Institute of Physics, Budafoki út 8. F., H-1521 Budapest, Hungary

A generalization of the recently discovered cooperative internal conversion process (CICP) is investigated theoretically. In the cooperative internal conversion process by proton exchange investigated the coupling of bound-free electron and proton transitions due to the dipole term of their Coulomb interaction permits cooperation of two nuclei leading to proton exchange and an electron emission. General expression of the cross section of the process obtained in the one particle spherical nuclear shell model is presented. As a numerical example the cooperative internal conversion process by proton exchange in Al is dealt with. As a further generalization, cooperative internal conversion process by heavy charged particle exchange and as an example of it the cooperative internal conversion process by triton exchange is discussed. The process is also connected to the field of nuclear waste disposal.

Keywords: internal conversion and extranuclear effects, other topics of nuclear reactions: specific reactions, radioactive wastes, waste disposal

In this work the process (see Fig. 1) a bound proton of an atomic nucleus $\left(\frac{A_1}{Z_1} X, \text{particle 2} \right)$ is virtually excited into a free state (particle 3) due to the dipole term $V_{C\mu}^{dp}$ of its Coulomb-interaction (in electric dipole coupling the proton has effective charge $q_p = (1 - Z_1/A_1) e$ [4]) with one of the bound atomic electrons ($e_1$) of the atom containing the $\frac{A_1}{Z_1} X$ nucleus while the electron becomes free ($e'_1$). The free, virtual proton is captured by another nucleus $\frac{A_2}{Z_2} Y$ (particle 4) due to its nuclear potential $V_{\text{nl}}$ (created by strong interaction) forming the nucleus $\frac{A_2+1}{Z_2+1} W$ (particle 5) in this way. The sum of the rest energies of the initial nuclei is $E_{0i}$ and the sum of the the rest energies of the final nuclei is $E_{0f}$. If $E_{0i} - E_{0f} = \Delta > 0$, i.e. if $E_{0i} > E_{0f}$, then the process is energetically allowed and proton exchange is possible. The nuclear energy differ-

ence $\Delta$, which is the reaction energy, is shared between the kinetic energies of the final, free electron and the two final nuclei $[\frac{Z_1 - 1}{2}V]$ (particle 2') is the nucleus which has lost the proton).

The transition probability per unit time and the cross section $\sigma_{bf}(A_1, A_2)$ of CICP-PE with bound-free (bf) electron transitions can be determined with the aid of standard second order perturbation calculation of quantum mechanics. The cross section has the form $\sigma_{bf}(A_1, A_2) = \frac{\pi}{a} \sigma_{bf}(A_1, A_2)$, where $v$ is the relative velocity of the two atoms, $c$ is the velocity of light (in vacuum). (The cross section of CICP-PE with bound-bound electron transition is neglected since it has proved to be much smaller than $\sigma_{bf}$.) The calculation of $\sigma_{bf}$ is similar to the calculation of CICP by neutron exchange [1]. The differences are the appearance of two Coulomb factors $F_{2/3}$ and $F_{4/4}$ which multiply the cross section and $\Delta_n, \frac{\Delta_z}{\Delta_1}$ are changed to $\Delta_p, \left(1 - \frac{Z}{Z_1}\right)$, respectively, in Eqs.(9)-(12) of [1]. $\Delta_p = 7.288969$ MeV is the energy excess of the proton. ($F_{2/3}$ and $F_{4/4}$ are determined in the Appendix.) Here we repeat some essential features of the calculation. It is carried out in one particle nuclear model. The motions of the centers of mass of the two atoms are taken into account. Hydrogen like state of binding energy $E_{Bi}$ and Coulomb-factor corrected plane wave are used as initial, bound and final, free electron states. The dipole term of the Coulomb interaction reads as

$$V_{C}^{dip} = \left(1 - \frac{Z}{Z_1}\right)^2 \frac{e^2}{\pi} \frac{1}{x} \sum_{n=-1}^{\infty} \frac{1}{Y_{1m}(\Omega_m)} Y_{1m}(\Omega_1),$$

where $Z_1$ and $A_1$ are charge and mass numbers of the first nucleus, $e$ is the elementary charge, $x_1, x_2$ and $\Omega_1, \Omega_2$ are magnitudes and solid angles of vectors $x_1, x_2$, which are the relative coordinates of the proton and the electron in the first atom, respectively and $Y_{1m}$ denotes spherical harmonics. The order of magnitude of the cross section produced by the $L$-th pole coupling is $(R/r)^{2L-2}$ times smaller than the cross section produced by the dipole coupling where $R$ and $r$ are the nuclear and atomic radii. Therefore the leading term to the cross section is produced by the dipole coupling. The motion of the intermediate proton and the two final nuclei are also described by plane waves. The rest masses of the two initial nuclei of mass numbers $A_1$ and $A_2$ are $m_1 = A_1 m_0$ (particle 2) and $m_2 = A_2 m_0$ (particle 4) where $m_0 = 931.494$ MeV is the atomic energy unit. For the nuclear potential a rectangular potential well is assumed, i.e. $V_{st} = -V_0$ ($x_2 \leq R_{A_2}$) and $V_{st} = 0$ ($x_2 > R_{A_2}$) where $x_2$ is the magnitude of vector $x$, which is the relative coordinate of the neutron in the second nucleus and $R_{A_2}$ is its radius. Direct proton capture may be assumed at the surface of the second nucleus (of $A_2$). The effective volume in which strong interaction induces proton capture can be considered as a shell of a sphere of radius $R_{A_2}$ and of thickness $L$, where $L$ is the mean free path of the ingoing proton in the nucleus [2].

Introducing the wave vectors $k$, $k_1$, $k_2$ of the free electron and particles $A_1^{-1}W$ (particle 2') and $A_2^{-1}W$ (particle 5), respectively, the analysis of $\sigma_{bf}$ shows that, similarly to the CICP by neutron exchange [1], those processes give essential contribution to the cross section in which $k_e \ll k_1$ and $k_e \ll k_2$ where $k_e, k_1$ and $k_2$ are the magnitudes of the wave vectors of $k_e, k_1$ and $k_2$. (In this case as a consequence of momentum conservation $k_1 = -k_2$, furthermore the intermediate proton has wave vector $-k_2$.)

The initial and final nuclear states have the form: $\phi_i(x_1) = \varphi_i(x_1) Y_{1m_1}(\Omega_1)/\sqrt{x_1}$ and $\phi_f(x_2) = \varphi_f(x_2) Y_{1m_2}(\Omega_2)/\sqrt{x_2}$ with $\varphi_i(x_1) / x_1$ and $\varphi_f(x_2) / x_2$ denoting the radial parts of the one particle shell-model solutions of quantum numbers $l_i, m_i$ and $l_f, m_f$. For $\varphi_i(x_1)$ and $\varphi_f(x_2)$ the corresponding part $R_{0\lambda} = b_k^{-1/2} \Gamma(\Lambda + 3/2)^{-1/2} 2k_{\lambda+1} \exp(-\rho_k^2/2)$ of the 0Λ one particle spherical shell model states $\lambda$ is applied. Here

$$\rho_k = x_k / b_k, b_k = \left(\frac{\hbar c}{m a_{sh,k}}\right)^{1/2} \text{and } h_{sh,k} = 41 A_{\nu}^{1/3}/(\text{MeV units}, \text{[3]})$$

with $k = 1, 2$ corresponding to $A_1$ and $A_2$, and $\Gamma(x)$ is the gamma function. The case of spherical shell model states of $0\lambda_i$ initial nuclear state and of $0\lambda_f$ final nuclear state is investigated.

The initial electronic state is a 1s state of the form $R_i (x_e) = 2 a^{-3/2} \exp(-x_e/a)$ with $a = a_0 / Z_{eff}$, where $a_0$ is the Bohr-radius, $Z_{eff} = \sqrt{E_B / \text{Ryd}}$ and $R_y$ is the Rydberg energy. In the Coulomb-corrected plane wave applied for the final free electron the $F_{cb}(k_e) = 2\pi / (k_e a_0)$ approximation is used, where $F_{cb}(k_e)$ is the Coulomb factor of the electron. Keeping the leading term of $J_L^2$ in [1] and in the case of $l_i = even [l_i = 2; \text{Al}(5^2/2, 0d)]$ to be investigated one obtains

$$\sigma_{bf,sh} = \frac{2^{10} a_-^3}{3} \left(1 - \frac{Z_1}{A_1}\right)^2 \frac{V_0^2}{(\hbar c)^2} \frac{b_k^4 L^2}{a_{sh,k}^2} \frac{m_0}{m_e} a_{12}$$

$$\times (2l_f + 1) \frac{2^{2l_f + 3} e^{-\rho_k^2}}{\Gamma(l_f + 1/2)} \sum_{\lambda = 0}^{\Lambda, \lambda = 1} N_{1\lambda} (k_0 b_k)^{2\lambda} S_{\lambda}.$$ 

where $a_{sh,k} = h/(m_e c)$, $m_e$ is the rest mass of the electron, $a_{12} = (A_1 - 1)(A_2 + 1)/(A_1 + A_2)$, $\rho_f = R_{A_2}/b_2$, $k_0 = \sqrt{2m_0 \Delta_{Bi} A_{12} / \Lambda}$, and

$$N_{1\lambda} = (2\lambda + 1) \left(\frac{l_i}{0} \frac{1}{0} \frac{\lambda}{0} \right)^2.$$ 

The parenthesized expression is Wigner 3j symbol. (The suffix $sh$ denotes that the quantity is calculated in the one particle spherical shell model.)

$$S_{\lambda} = \int_0^1 f(x) g_\lambda(x) h_1(x) h_2(x) dx,$$

$$f(x) = \frac{(1 - x^2)^{2}\lambda + 1 + e^{-(-k_0 b_k)^2 x^2} \int_{l_1 + \frac{1}{2}}^{l_1 + \frac{1}{2}} \left(4 \int_{l_1 + \frac{1}{2}}^{l_1 + \frac{1}{2}} \frac{A_{12}^2 x^2}{A_1^2} x^2 + 1 + \xi\right)^{\lambda - 1} dx \right)^2},$$

$$x = k_2 / k_0, \xi = (\Delta_p - \Delta_{-} - E_{Bi}) / \Delta_{Bi}$$

and $\Delta_{Bi} = \Delta - E_{Bi}$. $J_{l_1 + \frac{1}{2}}$ is a Bessel-function of the first kind. In
Eq. (3) $\lambda(x) = 1$ if $\lambda = l + 1$ and
\[
g_\lambda(x) = (2l + 1)^2 - 2(l + 1)(k_0b_1x)^2 + (k_0b_1x)^4
\] (7)
if $\lambda = l - 1$. $h_j(x) = d_j(x)/[\exp(d_j(x)) - 1]$, $j = 1, 2$
with
\[
d_1(x) = 2\pi(Z_1 - 1)\alpha_f \frac{1}{x} \sqrt{\frac{(A_1 + A_2) m_0 e^2}{2 A_1 (A_2 + 1) \Delta B_2}}
\] (8)
and
\[
d_2(x) = 2\pi Z_2\alpha_f \frac{1}{x} \sqrt{\frac{(A_1 + A_2) m_0 e^2}{2 (A_1 - 1) (A_2 + 1) \Delta B_1}}.
\] (9)
$\alpha_f$ denotes the fine structure constant. In the numerical calculation $V_0 = 50 \text{ MeV}$ is used.

The differential cross section $d\sigma_{\text{obs,sh}}/dE_2$ of the process can be determined with the aid of
\[
P(x) = \sum_{\lambda = l_i \pm 1} N_{\lambda}(k_0b_1)^{2\lambda} \lambda \frac{f(x) \lambda(x) h_1(x) h_2(x)}{\Gamma(\lambda + \frac{1}{2})} x
\] (10)
as $d\sigma_{\text{obs,sh}}/dE_2 = K_{\text{bf}} [P(x)]_{x = \sqrt{\frac{E_2}{E_{\text{bf}}}}} / (2\Delta B_2)$ where $z = E_2/E_{\text{bf}}$ with $E_{\text{bf}} = (A_1 - 1) \Delta B_2 / (A_1 + A_2)$, which is the possible maximum of the kinetic energy of particle $A_{\text{bf}} + 1$ (particle 5) created in the process, $K_{\text{bf}}$ stands for the whole factor which multiplies the sum in (10). $d\sigma_{\text{obs,sh}}/dE_2$ has accountable values near below $z = 1$, i.e. if $E_2 < E_{\text{bf}}$.

The differential cross section $d\sigma_{\text{obs,sh}}/dE_e = K_{\text{bf}} [P(x)]_{x = \sqrt{\frac{E_e}{\Delta B_1}}} / (2\Delta B_1)$ can also be determined with the aid of $P(x)$ where $z = E_e/\Delta B_1$, $E_e$ is the kinetic energy of the electron and $K_{\text{bf}}$ is defined above. $d\sigma_{\text{obs,sh}}/dE_e$ has accountable values near above $z = 0$, i.e. if $E_e > 0$.

It is a special case of (8) if the two initial nuclei are identical. In this case the CICP-PF reads as
\[
e_1 + \frac{A_1}{Z_1}X + \frac{A_2}{Z_2}Y \rightarrow e' + \frac{A_1 - 1}{Z_1 - 1}V + \frac{A_1 + 1}{Z_1 + 1}W + \Delta.
\] (11)

For example of such a case the reaction $e + ^{27}Al + ^{27}Al \rightarrow e' + ^{56}Fe + ^{28}Si + \Delta$ is considered when the reaction starts from the K shell. The initial and final nuclear states are supposed to be 0d spherical shell model states of $l_i = l_f = 2$, $\Delta = 3.31362 \text{ MeV}$. The electron binding energy in the K shell is $E_{\text{bi}} = 1.5596 \text{ keV}$ and $\Delta_e = -0.98235 \text{ MeV}$. In this case $E_{\text{bf}} = 3.1894 \text{ MeV} and$
K_{\text{bf}} / (2E_{\text{bf}}) = 2.41 \times 10^{-35} \text{ cm}^2 \text{ MeV}^{-1}$. $\sigma_{\text{obs,sh}}(K) = 2.41 \times 10^{-46} \text{ cm}^2$ is obtained in the case of bound-free CICP from the K shell of Al. If one compares this result with $\sigma_{\text{obs,sh}}(K) = 8.25 \times 10^{-45} \text{ cm}^2$ obtained in case of CICP by neutron exchange in Ne one can recognize that the ratio of the two cross sections is only 0.030. At first sight it seems to be larger than expected since two Coulomb factors appear in the cross section. But as it was said earlier the intermediate proton has wave vector $-k_2$ and thus its energy $E_3 = h^2k_2^2 / (2m_0)$ with
\[
hk_2 = \frac{h}{2}\sqrt{\frac{m_0 \Delta B_2}{2A_1}}.
\]
It gives $E_3 = x^2 \Delta B_2 A_1/2$ since $A_{\text{bf}} = A_2$ and near below $x = 1$ the value of $E_3$ is large enough to result moderately small Coulomb factors.

For a gas of atomic Al and of number density $n$ the transition probability per unit time $\lambda_1 = cn \sum_{A_1} r_{A_1} \sigma_{\text{obs,sh}}(K)$ since the relative natural abundance $r_{A_1}$ of the initial $\frac{1}{2}$ Al isotope equals unity. $\lambda_1$ is estimated as $\lambda_1 > \lambda_1(K)$, which is the transition probability per unit time of the bound-free CICP-PF from the K shell of Al ($\lambda_1(K) = cn \sigma_{\text{obs,sh}}(K)$), resulting $\lambda_1 > 1.92 \times 10^{-16} \text{ s}^{-1}$ and $r_{\text{tot}} > 5.09 \times 10^{-1} \text{ cm}^{-3} \text{ s}^{-1}$ for a gas of normal state ($n = 2.652 \times 10^{13} \text{ cm}^{-3}$, $T = 273.15 \text{ K}$, $p = 100 \text{ kPa}$) and $r_{\text{tot}} = n\lambda_1$, which is the total rate per unit volume of the sample, in this case since $r_{A_1} = 1$.

In Table I, the $\Delta_-$, $\Delta_+$ and $\Delta$ data of some cooperative internal conversion processes by proton exchange (data to reaction (11)) can be found. In the first column the initial stable isotope of relative natural abundance unity and in the second column the reaction products are listed.

There are other possibilities to realize CICP, when a charged heavy particle (such as $d$, $t$, $\frac{3}{2}He$ and $\frac{3}{2}He$) is exchanged instead of proton exchange. The process is called cooperative internal conversion process by heavy charged particle exchange (CICP-HCPE) and it can be visualized with the aid of Fig.1 too. Denoting the intermediate particle (particle 3 in Fig. 1) by $\frac{3}{2}w$, which is exchanged, the cooperative internal conversion process by heavy charged particle exchange reads as
\[
e + \frac{A_1}{Z_1}X + \frac{A_2}{Z_2}Y \rightarrow e' + \frac{A_1 - A_2}{Z_1 - 3}V + \frac{A_1 + A_2}{Z_2 + 3}W + \Delta.
\] (12)
Here $e$ and $e'$ denote bound and free electron and $\Delta$ is the energy of the reaction, i.e. the difference between the rest energies of initial $\frac{A_1}{Z_1}X + \frac{A_2}{Z_2}Y$ and final $\frac{A_1 - A_2}{Z_1 - 3}V + \frac{A_1 + A_2}{Z_2 + 3}W$ states. $\Delta = \Delta_+ + \Delta_-$, with $\Delta_- = \Delta_{Z_1} - \Delta_{Z_1 - 3}$ and $\Delta_+ = \Delta_{Z_2} - \Delta_{Z_2 + 3} + \Delta_{Z_1}$.

A. Appendix - Coulomb factors $F_{23}$ and $F_{34}$

Since particles $2'$, 3 and 4 all have positive charge, furthermore they are all heavy, the two essential Coulomb factors, which appear in the cross section, are $F_{23}$ and $F_{34}$. Since Coulomb factors $F_{23}$ and $F_{34}$ determine the order of magnitude of the cross section of the process (as it is proportional to $F_{23}F_{34}$) we treat them in more detail in the case of CICP-PE in the following.

We adopt the approach standard in nuclear physics when describing the cross section of nuclear reactions of heavy, charged particles $j$ and $k$ of like positive charge of charge numbers $z_j$ and $z_k$ and of relative kinetic energy $E$. The cross section of such a process can be derived applying the Coulomb solution $\varphi(r)$,

$$\varphi(r) = e^{i\mathbf{k} \cdot \mathbf{r}} f(\mathbf{k}, \mathbf{r})/\sqrt{V},$$

which is the wave function of a free particle of charge number $z_j$ in a repulsive Coulomb field of charge number $z_k$, in the description of relative motion of projectile and target. In $V$ denotes the volume of normalization, $\mathbf{r}$ is the relative coordinate of the two particles, $\mathbf{k}$ is the wave number vector in their relative motion and

$$f(\mathbf{k}, \mathbf{r}) = e^{-\pi \eta_{jk}/2} \Gamma(1 + i\eta_{jk}) F_1(-i\eta_{jk}, 1; i|\mathbf{k} \cdot \mathbf{r}|),$$

where $F_1$ is the confluent hypergeometric function and $\Gamma$ is the Gamma function. Since $\varphi(r) \sim e^{-\pi \eta_{jk}/2} \Gamma(1 + i\eta_{jk})$, the cross section of the process is proportional to

$$\left| e^{-\pi \eta_{jk}/2} \Gamma(1 + i\eta_{jk}) \right|^2 \frac{2\pi \eta_{jk}(E)}{\exp[2\pi \eta_{jk}(E)] - 1} = F_{jk}(E),$$

which is the so-called Coulomb factor. Here

$$\eta_{jk}(E) = z_j z_k \alpha_f \sqrt{ \frac{m_0 c^2}{2E} }$$

is the Sommerfeld parameter in the case of colliding particles of mass numbers $A_j$, $A_k$ and rest masses $m_j = A_j m_0$, $m_k = A_k m_0$. $m_0 c^2 = 931.494 \text{ MeV}$ is the atomic energy unit, $\alpha_f$ is the fine structure constant and $E$ is taken in the center of mass (CM) coordinate system.

$$a_{jk} = \frac{A_j A_k}{A_j + A_k}$$
is the reduced mass number of particles $j$ and $k$ of mass numbers $A_j$ and $A_k$.

If initial particles have negligible initial momentum then in the final state $k_1 = -k_2$ ($k_{\text{particle},2'} = -k_{\text{particle},5}$) because of momentum conservation. (It was obtained [1] that the process has accountable cross section if the momentum of the final electron can be neglected.) In this case the momentum and energy of the virtual particle 3 (e.g. proton) are $k_{\text{particle},3} = -k_{\text{particle},2'} = k_{\text{particle},5} \equiv k_2$ and $E_3 = \hbar^2 k_2^2 / (2m_3)$, where $\hbar$ is the reduced Planck constant. Calculating the Coulomb factor $F_{2'3}$ [see (17)] between particles 2' and 3 the energy $E_3$ is given in their CM coordinate system (since $k_{\text{particle},3} = -k_{\text{particle},2'}$) thus $E_3$ can be substituted directly in (18) producing

$$\eta_{2'3} = \frac{(Z_1 - 1) \alpha \, 1}{x} \sqrt{\frac{A_1 + A_2}{A_1 (A_2 + 1)}} \frac{m_0 c^2}{2 \Delta B_i}.$$  

(20)

in case of proton exchange. Here the $k_2 = k_0 x$ substitution is also used. Calculating the Coulomb factor $F_{34}$, the energy $E_3$ of particle 3 is now given in the laboratory frame of reference since particle 4 is at rest. In the CM system of particles 3 and 4 the energy $E_3(\text{CM})$ is

$$E_3(\text{CM}) = \frac{A_{\text{particle},4}}{(A_{\text{particle},3} + A_{\text{particle},4})} E_3.$$  

(21)

Substituting it into (18)

$$\eta_{34} = Z_2 \alpha f \, 1 \sqrt{\frac{(A_1 + A_2) m_0 c^2}{2 (A_1 - 1) (A_2 + 1) \Delta B_i}}$$  

(22)

in case of proton exchange.
