{d'}] \otimes \left(-q^{n/2} f_{d'} + 2e_{d'} \right)^{\deg},$$

where

$$f_{d'} := f_0 + f_1 + \cdots + f_{d'-1}, \quad e_{d'} := e_0 + e_1 + \cdots + e_{d'}.$$

Since $A_{\geq d',d'+1} = \emptyset$, now we have shown

$$H^i_c(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_X) \cong H^i_c(\mathbb{A}[A_{-\min}], P^*\mathcal{L}_X) \oplus q^{n/2} [f_{d'} + 2e_{d'}] \otimes \left(-q^{n/2} f_{d'} + 2e_{d'} \right)^{\deg}. \quad (6.5)$$

Set $r_X := 2(n' - 1) + f_{d'} + 2e_{d'}$. By Proposition 6.4.2, we now have

$$\Hom_{G^1_f(P_q)} \left( \Ind_{G^1_f(P_q)}(\chi), H^i_c(X_h, \overline{G^1_f}) \right) \cong \begin{cases} \overline{G^1_f}^{n/2} & \text{if } i = r_X, \\ 0 & \text{otherwise.} \end{cases}$$
Moreover, since Fr\textsubscript{q\textsuperscript{n}} acts trivially on \( H^i_c(\mathbb{A}_{\geq 2d',d'+1}^\infty, \mathbb{P}^*\mathcal{L}_{X_{\geq d'+1}}^\infty) = H^0(\ast, \overline{\mathbb{Q}_\ell}) \), then Fr\textsubscript{q\textsuperscript{n}} acts by multiplication by \((-1)^{\chi} q^{nr\chi/2}\) on the above space of homomorphisms.

To finish the proof of Theorem 6.4.1, we need only calculate \( e_\chi, f_\chi, r_\chi \). Unwinding the definitions of indexing sets given in Sect. 6.3, we have, for \( 0 \leq t \leq d' \),

\[
\begin{align*}
A_{\geq t, t+1}^- & = \left\{ (i, 1, l) \in \mathbb{Z}^3 : 2 \leq i \leq n, i \equiv 1 \pmod{m_t}, 0 \leq l \leq h_t - 2 \text{ if } [i]_{n_0} \neq 1, \\
& \quad 1 \leq l \leq h_t - 2 \text{ if } [i]_{n_0} = 1 \right\}.
\end{align*}
\]

Therefore, we have

\[
e_t = \left( \frac{n}{m_t} - 1 \right) (h_t - h_{t+1}) \quad \text{if } 0 \leq t \leq d' - 1,
\]

\[
e_{d'} = \left( \frac{n}{m_{d'}} - 1 \right) (h_{d'} - 1) - \left( \frac{n}{\text{lcm}(m_{d'}, n_0)} - 1 \right).
\]

For \( 0 \leq t \leq d' - 1 \), we have

\[
A_{t, t+1}^- = \left\{ (i, 1, l) \in \mathbb{Z}^3 : 2 \leq i \leq n, i \equiv 1 \pmod{m_t}, i \not\equiv 1 \pmod{m_{t+1}}, 0 \leq l \leq h_{t+1} - 2 \text{ if } [i]_{n_0} \neq 1, \\
& \quad 1 \leq l \leq h_{t+1} - 2 \text{ if } [i]_{n_0} = 1 \right\}
\]

so that

\[
f_t = \left( \frac{n}{m_t} - \frac{n}{m_{t+1}} \right) (h_{t+1} - 1) - \left( \frac{n}{\text{lcm}(m_t, n_0)} - \frac{n}{\text{lcm}(m_{t+1}, n_0)} \right). \quad \square
\]

### 6.5 The nonvanishing cohomological degree

In this section, we use the results of the preceding sections to finish the proof of Theorem 6.1.1. Observe that from Theorem 6.4.1 together with Corollary 5.2.2, we have the following:

**Corollary 6.5.1** Let \( \pi \) be an irreducible constituent of \( H^i_c(Z_{h}^1, \overline{\mathbb{Q}_\ell}) \) for some \( r \). Then

\[
\text{Hom}_{\mathbb{G}_a(\mathbb{F}_q)} \left( \pi, H^i_c(X_{h}^1, \overline{\mathbb{Q}_\ell}) \right) = 0 \quad \text{for all } i \neq r.
\]

In particular, for any \( \chi : T_{h}^1(\mathbb{F}_q) \to \overline{\mathbb{Q}_\ell}^\times \), there exists a positive integer \( s_\chi \) such that

\[
H^i_c(X_{h}^1, \overline{\mathbb{Q}_\ell})[\chi] = \begin{cases} 
\text{irreducible} & \text{if } i = s_\chi, \\
0 & \text{if } i \neq s_\chi.
\end{cases}
\]
Proof This is the same as the proof of [5, Corollary 5.1.3]. The irreducible $G^1_h(\mathbb{F}_q)$-representation $\pi \subset H^r_c(X_h^1, \overline{\mathbb{Q}}_\ell)$ is a summand of $\text{Ind}_{T^1_h(\mathbb{F}_q)}^{G^1_h(\mathbb{F}_q)}(\chi')$ for some $\chi'$. Hence

$$\text{Hom}_{G^1_h(\mathbb{F}_q)}\left(\text{Ind}_{T^1_h(\mathbb{F}_q)}^{G^1_h(\mathbb{F}_q)}(\chi'), H^r_c(X_h^1, \overline{\mathbb{Q}}_\ell)\right) \neq 0.$$  

Theorem 6.4.1 implies that $r = r_{\chi'}$ and that there are no $G^1_h(\mathbb{F}_q)$-equivariant homomorphisms from $\pi$ to $H^i_c(X_h^1, \overline{\mathbb{Q}}_\ell)$ for $i \neq r_{\chi'}$. This proves the first assertion.

To see the second assertion, first recall from Corollary 5.2.2 that $H^*_c(X_h^1, \overline{\mathbb{Q}}_\ell)[\chi]$ is (up to sign) an irreducible $G^1_h(\mathbb{F}_q)$-representation. Therefore, we may apply the above argument to $H^*_c(X_h^1, \overline{\mathbb{Q}}_\ell)[\chi]$ and we see that if $H^*_c(X_h^1, \overline{\mathbb{Q}}_\ell)[\chi]$ is a summand of $\text{Ind}_{T^1_h(\mathbb{F}_q)}^{G^1_h(\mathbb{F}_q)}(\chi')$, then

$$H^*_c(X_h^1, \overline{\mathbb{Q}}_\ell)[\chi] = \begin{cases} \text{irreducible} & \text{if } i = r_{\chi'}, \\ 0 & \text{otherwise}. \end{cases}$$

Since the number $r_{\chi'}$ only depends on $\chi$, we final assertion of the corollary holds taking $s_{\chi} = r_{\chi'}$.  

We see now that the upshot of Theorem 6.4.1 is that we already know that $H^*_c(X_h^1, \overline{\mathbb{Q}}_\ell)[\chi]$ is concentrated in a single degree $s_{\chi}$. However, it would be much more satisfying—for many reasons, computational, conceptual, ideological—if we could pinpoint this nonvanishing cohomological degree. Taking a hint from the proof of Corollary 6.5.1, one strategy to prove that $s_{\chi} = r_{\chi'}$ is to prove that $H^*_c(X_h^1, \overline{\mathbb{Q}}_\ell)[\chi]$ is a summand of $\text{Ind}_{T^1_h(\mathbb{F}_q)}^{G^1_h(\mathbb{F}_q)}(\chi)$. This is our next result.

**Theorem 6.5.2** For any $\chi : T^1_h(\mathbb{F}_q) \to \overline{\mathbb{Q}}_\ell^X$,

$$\text{Hom}_{G^1_h(\mathbb{F}_q)}\left(\text{Ind}_{T^1_h(\mathbb{F}_q)}^{G^1_h(\mathbb{F}_q)}(\chi), H^*_c(Z_h^1, \overline{\mathbb{Q}}_\ell)[\chi]\right) \neq 0.$$  

In particular, $s_{\chi} = r_{\chi}$.

The proof of Theorem 6.5.2 is essentially the same proof as [5, Theorem 6.2.4]. By Frobenius reciprocity, it is enough to show

$$\text{Hom}_{T^1_h(\mathbb{F}_q)}\left(\chi, H^*_c(X_h^1, \overline{\mathbb{Q}}_\ell)[\theta]\right) \neq 0. \quad (6.6)$$

We will sometimes write $T^1_h = T^1_{h,n,q}$ and $G^1_h = G^1_{h,n,q}$, $X^1_h = X^1_{h,n,q}$, $g^q_n$, and $s_{\chi} = s_{\chi}^{n,q}$ to emphasize the dependence on $n, q$. It is clear that once (6.6) is established, then by Theorem 6.4.1, it follows that $s_{\chi} = r_{\chi}$. We first establish two lemmas. Just for these two lemmas, we write $H^*_c(X)$ to mean $H^*_c(X, \overline{\mathbb{Q}}_\ell)$ for notational brevity.
Lemma 6.5.3 \textit{For any } \zeta \in \mathbb{F}_q^\times \text{ with trivial } \text{Gal}(\mathbb{F}_{q^n}/\mathbb{F}_q)\text{-stabilizer and any } g \in T_1^t(\mathbb{F}_q), \\
\text{Tr} \left( (\zeta, 1, g); H^\times_c( X^1_h ) \right) = (-1)^{r_x} \chi(g).

\textbf{Proof} \text{ Recall that the action of } (\zeta, 1, 1) \in \Gamma_h \text{ is given by conjugation. Observe that if } x \in (X^1_h)(\zeta, 1, 1), \text{ then } x = g_b(v_1, 0, \ldots, 0). \text{ Furthermore, this forces } v_1 \in \mathbb{W}_1^t(\mathbb{F}_{q^n}). \text{ Therefore } (X^1_h)(\zeta, 1, 1) = T_1^t(\mathbb{F}_q). \text{ By the Deligne–Lusztig fixed point formula,}

\text{Tr} \left( (\zeta, g, 1)^*; H^\times_c( X^1_h ) \right) = \frac{1}{\# T_1^t(\mathbb{F}_q)} \sum_{t \in T_1^t(\mathbb{F}_q)} \chi(t)^{-1} \text{Tr} \left( (\zeta, g, t)^*; H^\times_c( X^1_h ) \right) \\
= \frac{1}{\# T_1^t(\mathbb{F}_q)} \sum_{t \in T_1^t(\mathbb{F}_q)} \chi(t)^{-1} \text{Tr} \left( (1, g, t)^*; H^\times_c( X^1_h(\zeta, 1, 1) ) \right) \\
= \frac{1}{\# T_1^t(\mathbb{F}_q)} \sum_{t \in T_1^t(\mathbb{F}_q)} \chi(t)^{-1} \sum_{\chi' : T_1^t(\mathbb{F}_q) \to \mathbb{Q}_c^*} \chi'(g) \chi'(t) = \chi(g).

The conclusion of the lemma now follows from Corollary 6.5.1. \hfill \Box

Lemma 6.5.4 \textit{Let } p_0 \text{ be a prime dividing } n. \text{ For any } \zeta \in \mathbb{F}_{q^{p_0}}^\times \mathbb{F}_q^\times \text{ and any } g \in T_1^t(\mathbb{F}_q), \\
(-1)^{r_x} \text{Tr} \left( (\zeta, 1, g); H^\times_c( X^1_{h,n,q} ) \right) = (-1)^{r_x} \text{Tr} \left( (1, 1, g); H^\times_c( X^1_{h,n/p_0,q_0} ) \right).

\textbf{Proof} \text{ Recall that the action of } (\zeta, 1, 1) \in \Gamma_h \text{ is given by conjugation. Observe that if } x \in (X^1_h)(\zeta, 1, 1), \text{ then } x = g_b(v_1, \ldots, v_n) \text{ where } v_i = 0 \text{ for all } i \neq 1 \text{ modulo } p_0. \text{ The map}

f : (X^1_{h,n,q})(\zeta, 1, 1) \to X^1_{h,n/p_0,q_0} \\
g^n_{b,q}(v_1, v_2, \ldots, v_n) \mapsto g^{n/q_{0,p_0}}_{b}(v_1, v_{p_0+1}, v_{p0+1}, \ldots, v_{n-p_0+1})

defines an isomorphism equivariant under the action of } T_1^t(\mathbb{F}_q) \times T_1^t(\mathbb{F}_q) \cong T_1^t(\mathbb{F}_q) \times T_1^t(\mathbb{F}_q). \text{ (Note that the determinant condition on the image can be seen by observing that the rows and columns of } x := g^n_{b,q}(v_1, \ldots, v_n) \text{ can be rearranged so that the matrix becomes block-diagonal of the form diag}( f(x), \sigma^l(f(x)), \ldots, \sigma^{l(p_0-1)}(f(x))). \text{ Hence the determinant of } x \text{ is fixed by } \sigma \text{ if and only if the determinant of } f(x) \text{ is fixed by } \sigma^{p_0}.)

By the Deligne–Lusztig fixed-point formula,

\text{Tr} \left( (\zeta, g, t)^*; H^\times_c( X^1_{h,n,q} ) \right) = \text{Tr} \left( (1, g, t)^*; H^\times_c( X^1_{h,n,q} ) \right).
so that

\[
\text{Tr} \left( (\zeta, g, 1)^*; H_c^* \left( X_{h,n,q}^1 \right) [\chi] \right) = \frac{1}{\# T_1^1 (\mathbb{F}_q)} \sum_{t \in T_1^1 (\mathbb{F}_q)} \chi(t)^{-1} \text{Tr} \left( (\zeta, g, t)^*; H_c^* \left( X_{h,n,q}^1 \right) \right)
\]

\[
= \frac{1}{\# T_1^1 (\mathbb{F}_q)} \sum_{t \in T_1^1 (\mathbb{F}_q)} \chi(t)^{-1} \text{Tr} \left( (1, g, t)^*; H_c^* \left( X_{h,n,q}^1 \right) (\zeta, 1, 1) \right)
\]

\[
= \frac{1}{\# T_1^1 (\mathbb{F}_q)} \sum_{t \in T_1^1 (\mathbb{F}_q)} \chi(t)^{-1} \text{Tr} \left( (1, g, t)^*; H_c^* \left( X_{h,n/p_0,q/p_0}^1 \right) \right)
\]

\[
= \text{Tr} \left( (1, g, 1)^*; H_c^* \left( X_{h,n/p_0,q/p_0}^1 \right) \right).
\]

The conclusion of the lemma now holds by Corollary 6.5.1. □

Lemma 6.5.5 Let \( \chi : T_1^1 (\mathbb{F}_q) \to \overline{\mathbb{Q}_\ell}^\infty \). Assume that we are in one of the following cases:

1. \( n > 1 \) is odd and \( p_0 \) is a prime divisor of \( n \).
2. \( n > 1 \) is even and \( p_0 = 2 \).

Fix a \( \zeta \in \mathbb{F}_{q_0}^\times \) such that \( \langle \zeta \rangle = \mathbb{F}_{q_0}^\times \) and consider the extension of \( \chi \) defined by

\[
\tilde{\chi} : \mathbb{F}_{q_0}^\times \times T_1^1 (\mathbb{F}_q) \to \overline{\mathbb{Q}_\ell}^\infty, \quad (\zeta^i, g) \mapsto \begin{cases} \chi(g) & \text{if } q \text{ is even,} \\ (\zeta^i)^{(n/q_0 + n/p_0 q_0)} \cdot \chi(g) & \text{if } q \text{ is odd.} \end{cases}
\]

Then

\[
\sum_{x \in \mathbb{F}_{q_0}^\times \setminus \mathbb{F}_q} \tilde{\chi} (x, 1)^{-1} \neq 0.
\]

Proof This is the same proof as [5, Lemma 6.2.6]. □

Proof of Theorem 6.5.2 The proof is exactly as in [5, Theorem 6.2.4]. We give a sketch here. Since \( X_{h,1,q}^1 = T_1^1 (\mathbb{F}_q) \) and hence for any \( \chi : T_1^1 (\mathbb{F}_q) \to \overline{\mathbb{Q}_\ell}^\infty \), we have

\[
H_{c_\ell}^{X_{h,1,q}^1} (X_{h,1,q}^1) [\chi] = H_c^0 (T_1^1 (\mathbb{F}_q)) [\chi] = \chi
\]

so Eq. (6.6) holds for \( n = 1 \) and \( q \) arbitrary. We induct on the number of prime divisors of \( n \): assume that for a fixed integer \( l \geq 0 \), Eq. (6.6) holds for any \( \prod_{i=1}^l p_i \) and arbitrary \( q \), where the \( p_i \) are (possibly non-distinct) primes. We will show that Eq. (6.6) holds for any \( \prod_{i=0}^l p_i \) and arbitrary \( q \). If \( n \) is even, let \( p_0 = 2 \); otherwise, \( p_0 \) can be taken to be anything. Let \( \tilde{\chi} \) be as in Lemma 6.5.5. Then
\[ \sum_{(x, g) \in \mathbb{F}_q^* \times \mathbb{T}_1(F_q)} \bar{x}(x, g)^{-1} \text{Tr} \left( (x, 1, g); H_c^{n,q}(X_{h,n,q})|\chi| \right) \]

\[ = \#(\mathbb{F}_q^* \times \mathbb{T}_1(F_q)) \cdot \dim \text{Hom}_{\mathbb{F}_q^* \times \mathbb{T}_1(F_q)} \left( \bar{x}, H_c^{n,q}(X_{h,n,q})|\chi| \right) + \sum_{(x, g) \in \mathbb{F}_q^* \times \mathbb{T}_1(F_q), x \in \mathbb{F}_q^* \setminus \mathbb{F}_q} \bar{x}(x, g)^{-1} (-1)^{x^2 + x^{n/p_0} + p_0} \cdot \text{Tr} \left( (1, 1, g); H_c^{n/p_0,q,p_0}(X_{h,n/p_0,q,p_0})|\chi| \right). \]

By the inductive hypothesis together with Lemma 6.5.5, the second summand is a nonzero number, and hence necessarily either the left-hand side is positive or the first summand is positive. In either case, Eq. (6.6) must hold. \( \square \)

For the reader’s benefit, we summarize the discussion of this section to prove Theorem 6.1.1.

**Proof of Theorem 6.1.1** By Corollary 5.2.2, we know that \( H_c^*(X_{h}^{1, \overline{Q}_\ell})|\chi| \) is (up to sign) an irreducible \( \mathbb{G}_h^1(F_q) \)-representation. By Theorem 6.4.1, for any character \( \chi' \),

\[ \text{Hom}_{\mathbb{G}_h^1(F_q)} \left( \text{Ind}_{\mathbb{T}_1(F_q)}^{\mathbb{G}_h^1(F_q)}(\chi'), H_c^1(X_{h}^{1, \overline{Q}_\ell}) \right) \neq 0 \iff i = r_{\chi'}. \]

As explained in Corollary 6.5.1, this implies that if \( H_c^*(X_{h}^{1, \overline{Q}_\ell})|\chi| \) is a summand of \( \text{Ind}_{\mathbb{T}_1(F_q)}^{\mathbb{G}_h^1(F_q)}(\chi') \) for some \( \chi' \), then

\[ H_c^1(X_{h}^{1, \overline{Q}_\ell})|\chi| \neq 0 \iff i = r_{\chi'} = s_{\chi}. \]

By Theorem 6.5.2, we see that in fact we can take \( \chi' = \chi \), and therefore the nonvanishing cohomological degree of \( H_c^1(X_{h}^{1, \overline{Q}_\ell})|\chi| \) is in fact \( i = r_{\chi} \). The final assertion about the action of \( \text{Fr}_{q^n} \) on \( H_{cT}^*(X_{h}^{1, \overline{Q}_\ell})|\theta| = (-1)^{r_{\chi}} H_{cT}^*(X_{h}^{1, \overline{Q}_\ell})|\theta| \) now follows from Theorem 6.4.1. \( \square \)

**6.6 Dimension formula**

We use Theorem 6.1.1 to give an explicit dimension formula for the \( \mathbb{G}_h^1(F_q) \)-representation \( H_c^*(X_{h}^{1, \overline{Q}_\ell})|\chi| \).

**Corollary 6.6.1** If \( \chi : \mathbb{T}_1(F_q) \cong \mathcal{W}^1_h(F_q) \to \overline{Q}_\ell \) is any character, then

\[ \dim H_{cT}^*(X_{h}^{1, \overline{Q}_\ell})|\chi| = q^{(n^2 - n)(h-1) - nr_{\chi}/2}. \]
In particular, if $\chi$ has trivial $\text{Gal}(L/k)$-stabilizer, then
\[
\log_q \left( \dim \, H^r_{c,x}(X^1_h, \overline{Q}_\ell)[\chi] \right) = \frac{n}{2} \left( n(h_1-1)-(h_{d'}-1)-(n'-1)- \sum_{t=1}^{d'-1} \frac{m_t}{n_t}(h_t-h_{t+1}) \right).
\]

**Proof** By applying [1, Lemma 2.12] to calculate the character of $H^r_{c,x}(X^1_h, \overline{Q}_\ell)[\chi]$ at the identity, we have
\[
\dim \, H^r_{c,x}(X^1_h, \overline{Q}_\ell)[\chi] = \frac{(-1)^{r_x}}{\lambda \cdot \#T^1_h(F_q)} \sum_{t \in T^1_h(F_q)} \chi(t) \cdot #S_{1,t},
\]
where $S_{1,t} = \{ x \in X^1_h(F_q) : \sigma(Fq^n(x)) = x \cdot t \}$ and $\lambda$ is the scalar by which $\text{Fr}_q^n$ acts on $H^r_{c,x}(X^1_h, \overline{Q}_\ell)[\chi]$. Suppose that $x \in S_{1,t}$. Then by the same argument as [9, Lemma 9.3], $\det(b \sigma(g_b(x))) = t \cdot \det(b) \det(g_b(x))$, which then forces $t = 1$. By construction, $S_{1,1} = G^1_h(F_q)$, so therefore
\[
\dim \, H^r_{c,x}(X^1_h, \overline{Q}_\ell)[\chi] = \frac{\#G^1_h(F_q)}{q^{nr_x/2} \cdot \#T^1_h(F_q)} = q^{(n^2-n(h-1)-nr_x/2)},
\]
where we also use the fact that $\lambda = (-1)^{r_x} q^{nr_x/2}$ from Theorem 6.1.1. The assertion in the case that $\chi$ has trivial $\text{Gal}(L/k)$-stabilizer follows from Corollary 6.1.2. \hfill \qed

**7 Conjectures**

**7.1 Concentration in a single degree**

Recall that from Corollary 5.2.2, we know that if $\theta : T_h(F_q) \cong W^X_h(F_q^n) \to \overline{Q}_\ell^X$ is a character with trivial $\text{Gal}(F_q^n/F_{q^{n0'}})$-stabilizer, then the alternating sum $H^\ast_c(X_h \cap L^{(r)}_h \mathbb{G}^1_h, \overline{Q}_\ell)[\theta]$ is (up to sign) an irreducible $L^\ast_h(F_q) \mathbb{G}^1_h(F_q)$-representation. We conjecture that in fact these cohomology groups should be concentrated in a single degree.

**Conjecture 7.1.1** Let $r | n'$ and let $\theta : T_h(F_q) \cong W^X_h(F_q^n) \to \overline{Q}_\ell^X$ be a character with trivial $\text{Gal}(F_q^n/F_{q^{n0'}})$-stabilizer. Then there exists an integer $i_{\theta, r}$ such that
\[
H^i_c(X_h \cap L^{(r)}_h \mathbb{G}^1_h, \overline{Q}_\ell)[\theta] \neq 0 \iff i = i_{\theta, r}.
\]

In this paper, we proved this conjecture in the case $r = n'$ and in fact pinpointed the nonvanishing cohomological degree $i_{\theta, n'}$ (Theorem 6.1.1). We expect that a similar formula for $i_{\theta, r}$ is obtainable, where the methods in this paper can be used to reduce the determination of $i_{\theta, r}$ to a "depth-zero" setting. The hypotheses of Conjecture 7.1.1 should be equivalent to saying that the consequent depth-zero input comes from the $\theta_0$-isotypic part of the cohomology of a classical Deligne–Lusztig variety (of dimension
r − 1) for the twisted Levi \( L_{1,r} \) in \( G_1 \), where \( \theta_0 \) is a character of \( T_1(\mathbb{F}_q) \cong \mathbb{F}_q^\times \) in general position.

### 7.2 Relation to loop Deligne–Lusztig varieties

The varieties \( X_h \) are closely related to a conjectural construction of Deligne–Lusztig varieties for p-adic groups initiated by Lusztig [15]. We call these sets loop Deligne–Lusztig varieties, although the algebro-geometric structure is still unknown in general.

In [9], we studied this question for a certain class of these sets attached to inner forms of \( GL_n \). We prove (see also [8, Proposition 2.6]) that the fpqc-sheafification \( X \) of the presheaf on category \( \text{Perf}_{\mathbb{F}_q} \) of perfect \( \mathbb{F}_q \)-schemes

\[
X: R \mapsto \{ x \in LG(R) : x^{-1}F(x) \in LU(R) \}/L(U \cap F^{-1}U)
\]

is representable by a perfect \( \mathbb{F}_q \)-scheme and that \( X \) is the perfection of

\[
\bigsqcup_{g \in G(k)/G_{x,0}(\mathcal{O}_k)} g \cdot \lim_h X_h.
\]

We see that an intermediate step to understanding the cohomology of loop Deligne–Lusztig is to calculate the cohomology of \( X_h \).

However, for various reasons, it is often easier to calculate the cohomology of the Drinfeld stratification. For example, in [8], to prove cuspidality of \( H_\ast(X, \mathbb{Q}_\ell)[\theta] \) for a broad class of characters \( \theta: T(k) \to \mathbb{Q}_\ell^\times \), we calculate the formal degree of this representation, which we achieve by calculating the dimension of \( H_\ast^c(X_h^{(n')}, \mathbb{Q}_\ell)[\theta] \) from the Frobenius eigenvalues (see Corollary 6.6.1). In this setting, we can prove a comparison formula between the cohomology of \( X_h^{(n')} \) and the cohomology of \( X_h \) (see Section 7.2.1.2).

We conjecture the following comparison theorem between the cohomology of \( X_h \) and its Drinfeld stratification. In Sect. 7.2.1, we present evidence supporting the truth of this conjecture.

**Conjecture 7.2.1** Let \( r \mid n' \) and let \( \theta: T_h(\mathbb{F}_q) \cong \mathbb{W}_h^\times(\mathbb{F}_{q^n}) \to \mathbb{Q}_\ell^\times \) be a character with trivial \( \text{Gal}(L/k) \)-stabilizer. Let \( \chi := \theta|_{\mathbb{W}_h^1(\mathbb{F}_{q^n})} \) and assume that the stabilizer of \( \chi \) in \( \text{Gal}(L/k) \) is equal to the unique index-\( n_0r \) subgroup. Then we have an isomorphism of virtual \( \mathbb{G}_h(\mathbb{F}_q) \)-representations

\[
H_\ast^c(X_h, \mathbb{Q}_\ell)[\theta] \cong H_\ast^c(X_h^{(r)}, \mathbb{Q}_\ell)[\theta].
\]
Combining Conjectures 7.1.1 and 7.2.1 with Corollary 5.2.2, the above conjecture asserts that as elements of the Grothendieck group of $G_h(\mathbb{F}_q)$,

$$H^*_c(X_h, \mathbb{Q}_\ell)[\theta] = (-1)^{i_\theta, r} H^i_c(X_h^{(r)}, \mathbb{Q}_\ell)[\theta] = (-1)^{i_\theta, r} \text{Ind}^{G_h(\mathbb{F}_q)}_{\mathbb{Q}_\ell}[\theta] \left(H^i_c(X_h \cap X_h^{(r)}[\mathbb{Q}_\ell][\theta])\right).$$

7.2.1 Evidence

At present, we can prove Conjecture 7.2.1 in some special cases. We discuss these various cases, their context, and the ideas involved in the proof.

7.2.1.1. The most degenerate setting of Conjecture 7.2.1 is when $G$ is a division algebra over $k$. Then $n' = 1$ and so the closed Drinfeld stratum $X_h^{(1)}$ is the only Drinfeld stratum. Additionally, we have that $X_h^{(n')}$ is a disjoint union of $\# G_h(\mathbb{F}_q)$ copies of $X_h^1 := X_h \cap G_h^1$. In [5], all the technical calculations happen at the level of $X_h^1$ (though in different notation in op. cit.), and using the new methods developed there, one knows nearly everything about the representations $H^i_c(X_h^1, \mathbb{Q}_\ell)[\chi]$ for arbitrary characters $\chi : \mathbb{T}_h^1(\mathbb{F}_q) \to \mathbb{Q}_\ell^\times$. However, the expected generalization of these techniques extend not to $H^i_c(X_h, \mathbb{Q}_\ell)[\chi]$, but to $H^i_c(X_h^{(r)}, \mathbb{Q}_\ell)[\chi]$—hence one is really forced to work on the stratum in order to approach $X_h$ (at least with the current state of technology).

7.2.1.2. Now let $G$ be any inner form of $\text{GL}_n$ (as it has been this entire paper, outside Sect. 3). We are close to establishing Conjecture 7.2.1 when $\chi = \theta |_{\mathbb{W}_h^1(\mathbb{F}_q^n)}$ has trivial $\text{Gal}(L/k)$-stabilizer. In this case, Conjecture 7.2.1 says that $H^*_c(X_h, \mathbb{Q}_\ell)[\theta] \cong H^*_c(X_h^{(n')}, \mathbb{Q}_\ell)[\theta]$ as virtual $G_h(\mathbb{F}_q)$-representations. In [8, Theorem 4.1], we prove this isomorphism holds under the additional assumption that $p > n$. The idea here is to use a highly nontrivial generalization of a method of Lusztig to calculate the inner product $\langle H^*_c(X_h, \mathbb{Q}_\ell)[\theta], H^*_c(X_h^{(n')}, \mathbb{Q}_\ell)[\theta] \rangle$ in the space of conjugation-invariant functions on $G_h(\mathbb{F}_q)$.

In “Appendix A”, we present a possible geometric approach to Conjecture 7.2.1 which has its roots in the $\text{GL}_2$ setting of the proof of [14, Theorem 3.5]. The idea is to study the fibers of the natural projection $\pi : X_h \to X_h^{-1}$. We can show that the behavior of $\pi^{-1}(x)$ depends only on the location of $x$ relative to the Drinfeld stratification of $X_h$: If $r$ is the smallest divisor of $n'$ such that $x \in X_h^{(r)}$ (i.e. $x$ is in the $r$th Drinfeld stratum $X_h^{(r)}$ of $X_h$), then there exists a morphism

$$\pi^{-1}(x) \to \bigsqcup_{\mathbb{W}_h^{-1}(\mathbb{F}_q^{n\theta})} \mathbb{A}^{n-1}$$

which is a composition of isomorphisms and purely inseparable morphisms. Moreover, the action of $\ker(\mathbb{W}_h^{-1}(\mathbb{F}_q^{n\theta}) \to \mathbb{W}_h^{-1}(\mathbb{F}_q^{n\theta}))$ on $\pi^{-1}(x)$ fixes the set of connected

\[2\text{ When } G = \text{GL}_n, \text{ then this is literally what we do in "Appendix A". When } G \text{ is a nonsplit inner form of } \text{GL}_n, \text{ in order to get a shape analogous to the split case, we work with an auxiliary scheme which is an affine fibration over } X_h.\]
components. The crucial point here is that the fibers of the natural map
\[
X_{h,r} / \ker \left( \mathbb{V}^{h-1}_h (\mathbb{F}_q^n) \to \mathbb{V}^{h-1}_h (\mathbb{F}_{q^{n/(n_0r)}}) \right) \to X_{h-1,r}
\]
are again isomorphic to \( \bigsqcup \mathbb{V}^{h-1}_h (\mathbb{F}_q^{n_0r}) \mathbb{A}^{n-1} \) and therefore \( \ker(\mathbb{V}^{h-1}_h (\mathbb{F}_q^n) \to \mathbb{V}^{h-1}_h (\mathbb{F}_{q^{n/(n_0r)}})) \) acts trivially on the cohomology of \( X_{h,r} \):
\[
H^*_c (X_{h,r}, \overline{\mathcal{O}_\ell}) \cong H^*_c (X_{h,r}, \overline{\mathcal{O}_\ell})^{\ker(\mathbb{V}^{h-1}_h (\mathbb{F}_q^n) \to \mathbb{V}^{h-1}_h (\mathbb{F}_{q^{n/(n_0r)}}))}.
\]

Using open/closed decompositions of \( X_h \) via Drinfeld strata, we have that if \( \theta \) is trivial on \( \ker(\mathbb{V}^{h-1}_h (\mathbb{F}_q^n) \to \mathbb{V}^{h-1}_h (\mathbb{F}_{q^{n/(n_0r)}})) \), then
\[
H^*_c (X_h, \overline{\mathcal{O}_\ell})[\theta] \cong H^*_c (X_h^{(r)}, \overline{\mathcal{O}_\ell})[\theta]
\]
as virtual \( \mathbb{G}_h (\mathbb{F}_q) \)-representations. It seems reasonable to guess that if one can generalize “Appendix A” to study the fibers of \( X_h \to X_1 \), then one could establish Conjecture 7.2.1 using a similar reasoning as above.

Acknowledgements We would like to thank Masao Oi and Michael Rapoport for enlightening conversations. Additionally we’d like to thank the anonymous referees for their comments and advice which have greatly improved the exposition of this paper. The first author was partially supported by the DFG via the Leibniz Prize of Peter Scholze and an NSF Postdoctoral Research Fellowship, Award No. 1802905. The second author was supported by the DFG via the Leibniz Preis of Peter Scholze.

Appendix A. The geometry of the fibers of projection maps

In this section, we study the fibers of the projection maps \( X_h \to X_{h-1} \). This is a technical computation which we perform by first using the isomorphism \( X_h \cong X_h (b, b_{\text{cox}}) \) for a particular choice of \( b \) which we call the special representative. This is the first time in this paper that we see the convenience of having the alternative presentations of \( X_h \) discussed in Sects. 3.2 and 4.5.

A.1 The special representative

We first recall the content of Sect. 4.5 in the context of a particular representative of the \( \sigma \)-conjugacy class corresponding to the fixed integer \( \kappa \).

Definition A.1.1 The special representative \( b_{\text{sp}} \) attached to \( \kappa \) is the block-diagonal matrix of size \( n \times n \) with \( (n_0 \times n_0) \)-blocks of the form
\[
\left( \begin{array}{cc} 0 & \sigma \\ 1_{n_0-1} & 0 \end{array} \right)^\kappa.
\]

By [9, Lemma 5.6], there exists a \( g_0 \in G_{x,0}(\mathcal{O}_\kappa) \) such that \( b_{\text{sp}} = g_0 b_{\text{cox}} \sigma(g_0)^{-1} \). Observe further that since \( b_{\text{sp}}, b_{\text{cox}} \) are \( \sigma \)-fixed and \( b^n_{\text{sp}} = b^n_{\text{cox}} = \sigma^{kn} \),
\[
\sigma^n(g_0) = g_0.
\]
Therefore \( b_{sp} \) satisfies the conditions of Lemma 4.5.3. Recall from Sect. 4.5 that we have

\[
X_h \cong X_h(b_{sp}, b_{cox}) \cong \{ v \in \mathcal{L}_h : \sigma(\det g_{b_{sp}}(v)) = (-1)^{n-1} \det g_{b_{sp}}(v) \in \mathbb{W}_h^X \},
\]

where

\[
\mathcal{L}_h = (\mathbb{W}_h \oplus (V \mathbb{W}_{h-1})^{\otimes n_0 - 1})^{\otimes n'} \subset \mathbb{W}_h^{\otimes n}
\]

\[
g_{b_{sp}}(v) = (v_1 | v_2 | v_3 | \cdots | v_n)
\]

where \( v_i = H_{W}^{L} \cdot (b_{sp})_{(i-1)/n_0} (v) \) for \( 1 \leq i \leq n - 1 \).

In this section, we will work with

\[
X_h^+ := \{ v \in \mathcal{L}_h^+ : \sigma(\det g_{b_{sp}}(v)) = \det g_{b_{sp}}(v) \in \mathbb{W}_h^{\otimes n} \} \tag{A.2}
\]

where \( \mathcal{L}_h^+ \) is now the subquotient of \( \mathbb{W}_h^{\otimes n}_{h+1} \)

\[
\mathcal{L}_h^+ := (\mathbb{W}_h \oplus (V \mathbb{W}_h)^{\otimes n_0 - 1})^{\otimes n'},
\]

and \( g_{b_{sp}}(v) \) is defined as before. Note that (A.1) differs from (A.2) in that the former takes place in \( G_{X,0}/G_{X, (h-1)+} \) and the latter takes place in \( G_{X,0}/G_{X,h} \). A straightforward computation shows that the defining equation of \( X_h^+ \) does not depend on the quotient \( \mathcal{L}_h^+ / \mathcal{L}_h = \mathbb{A}^{n-n'} \).

Observe that \( \det g_{b_{sp}}(\zeta v) = \text{Nm}(\zeta) \cdot \det g_{b_{sp}}(\zeta v) \) where \( \text{Nm}(\zeta) = \zeta \cdot \sigma(\zeta) \cdot \sigma^2(\zeta) \cdots \sigma^{n-1}(\zeta) \). Picking any \( \zeta \) such that \( \sigma(\text{Nm}(\zeta)) = (-1)^{n-1} \text{Nm}(\zeta) \) allows us to undo the \( (-1)^{n-1} \) factor in the defining equation in (A.1). In particular, this means

\[
H^i_c(X_h^+, \mathbb{Q}_\ell) = H^{i+2(n-n')}_c(X_h, \mathbb{Q}_\ell), \quad \text{for all } i \geq 0.
\]

For each divisor \( r \mid n' \), we define the \( r \)th Drinfeld stratum \( X_{h,r}^+ \) of \( X_h^+ \) to be the preimage of \( X_{h,r} \) under the natural surjection \( X_h^+ \to X_h \).

### A.2 Fibers of \( X_{h,r}^+ \to X_{h-1,r}^+ \)

For notational convenience, we write \( b = b_{sp} \). We may identify \( \mathcal{L}_h^+ = \mathbb{A}^{n(h-1)} \) with coordinates \( x = \{ x_{i,j} \}_{1 \leq i \leq n, 0 \leq j \leq h-1} \) which we typically write as \( x = (\bar{x}, x_{1,h-1}, x_{2,h-1}, \ldots, x_{n,h-1}) \in \mathcal{L}_h^+ \times \mathbb{A}^n \); here, an element \( v = (v_1, \ldots, v_n) \in \mathcal{L}_h^+ \) is such that \( v_i = [x_{i,0}, x_{i,1}, \ldots, x_{i,n}] \) if \( i \equiv 1 \pmod{n_0} \) and \( v_i = [0, x_{i,1}, x_{i,2}, \ldots, x_{i,n}] \) if \( i \not\equiv 1 \pmod{n_0} \).

In this section, fix a divisor \( r \mid n' \). From the definitions, \( X_{h,r}^+ \) can be viewed as the subvariety of \( X_{h-1,r}^+ \times \mathbb{A}^n \) cut out by the equation

\[
0 = P_0(x)^d - P_0(x),
\]
where \( P_0 \) is the coefficient of \( \varpi h^{-1} \) in the expression \( \det g_b^{\text{red}}(v) \). Let \( c \) denote the polynomial consisting of the terms of \( P_0(x) \) which only depend on \( \tilde{x} \). An explicit calculation shows that there exists a polynomial \( P_1 \) in \( x \) such that

\[
P_0(x) = c(\tilde{x}) + \sum_{i=0}^{n_0-1} P_1(x)q^i. \tag{A.3}
\]

Therefore \( X_{h,r}^+ \) is the subvariety of \( X_{h-1,r}^+ \times \mathbb{A}^n \) cut out by

\[
P_1(x)q^{n_0} - P_1(x) = c(\tilde{x}) - c(\tilde{x})^q.
\]

One can calculate \( P_1 \) explicitly (see [9, Proposition 7.5]):

**Lemma A.2.1** Explicitly, the polynomial \( P_1 \) is

\[
P_1(x) = \sum_{1 \leq i, j \leq n'} m_{ji} x_1^{q(j-1)n_0} (j-1)^{i-1},
\]

where \( m := (m_{ji})_{j,i} \) is the adjoint matrix of \( g_b(\tilde{x}) \) and \( \tilde{x} \) denotes the image of \( x \) in \( \tilde{V} = \mathcal{L}_0/\mathcal{L}_0^{(1)} \). Explicitly, \( m_{ji} g_b(\tilde{x}) = \det g_b(\tilde{x}) \) and the \((j, i)\)th entry of \( m \) is \((-1)^{i+j} \) times the determinant of the \((n'-1) \times (n'-1) \) matrix obtained from \( g_b(\tilde{x}) \) by deleting the \( i \)th row and \( j \)th column.

The main result of this section is:

**Proposition A.2.2** There exists an \( X_{h-1,r}^+ \)-morphism

\[
M_r : X_{h-1,r}^+ \times \mathbb{A}^n \rightarrow X_{h-1,r}^+ \times \mathbb{A}^n
\]

(the left \( \mathbb{A}^n \) in terms of the coordinates \( \{x_i, h-1\}_{i=1}^n \) and the right \( \mathbb{A}^n \) in terms of new coordinates \( \{z_i\}_{i=1}^n \)) satisfying the following properties:

(i) \( M_r \) is a composition of \( X_{h-1,r}^+ \)-isomorphisms and purely inseparable \( X_{h-1,r}^+ \)-morphisms.

(ii) \( M_r(X_{h,r}^+) \) is the closed subscheme defined by the equation

\[
z_1^{q^{n_0}} - z_1 = c(\tilde{x}) - c(\tilde{x})^q,
\]

where \( c \) is as in (A.3).

(iii) \( M_r \) is \( \mathbb{W}_h^{-1}(\mathbb{F}_q^n) \)-equivariant after equipping the left \( X_{h-1,r}^+ \times \mathbb{A}^n \) with the \( \mathbb{W}_h^{-1}(\mathbb{F}_q^n) \)-action

\[
1 + \varpi h^{-1} a : x_i, h-1 \mapsto x_i, h-1 + x_i, 0 a, \quad \text{for all } 1 \leq i \leq n,
\]
and the right $X^+_{h-1,r} \times \mathbb{A}^n$ with the $W^h_{h-1}(\mathbb{F}_q)$-action

$$1 + \sigma^h a : z_i \mapsto \begin{cases} z_1 + \text{Tr}_{\mathbb{F}_q^n/\mathbb{F}_q} (a) & \text{if } i = 1, \\ z_2 + a & \text{if } r \neq n' \text{ and } i = 2, \\ z_i & \text{otherwise}. \end{cases}$$

In the rest of this section we prove Proposition A.2.2. To simplify the notation we will first establish the proposition in the case $\kappa = 0$ (i.e. $G = \text{GL}_n$), and at the end generalize it to all $\kappa$. The first part of the proof of Proposition A.2.2 is given by the lemma below. Before stating it, we establish some notation. For an ordered basis $B$ of $V$ and $v \in V$, let $v_B$ denote the coordinate vector of $v$ in the basis $B$. For two ordered bases $B, C = \{c_i\}_{i=1}^n$ of $V$, let $M_{B,C}$ denote the base change matrix between them, that is, the $i$th column vector of $M_{B,C}$ is $c_i$. It is clear that

- $M_{C,B} = M_{B,C}^{-1}$,
- for any $v \in V$, $M_{B,C}v_C = v_B$,
- for a third ordered basis $D$ of $V$, one has $M_{B,C}M_{C,D} = M_{B,D}$.

For a linear map $f : V \to V$, let $M_{B,C}(f)$ denote the matrix representation of $f$; that is, $M_{B,C}(f) \cdot v_C = f(v)_B$. In $V$ we have the two ordered bases:

$\mathcal{E} :=$ the standard basis of $V$, arising from the basis $\{e_i\}$ of the lattice $\mathcal{L}_0$,
$\mathcal{B}_x := \{\sigma^{-1}_n(x)\}_{i=1}^n$, attached to the given $x \in X^+_{0}$.

We identify $V$ with $\overline{\mathbb{F}}_q^n$ via the standard basis $\mathcal{E}$ and write $v = v_\mathcal{E}$ for all $v \in V$.

**Lemma A.2.3** Assume $\kappa = 0$. There exists an $X^+_{h-1,r}$-isomorphism $X^+_{h-1,r} \times \mathbb{A}^n \sim X^+_{h-1,r} \times \mathbb{A}^n$ given by a linear change of variables $x_{i,h-1} \rightsquigarrow x'_{i,h-1}$, such that $P_1$ in the new coordinates takes the form

$$P_1 = x'_{1,h-1} + x'_{1,h-1}q + \cdots + x'_{1,h-1}q^{n-1} + \sum_{j=0}^{s} \sum_{i=j+1}^{i+j+1} x'_{s+i,h-1},$$

and the action of $1 + \sigma^h a \in W^h_{h-1}(\mathbb{F}_q)$ on the coordinates $x'_{i,h-1}$ is given by

$$x'_{i,h-1} \mapsto \begin{cases} x'_{i,h-1} + a & \text{if } i = 1, \\ x_{i,h-1} & \text{if } i \geq 2. \end{cases} \quad (A.4)$$

**Proof of Lemma A.2.3** We have to find a morphism $C := (c_{ij}) : X^+_{h-1,r} \to \text{GL}(V) = \text{GL}_n(\mathbb{F}_q)$ (this identification uses the standard basis $\mathcal{E}$ of $V$) such that the corresponding linear change of coordinates

$$x_{i,h-1} = c_{1,1}x'_{1,h-1} + c_{1,2}x'_{2,h-1} + \cdots + c_{i,n}x'_{n,h-1}, \quad \text{for all } 1 \leq i \leq n. \quad (A.5)$$
brings $P_1$ to the requested form. Moreover, it suffices to do this fiber-wise by first determining $C(\tilde{x})$ for any point $\tilde{x} \in X^+_{h^{-1}, r}$ and then seeing that $\tilde{x} \mapsto C(\tilde{x})$ is in fact an algebraic morphism.

Fix $\tilde{x} \in X^+_{h^{-1}, r}$ with image $x \in X^+$, and write $C$ instead of $C(\tilde{x})$ to simplify notation. Let $C_i$ denote the $i$th column of $C$. Our coordinate change replaces $P_1$ by the polynomial (after dividing by the irrelevant non-zero constant $\det g_b(x) \in \mathbb{P}^n_q$)

\[
P_1 = x_{1,h^{-1}}^i(m_1 \cdot C_1) + x_{1,h^{-1}}^i(m_2 \cdot \sigma_b(C_1)) + x_{1,h^{-1}}^i(m_3 \cdot \sigma_b^2(C_1)) + \cdots + x_{1,h^{-1}}^i(m_n \cdot \sigma_b^{n-1}(C_1)) + x_{2,h^{-1}}^i(m_1 \cdot C_2) + x_{2,h^{-1}}^i(m_2 \cdot \sigma_b(C_2)) + x_{2,h^{-1}}^i(m_3 \cdot \sigma_b^2(C_2)) + \cdots + x_{2,h^{-1}}^i(m_n \cdot \sigma_b^{n-1}(C_2)) + \cdots + x_{n,h^{-1}}^i(m_1 \cdot C_n) + x_{n,h^{-1}}^i(m_2 \cdot \sigma_b(C_n)) + x_{n,h^{-1}}^i(m_3 \cdot \sigma_b^2(C_n)) + \cdots + x_{n,h^{-1}}^i(m_n \cdot \sigma_b^{n-1}(C_n))
\]

in the indeterminates $\{x_{i,h^{-1}}^i\}_{i=1}^n$. Here, we write $m_i$ to mean the $i$th row of the matrix $m$ (adjoint to $g_b(x)$) from Lemma A.2.1. For $z \in V$, we put

\[
m \ast z = \sum_{i=1}^n (m_i \cdot (b\sigma)^{i-1}(z))e_i.
\]

The intermediate goal is to describe the map $m \ast : V \rightarrow V$ in terms of a coordinate matrix. Of course, $m \ast$ is not linear, but its composition with the projection on the $i$th component (corresponding to the $i$th standard basis vector) is $\sigma^{i-1}$-linear. Thus we instead will describe the linear map $(m \ast)' : V \rightarrow V$, which is the composition of $m \ast$ and the map $\sum_i v_i e_i \mapsto \sum_i \sigma^{-(i-1)}(v_i)e_i$. This is done by the following lemma.

**Lemma A.2.4** Assume $\kappa = 0$. We have

\[
M_{\mathcal{G}, \mathcal{G}}(\mathcal{A}_\varepsilon)((m \ast)') = \begin{pmatrix}
1 & 0 & 0 & \cdots & 0 & 0 \\
1 & 0 & 0 & \cdots & 0 & \sigma^{-1}(y_1) \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\
1 & 0 & 0 & \cdots & \star & \star \\
1 & \sigma^{-(n-2)}(y_{n-2}) & \cdots & \vdots & \star & \star \\
1 & \sigma^{-(n-1)}(y_{n-1}) & \star & \cdots & \star & \star \\
\end{pmatrix}
\]

where the $y_i$’s are defined by the equation

\[
(b\sigma)^n(v) = v + \sum_{i=1}^{n-1} y_i(b\sigma)^i(v).
\]
More precisely, if $\mu_{i,j}$ denotes the $(i, j)$th entry of $\det(g_b(\bar{x}))^{-1}M_{\mathcal{E}, \mathcal{B}_x}((m*)')$, then for $1 \leq i, j \leq n$ we have

$$
\mu_{i,j} = \begin{cases} 
1 & \text{if } j = 1 \\
0 & \text{if } i + j \leq n + 1 \text{ and } j > 1 \\
\sigma^{-(i-1)}(y_{i-1}) & \text{if } i + j = n + 2 \\
\mu_{i-1,j} + \sigma^{-(i-1)}(y_{i-1})\sigma^{n-(i-1)}(\mu_{n,j+i-(n+1)}) & \text{if } i + j \geq n + 3 \text{ and } i \geq 3.
\end{cases}
$$

In particular, if $i + j \geq n + 3$ and $y_{i-1} = 0$, then $\mu_{i,j} = \mu_{i-1,j}$.

**Proof of Lemma A.2.4** Let $z = \sum_{i=1}^{n} z_i (b\sigma)^{i-1}(x)$ be a generic element of $V$, written in $\mathcal{B}_x$-coordinates, that is $z\mathcal{B}_x$ is the $n$-tuple $(z_i)_{i=1}^{n}$. The $(i, j)$th entry of $M_{\mathcal{E}, \mathcal{B}_x}((m*)')$ is equal to $\sigma^{-(i-1)}$ applied to the coefficient of $\sigma^{i-1}(z_j)$ in the $i$th entry of $(b\sigma)^{i-1}(z)\mathcal{B}_x$ (= the $i$th entry of $m \ast z$).

The coordinate matrix of the $\sigma$-linear operator $b\sigma : V \to V$ in the basis $\mathcal{B}_x$,

$$
M_{\mathcal{B}_x, \mathcal{B}_x}(b\sigma) = \begin{pmatrix}
0 & 0 & \cdots & 0 & 1 \\
1 & 0 & \cdots & 0 & y_1 \\
0 & 1 & \cdots & 0 & y_2 \\
\vdots & \ddots & \ddots & \ddots & \vdots \\
0 & \cdots & 0 & 1 & y_{n-1}
\end{pmatrix},
$$

That is, for any $z \in V$,

$$
b\sigma(z)\mathcal{B}_x = M_{\mathcal{B}_x, \mathcal{B}_x}(b\sigma) \cdot \sigma(z)\mathcal{B}_x, \quad (A.8)
$$

where the last $\sigma$ is applied entry-wise. Explicitly, the first entry of $b\sigma(z)\mathcal{B}_x$ is $\sigma(z_n)$, and for $2 \leq i \leq n$ the $i$th entry of $b\sigma(z)\mathcal{B}_x$ is $\sigma(z_{i-1}) + y_{i-1}\sigma(z_n)$. This allows to iteratively compute $b\sigma^j(z)$ for all $i$, which we do to finish the proof.

First, we see that $z_1$ can occur in the $n$th (i.e. last) entry of $(b\sigma)^{\lambda-1}(z)\mathcal{B}_x$ only if $\lambda \geq n$; hence its contribution to the $i$th entry of $(b\sigma)^{i-1}(z)\mathcal{B}_x$ for $i \leq n$ is simply $\sigma^{i-1}(z_1)$. This shows that the first column of $M_{\mathcal{E}, \mathcal{B}_x}((m*)')$ consists of 1’s. Assume now $j \geq 2$. Then there is a smallest (if any) $i_0$ such that $z_{j}$ occurs in the $i_0$th entry of $(b\sigma)^{i_0-1}(z)\mathcal{B}_x$. Note that as $j \geq 2$, one has $i_0 \geq 2$. Then $z_j$ must have been occurred in the $n$th entry of $(b\sigma)^{i_0-2}(z)\mathcal{B}_x$. As $z_j$ occurs in $z\mathcal{B}_x$ exactly the $j$th entry, and it needs $(n - j)$ times to apply $b\sigma$ to get it to the $n$th entry, we must have $i_0 - 2 \geq n - j$. This shows that the $(i, j)$th entry of $M_{\mathcal{E}, \mathcal{B}_x}((m*)')$ is 0, unless $i \geq n + 2 - j$. The same consideration shows that if $i = n + 2 - j$, then $\sigma^{i-1}(z_j)$ has the coefficient $y_{i-1}$ in $\sigma^{i-1}_b(z)\mathcal{B}_x$. This gives the entries of $M_{\mathcal{E}, \mathcal{B}_x}((m*)')$ on the diagonal $i = n + 2 - j$.

It remains to compute the entries below it, so assume $i > n + 2 - j$. Again, by the characterization of the entries of $M_{\mathcal{E}, \mathcal{B}_x}((m*)')$ in the beginning of the proof and by the explicit description of how $\sigma_b$ acts (in the $\mathcal{B}_x$-coordinates), it is clear that the $(i, j)$th entry of $M_{\mathcal{E}, \mathcal{B}_x}((m*)')$ is just the sum of the $(i - 1, j)$th entry and $\sigma^{-(i-1)}(y_{i-1})\sigma^{n-(i-1)}((n, j - 1)$th entry). This finishes the proof of Lemma A.2.4."
Now we continue the proof of Lemma A.2.3. Let $\mathcal{C}$ denote the ordered basis of $V$ consisting of columns $C_1, C_2, \ldots, C_n$ of $C$. We have $M_{\mathcal{B}_x, \mathcal{C}} = (\det g_p(x))^{-1} m \cdot C$. In particular, to give the invertible matrix $C$ it is equivalent to give the invertible matrix $M_{\mathcal{B}_x, \mathcal{C}}$. But the $i$th column of $M_{\mathcal{B}_x, \mathcal{C}}$ is the coordinate vector of $C_i$ in the basis $\mathcal{B}_x$, i.e., what we denoted $C_i, \mathcal{B}_x$. We now show that one can find an invertible $M_{\mathcal{B}_x, \mathcal{C}}$, such that for its columns $C_i, \mathcal{B}_x$ we have

$$m \cdot C_{1, \mathcal{B}_x} = \sum_{\lambda=1}^{n} e_\lambda$$
$$m \cdot C_{s+2-j, \mathcal{B}_x} = \sum_{\lambda=i_j+1}^{i_j} e_\lambda \quad \text{for } s \geq j \geq 0,$$
$$m \cdot C_{j', \mathcal{B}_x} = 0 \quad \text{if } j' > s + 2. \quad (A.9)$$

Taking into account Eq. (A.6) and the definition of $m \ast$ in (A.7), this (plus the fact that $x \mapsto M_{\mathcal{B}_x, \mathcal{C}}$ will in fact an algebraic morphism) finishes the proof of Lemma A.2.3, except for the claim regarding the $W_h^{h^{-1}(\mathbb{F}_q^n)}$-action.

To find $M_{\mathcal{B}_x, \mathcal{C}}$ satisfying (A.9), first observe that by Lemma A.2.4, there is some invertible matrix $S$ depending on $\bar{x} \in X_{h^{-1}, r}^+$ (in fact, only on its image $x \in X_1^+$), such that $M_{\mathcal{E}, \mathcal{B}_x}((m \ast)^') \cdot S$ has the following form: its first column consists of 1’s; its $i$th column is 0, unless $i = n + 1 - i_j$ for some $s \geq j \geq 0$; for $s \geq j \geq 0$, the $\lambda$th entry of its $(n + 1 - i_j)$th column is 1 if $i_j + 1 \leq \lambda \leq i_{j+1}$ (we put $i_{s+1} := n$ here) and zero otherwise. (To show this, use the general shape of $M_{\mathcal{E}, \mathcal{B}_x}((m \ast)^')$ provided by Lemma A.2.4, and then consecutively apply row operations to it and use the last statement of Lemma A.2.4). Moreover, it is also clear from Lemma A.2.4 that $S$ will be upper triangular with the upper left entry $= 1$.

Secondly, let $T$ be a matrix such that: the first row has 1 in the first position and zeros otherwise; all except for the first entry of the first column are 0; for $s \geq j \geq 0$, the $(n + 1 - i_j)$th row has 1 in the $(s + 2 - j)$th position and 0’s otherwise; the remaining rows can be chosen arbitrarily. Obviously, $T$ can be chosen to be a permutation matrix with entries only 0 or 1, and in particular invertible and independent of $x$. Finally, put $M_{\mathcal{B}_x, \mathcal{C}} := S \cdot T$. Explicitly the columns of the matrix

$$M_{\mathcal{E}, \mathcal{B}_x}((m \ast)^') \cdot M_{\mathcal{B}_x, \mathcal{C}} = (M_{\mathcal{E}, \mathcal{B}_x}((m \ast)^') \cdot S) \cdot T \quad (A.10)$$

are as follows: the first column consist of 1’s; for $s \geq j \geq 0$, the the $\lambda$th entry of the $(s + 2 - j)$th column is 1 if $i_j + 1 \leq \lambda \leq i_{j+1}$, and zero otherwise; all other columns consist of 0’s. On the other side, the $j$th column of of $M_{\mathcal{E}, \mathcal{B}_x}((m \ast)^') \cdot M_{\mathcal{B}_x, \mathcal{C}}$ is precisely $m \ast C_{j, \mathcal{B}_x}$ (up to the unessential $\sigma^{-r}$-twist in each entry). This justifies (A.9).

The action of $1 + \sigma^h a \in W_h^{h^{-1}(\mathbb{F}_q^n)}$ on the coordinates $x_{i, h}$ is given by $(x_{i, h})_{i=1}^{n} \mapsto (x_{i, h} + ax_{i, 0})_{i=1}^{n}$. We determine the action $1 + \sigma^h a$ in the coordinates $x_{i, h}'$. Indeed,
let $C^{-1} = (d_{i,j})_{1 \leq i,j \leq n}$. Then $1 + \sigma_h a$ acts on $x'_{i,h}$ by

$$x'_{i,h} = \sum_{j=1}^{n} d_{i,j} x_{j,h} \mapsto \sum_{j=1}^{n} d_{i,j} (x_{j,h} + ax_{j,0}) = x'_{i,h} + a \sum_{j=1}^{n} d_{i,j} x_{j,0}.$$ 

Organizing the $x_{i,h}$ for $1 \leq i \leq n$ in one (column) vector, we can rewrite this as

$$1 + \sigma_h a : (x'_{i,h})_{i=1}^{n} \mapsto (x'_{i,h})_{i=1}^{n} + aC^{-1} \cdot x.$$ 

We determine $C^{-1} \cdot x$. As $M_{B_{\kappa},C} = \text{det}(gb(x))^{-1} m C = gb(x)^{-1} C$ (as $\text{det}(gb(x))^{-1} m = gb(x)^{-1}$), we have $C^{-1} = M_{B_{\kappa},C}^{-1} gb(x)^{-1}$. But $x$ is the first column of $gb(x)$, thus

$$C^{-1} \cdot x = M_{B_{\kappa},C}^{-1} gb(x)^{-1} \cdot x = M_{B_{\kappa},C}^{-1} \cdot (1, 0, \ldots, 0)^T,$$

so $C^{-1} \cdot x$ is the first column of $M_{B_{\kappa},C}^{-1} = (ST)^{-1} = T^{-1} S^{-1}$. But $S$ is upper triangular with upper left entry $= 1$, so the first column of $M_{B_{\kappa},C}^{-1}$ is the first column of $T^{-1}$, which is $(1, 0, \ldots, 0)^T$. This finishes the proof of the lemma. 

The second part of the proof is given by the following lemma.

**Lemma A.2.5** Assume $\kappa = 0$. There exists a $X_{h,1,r}^+$-morphism $X_{h,1,r}^+ \times \mathbb{A}^n \to X_{h,1,r}^+ \times \mathbb{A}^n$ such that if $\{z_i\}$ denotes the coordinates on $\mathbb{A}^n$ on the target $\mathbb{A}^n$, then the image of $X_{h,r}^+$ in $X_{h,1,r}^+ \times \mathbb{A}^n$ and the action of $\mathbb{W}_{h,1,0}(\mathbb{F}_q)$ on $z_i$ are given by Proposition A.2.2(ii),(iii). Moreover, such a morphism is given by the composition of the change-of-variables $x'_{i,h}$ and purely inseparable morphisms of the form $x'_{i,h-1} \mapsto x'_{i,q^{-j}}$ for appropriate $i, j$.

**Proof** If $r = n$, this is literally Lemma A.2.3. Assume $r < n$. First, for $s \geq j \geq 0$, replace $x'_{s+2-j}$ by $x'_{s+2-j}^{r,q}$. Then, by applying a series of iterated changes of variables of the form $x'_c = x'_c + x'_d^{r,q^{\lambda}}$ for appropriate $2 \leq c, d \leq s + 2$ and $\lambda$ (essentially following the Euclidean algorithm to find the gcd of the integers $(i_{j+1} - i_j)$ (this gcd is equal to $r$)), we transform $P_1$ from Lemma A.2.3 to the form

$$P_1 = \sum_{i=0}^{n-1} x'_{i,h} + \sum_{i=0}^{r-1} x'_{2,i,h}.$$ 

As these operations does not involve $x'_{1,h}$, the formulas (A.4) remain true. Now make the change of variables given by $z_1 := x'_{2,h} + \sum_{j=0}^{n-1} x'_{1,h}^{r,q^j}$ and $z_2 := x'_{1,h-1}$. In this coordinates, $P_1 = \sum_{i=0}^{n-1} z'_{i}^{r,q^i}$ and the action is as claimed. 

We are now ready to complete the proof of Proposition A.2.2.
Proof of Proposition A.2.2 Combining Lemmas A.2.3 and A.2.5 we obtain Proposition A.2.2 in the case $\kappa = 0$. Now let $\kappa$ be arbitrary. It is clear that the proof of Lemma A.2.3 can be applied to this more general situation. One then obtains the same statement, with the only difference being that now our change of variables does not affect the variables $x_{i, h^{-1}}$ for $i \not\equiv 1 \mod n_0$ (these are exactly the variables which do not show up in $P_1$). That is, the right-hand side $X_{h^{-1}, r}^+ \times \mathbb{A}^n$ will have the coordinates

$$
\{ x'_{i, h^{-1}}, x^{i, q_{n_0}^{n_0-1}}_{1, h^{-1}} + \cdots + x^{i, q_{n_0}^0}_{1, h^{-1}} + \sum_{j=0}^{s} \sum_{\lambda=i_j+1} \ s_{i_j+1-j, h^{-1}},
$$

and the $W_h^{-1}(\mathbb{P}^q)$-action is given by

$$
1 + \varpi^{h^{-1}} a : x'_{i, h^{-1}} \mapsto \begin{cases}
  x'_{i, h^{-1}} + a & \text{if } i \equiv 1 \mod n_0 \text{ and } i > 1 \\
  x'_{i, h^{-1}} & \text{if } i \equiv 1 \mod n_0 \\
  x_{i, h^{-1}} + x_{i, 0} a & \text{if } i \not\equiv 1 \mod n_0.
\end{cases}
$$

We now apply the change of variables replacing $x_{i, h^{-1}}$ by $x'_{i, h^{-1}} := x_{i, h^{-1}} - x_{i, 0} x_{1, h^{-1}}$ for all $i \not\equiv 1 \mod n_0$. This exactly gives us Lemma A.2.3 for arbitrary $\kappa$ (the only difference being the $q_{n_0}$-powers occurring in $P_1$). Now Lemma A.2.5 can be applied as in the case $\kappa = 0$, and this finishes the proof of Proposition A.2.2.
