(Dated: June 28, 2022)

We implement a comprehensive and detailed study of the alignment of Yukawa couplings in the so-called Higgs basis taking the framework of general two Higgs doublet models (2HDMs). We clarify the model input parameters and derive the Yukawa couplings considering the two types of CP-violating sources: one from the Higgs potential and the other from the three complex alignment parameters $\zeta_f = u, d, e$. We consider the theoretical constraints from the perturbative unitarity and for the Higgs potential to be bounded from below as well as the experimental ones from electroweak precision observables. Also considered are the constraints on the alignment parameters from flavor-changing $\tau$ decays, $Z \to b\bar{b}$, $\epsilon_K$, and the radiative $b \to s\gamma$ decay. By introducing the basis-independent Yukawa delay factor $\Delta_{H_1 f f} \equiv |\zeta_f|(|1 - g_{H_1 V V}^2|^{1/2}$, we scrutinize the alignment of the Yukawa couplings of the lightest Higgs boson to the SM fermions.

I. INTRODUCTION

Since the discovery of the 125 GeV Higgs boson in 2012 at the LHC [1,2], it has been inspected very closely and extensively. At the early stage, several model-independent studies [3,25] show that there were some rooms for it to be unlike the one predicted in the Standard Model (SM) but, after combining all the LHC Higgs data at 7 and 8 TeV [26] and especially those at 13 TeV [27,45], it turns out that it is best described by the SM Higgs boson. Specifically, the third-generation Yukawa couplings have been established. And the most recent model-independent study [46] shows that the 1σ error of the top-quark Yukawa coupling is about 6% while those of the bottom-quark and tau-lepton ones are about 10%. In addition, the possibility of negative top-quark Yukawa coupling has been completely ruled out and the bottom-quark Yukawa coupling shows a preference of the positive sign at about 1.5σ level. For the tau-Yukawa coupling, the current data still do not show any preference for its sign yet. On the other hand, the coupling to a pair of massive vector bosons is constrained to be consistent with the SM value within about 5% at 1σ level.

Even though we have not seen any direct hint or evidence of new physics beyond the SM (BSM), we are eagerly anticipating it with various compelling motivations such as the tiny but non-vanishing neutrino masses, matter dominance of our Universe and its evolution driven by dark energy and dark matters, etc [49]. In many BSM models, the Higgs sector is extended and it results in existence of several neutral and charged Higgs bosons. Their distinctive features depending on new theoretical frameworks could be directly probed through their productions and decays at future high-energy and high-precision experiments [50,55].

By the alignment of the Yukawa couplings in general 2HDMs [66,75], first of all, we imply that the Yukawa matrices describing the couplings of the two Higgs doublets to the SM fermions should be aligned in the flavor space to avoid the tree-level Higgs-mediated flavor-changing neutral current (FCNC). In 2HDMs, there are three neutral Higgs bosons and one of them should be identified as the observed one at the LHC which weighs 125.5 GeV [76]. In this case, by the alignment of the Yukawa couplings, we also mean that the couplings of this SM-like Higgs boson to the SM fermions should be the same as those of the SM Higgs boson itself or its couplings are strongly constrained to be very SM-like by the current LHC data as outlined above. One of the popular ways to achieve this alignment is to identify the lightest neutral Higgs boson as the 125.5 GeV one and assume that all the other Higgs bosons are heavier or much heavier than the lightest one [77,78]. But this decoupling scenario is not phenomenologically interesting and another scenario is suggested in which all the couplings of the SM-like Higgs candidate are (almost) aligned with those of the SM Higgs while the other Higgs bosons are not so heavy [79,82].

The alignment of Yukawa couplings are previously discussed and studied [80,83]. For some recent works, see, for example, Refs. [84,87]. In this work, taking the framework of general 2HDMs, we implement a comprehensive and detailed study of the alignment of Yukawa couplings in the so-called Higgs basis [73,74,88,92] in which only the doublet containing the SM-like Higgs boson develops the non-vanishing vacuum expectation value (vev) v. For the alignment of the Yukawa matrices, we assume that the Yukawa matrices are aligned in the flavor space [93,95] by introducing the three alignment parameters ζ_f with f = u, d, e for the couplings to the up-type quarks, the down-type quarks, and the charged leptons, respectively. Under this assumption, there are no Higgs-mediated FCNC couplings at tree level and, at higher orders, they are very suppressed [94,95]. And then, we identify the lightest neutral Higgs boson as the 125.5 GeV one and consider the alignment of its Yukawa couplings as the masses of the heavier Higgs bosons increase or as the heavy Higgs bosons decouple. We configure that the decoupling of the Yukawa couplings of the lightest Higgs boson is delayed by the amount of Δ_H_{ff} ≡ |ζ_f| (1 − g_{H,VV}^2)^{1/2} compared to its coupling to a pair of massive vector bosons, g_{H,VV}. We observe that the Yukawa delay factor Δ_H_{ff} can be sizable even when g_{H,VV} ∼ 1 if |ζ_f| is significantly larger than 1. We consider the upper limit on |ζ_u| from Z → b̄b and eγ, and, for |ζ_d| and |ζ_e|, we demonstrate that they are constrained to be small by the precision LHC Higgs data unless the so-called wrong-sign alignment of the Yukawa couplings [78,99,102] occurs. Note that the Yukawa delay factor is basis-independent and can be used even when some of the Higgs potential parameters and/or all of the three alignment parameters are complex.

We emphasize that we are reconsidering the decoupling behavior of the Yukawa couplings in the light of the new basis-independent measure of the Yukawa delay factor Δ_H_{ff} taking the aligned 2HDM in the Higgs basis. In the Higgs basis, contrasting to the relatively well-known Φ basis, it is easier to understand the analytic structure of intercorrelations among the model parameters. On the other hand, in the aligned 2HDM, there are three uncorrelated

1 Throughout this work, we are using the results presented in Ref. [25] which are based on global fits of the Higgs boson couplings to all the LHC Higgs data at 7 TeV, 8 TeV, and 13 TeV available up to the Summer 2018, corresponding to integrated luminosities per experiment of approximately 5/fb at 7 TeV, 20/fb at 8 TeV and up to 80/fb at 13 TeV. We note that there are more datasets at 13 TeV up to 139/fb and 137/fb collected with the ATLAS and CMS experiments, respectively, see Refs. [47,48]. Though, without a combined ATLAS and CMS analysis, it is difficult to say conclusively how much the full 13-TeV dataset improves the measurements of Higgs boson properties quantitatively, we observe that the 1σ errors are reduced by the amount of about 30% by comparing the results presented in Ref. [47] with those in Ref. [25] in which the dataset up to 80/fb is used.

2 Precisely speaking, here the sign of the bottom-quark Yukawa coupling is relative to the top-quark Yukawa coupling configured through the b- and t-quark loop contributions to the Hgg vertex.

3 In the wrong-sign alignment limit, the Yukawa couplings are equal in strength but opposite in sign to the SM ones.
complex alignment parameters which provide further CP-violating sources in addition to those in the Higgs potential. The aligned 2HDM accommodates the conventional four types of 2HDMs as the limiting cases when the alignment parameters are real and fully correlated.

This paper is organized as follows. Section II is devoted to a brief review of the 2HDM Higgs potential, the mixing among neutral Higgs bosons and their couplings to the SM particles in the Higgs basis. In Section III, we elaborate on the constraints from the perturbative unitarity, the Higgs potential bounded from below, and the electroweak precision observables as well as the flavor constraints on the alignment parameters. And we carry out numerical analysis of the constraints and the alignment of Yukawa couplings in Section IV. A brief summary and conclusions are made in Section V.

II. TWO HIGGS DOUBLET MODEL IN THE HIGGS BASIS

In this section, we study the two Higgs doublet model taking the so-called Higgs basis [73, 74, 88–92]. We consider the general potential containing two complex SU(2)l doublets Φ1 and Φ2 with the same hypercharge Y = 1/2 may be given by

\[ V_\Phi = \mu_1^2(\Phi_1^\dagger \Phi_1) + \mu_2^2(\Phi_2^\dagger \Phi_2) + m_{12}^2(\Phi_1^\dagger \Phi_2) + m_{12}^2(\Phi_2^\dagger \Phi_1) + \lambda_1(\Phi_1^\dagger \Phi_1)^2 + \lambda_2(\Phi_2^\dagger \Phi_2)^2 + \lambda_3(\Phi_1^\dagger \Phi_1)(\Phi_2^\dagger \Phi_2) + \lambda_4(\Phi_1^\dagger \Phi_2)(\Phi_2^\dagger \Phi_1) + \lambda_5(\Phi_2^\dagger \Phi_2)^2 + \lambda_6(\Phi_1^\dagger \Phi_1)(\Phi_1^\dagger \Phi_1) + \lambda_7(\Phi_1^\dagger \Phi_2)(\Phi_2^\dagger \Phi_1) + \lambda_8(\Phi_2^\dagger \Phi_2)(\Phi_1^\dagger \Phi_1), \]

in terms of 2 real and 1 complex dimensionful quadratic and 4 real and 3 complex dimensionless quartic couplings. Note that the Z2 symmetry under Φ1 → ±Φ1 and Φ2 → ±Φ2 is hardly broken by the non-vanishing quartic couplings λ6 and λ7 and, in this case, we have three rephasing-invariant CP-violating phases in the potential. With the general parameterization of two scalar doublets Φ1,2 as

\[ \Phi_1 = \left( \frac{1}{\sqrt{2}} (v_1 + \phi_1 + ia_1) \right); \quad \Phi_2 = e^{i\xi} \left( \frac{1}{\sqrt{2}} (v_2 + \phi_2 + ia_2) \right), \]

and denoting \( v_1 = v \cos \beta = vc_\beta \) and \( v_2 = v \sin \beta = vs_\beta \) with \( v = \sqrt{v_1^2 + v_2^2} \), one may remove \( \mu_1^2, \mu_2^2, \) and \( 3m(m_{12}^2 e^{i\xi}) \) from the 2HDM potential using three tadpole conditions:

\[ \mu_1^2 = -v^2 \left[ \lambda_1 c_\beta^2 + \frac{1}{2} \lambda_3 s_\beta^2 + c_\beta s_\beta \text{Re}(\lambda_6 e^{i\xi}) \right] + s_\beta^2 M_{H^\pm}^2, \]
\[ \mu_2^2 = -v^2 \left[ \lambda_2 s_\beta^2 + \frac{1}{2} \lambda_3 c_\beta^2 + c_\beta s_\beta \text{Re}(\lambda_7 e^{i\xi}) \right] + c_\beta^2 M_{H^\pm}^2, \]
\[ 3m(m_{12}^2 e^{i\xi}) = -\frac{v^2}{2} \left[ 2 c_\beta s_\beta \text{Im}(\lambda_5 e^{2i\xi}) + c_\beta^2 \text{Im}(\lambda_6 e^{i\xi}) + s_\beta^2 \text{Im}(\lambda_7 e^{i\xi}) \right], \]

with the square of the charged Higgs-boson mass

\[ M_{H^\pm}^2 = -\frac{\text{Re}(m_{12}^2 e^{i\xi})}{c_\beta s_\beta} - \frac{v^2}{2c_\beta s_\beta} \left[ \lambda_4 c_\beta s_\beta + 2 c_\beta s_\beta \text{Re}(\lambda_5 e^{2i\xi}) + c_\beta^2 \text{Re}(\lambda_6 e^{i\xi}) + s_\beta^2 \text{Re}(\lambda_7 e^{i\xi}) \right]. \]

In contrast with the Higgs basis which has been taken for this work, we address it as the Φ basis.
On the other hand, in the Higgs basis where only one doublet contains the non-vanishing vev \( v \), the general 2HDM scalar potential again contains three (two real and one complex) massive parameters and four real and three complex dimensionless quartic couplings and it might take the same form as in the \( \Phi \) basis:

\[
V_{\Phi} = V_1(\Phi_1^2) + V_2(\Phi_1^2\Phi_2^2) + V_3(\Phi_1^2\Phi_2^2) + V_4(\Phi_1^2\Phi_2^2) + V_5(\Phi_1^2\Phi_2^2) + V_6(\Phi_1^2\Phi_2^2) + V_7(\Phi_1^2\Phi_2^2),
\]

where the new complex SU(2)_L doublets of \( H_1 \) and \( H_2 \) are given by the linear combinations of \( \Phi_1 \) and \( \Phi_2 \) as follows

\[
\begin{align*}
H_1 &= c_\beta \Phi_1 + e^{-i\xi} s_\beta \Phi_2 = \left( \frac{G^+}{\sqrt{2}} (v + \phi_1 + iG^0) \right), \\
H_2 &= -s_\beta \Phi_1 + e^{-i\xi} c_\beta \Phi_2 = \left( \frac{H^+}{\sqrt{2}} (\phi_2 + ia) \right),
\end{align*}
\]

with the relations

\[
\phi_1 \equiv c_\beta \phi_1 + s_\beta \phi_2, \quad \phi_2 \equiv -s_\beta \phi_1 + c_\beta \phi_2; \quad a = -s_\beta a_1 + c_\beta a_2,
\]

in terms of \( \phi_{1,2} \) and \( a_{1,2} \) in Eq. \([2]\). Incidentally, we have that \( G^0 = c_\beta a_1 + s_\beta a_2, \ G^+ = c_\beta \phi_1^+ + s_\beta \phi_2^+ \), and \( H^+ = -s_\beta \phi_1^+ + c_\beta \phi_2^+ \). Note that only the neutral component of the \( H_1 \) doublet develops the non-vanishing vacuum expectation value \( v \) and it contains only one physical degree of freedom let alone the Goldstone modes. In the so-called decoupling limit, \( H_1 \) take over the role of the SM SU(2)_L doublet and the remaining three Higgs states are accommodated only by the \( H_2 \) doublet.\(^\dagger\)

The potential parameters \( Y_{1,2,3} \) and \( Z_{1-7} \) in the Higgs basis could be related to those in the \( \Phi \) basis through:

\[
\begin{align*}
Y_1 &= \mu_1^2 c_\beta^2 + \mu_2^2 s_\beta^2 + \text{Re}(m_{12}^2 e^{i\xi}) s_\beta^2, \\
Y_2 &= \mu_1^2 s_\beta^2 + \mu_2^2 c_\beta^2 - \text{Re}(m_{12}^2 e^{i\xi}) s_\beta^2, \\
Y_3 &= -(\mu_1^2 - \mu_2^2) c_\beta s_\beta + \text{Re}(m_{12}^2 e^{i\xi}) c_\beta s_\beta + i \text{Im}(m_{12}^2 e^{i\xi}),
\end{align*}
\]

for two real and one complex dimensionful parameters and \(^\dagger\)

\[
\begin{align*}
Z_1 &= \lambda_1 c_\beta^4 + \lambda_2 s_\beta^4 + 2\lambda_{345} c_\beta^2 s_\beta^2 + [\text{Re}(\lambda_6 e^{i\xi}) c_\beta^2 - \text{Re}(\lambda_7 e^{i\xi}) s_\beta^2] s_\beta^2, \\
Z_2 &= \lambda_1 s_\beta^4 + \lambda_2 c_\beta^4 + 2\lambda_{345} c_\beta^2 s_\beta^2 - [\text{Re}(\lambda_6 e^{i\xi}) s_\beta^2 + \text{Re}(\lambda_7 e^{i\xi}) c_\beta^2] s_\beta^2, \\
Z_3 &= \lambda_3 + 2(\lambda_1 - \lambda_2 - 2\lambda_{345}) c_\beta^2 s_\beta^2 - [\text{Re}(\lambda_6 e^{i\xi}) - \text{Re}(\lambda_7 e^{i\xi})] c_\beta s_\beta s_\beta, \\
Z_4 &= \lambda_4 + 2(\lambda_1 + \lambda_2 - 2\lambda_{345}) c_\beta^2 s_\beta^2 - [\text{Re}(\lambda_6 e^{i\xi}) - \text{Re}(\lambda_7 e^{i\xi})] c_\beta s_\beta s_\beta, \\
Z_5 &= (\lambda_1 + \lambda_2 - 2\lambda_{345}) c_\beta^4 s_\beta^4 + [\text{Re}(\lambda_6 e^{i\xi}) - \text{Re}(\lambda_7 e^{i\xi})] c_\beta s_\beta s_\beta + i [\text{Im}(\lambda_5 e^{2i\xi}) c_\beta s_\beta + \text{Im}(\lambda_6 e^{i\xi}) c_\beta s_\beta + \text{Im}(\lambda_7 e^{i\xi}) c_\beta s_\beta], \\
Z_6 &= (-\lambda_1 c_\beta^2 + \lambda_2 s_\beta^2) s_\beta s_\beta + 2\lambda_{345} c_\beta s_\beta s_\beta + [\text{Re}(\lambda_6 e^{i\xi}) (c_\beta^2 - 3s_\beta^2) c_\beta^2 + \text{Re}(\lambda_7 e^{i\xi}) (3c_\beta^2 - s_\beta^2) s_\beta^2] + i [\text{Im}(\lambda_5 e^{2i\xi}) s_\beta s_\beta + \text{Im}(\lambda_6 e^{i\xi}) c_\beta s_\beta + \text{Im}(\lambda_7 e^{i\xi}) s_\beta^2], \\
Z_7 &= (-\lambda_1 s_\beta^2 + \lambda_2 c_\beta^2) s_\beta s_\beta - 2\lambda_{345} c_\beta s_\beta s_\beta + [\text{Re}(\lambda_6 e^{i\xi}) (3c_\beta^2 - s_\beta^2) s_\beta^2 + \text{Re}(\lambda_7 e^{i\xi}) (c_\beta^2 - 3s_\beta^2) c_\beta^2] + i [-\text{Im}(\lambda_5 e^{2i\xi}) s_\beta s_\beta + \text{Im}(\lambda_6 e^{i\xi}) s_\beta^2 + \text{Im}(\lambda_7 e^{i\xi}) c_\beta s_\beta].
\end{align*}
\]

\(^5\) For a numerical study later, the notations of \( \phi_1 = h, \ \phi_2 = H, \) and \( a = A \) are taken in the decoupling limit.

\(^6\) We find that our results are consistent with those presented in, for example, Ref. \([\dagger]\).
\((\lambda_6, 7\epsilon i^\xi) \leftrightarrow -(\lambda_6, 7\epsilon i^\xi)^*\). The tadpole conditions in the Higgs basis, which are much simpler than those in the \(\Phi\) basis as shown in Eq. (3), are

\[ Y_1 + Z_1 v^2 = 0; \quad Y_3 + \frac{1}{2} Z_6 v^2 = 0, \tag{10} \]

where the first condition comes from \(\langle \frac{\partial V_H}{\partial \phi_1^*} \rangle = 0\) and the second one from \(\langle \frac{\partial V_H}{\partial \phi_2} \rangle = 0\) and \(\langle \frac{\partial V_H}{\partial \phi_3} \rangle = 0\). Note that the second condition relates the two complex parameters of \(Y_3\) and \(Z_6\).

### B. Masses, Mixing, and Potential Parameters in the Higgs Basis

In the Higgs basis, the 2HDM Higgs potential includes the mass terms which can be cast into the form consisting of two parts

\[ V_{H,\text{mass}} = M_H^2 H^+ H^- + \frac{1}{2} (\phi_1, \phi_2, a) M_0^2 \begin{pmatrix} \phi_1 \\ \phi_2 \\ a \end{pmatrix}, \tag{11} \]

in terms of the charged Higgs bosons \(H^\pm\), two neutral scalars \(\phi_{1,2}\), and one neutral pseudoscalar \(a\). The charged Higgs boson mass is given by

\[ M_{H^\pm}^2 = Y_2 + \frac{1}{2} Z_3 v^2, \tag{12} \]

while the \(3 \times 3\) mass-squared matrix of the neutral Higgs bosons \(M_0^2\) takes the form

\[ M_0^2 = M_A^2 \text{ diag}(0,1,1) + M_Z^2, \tag{13} \]

where \(M_A^2 = M_{H^\pm}^2 + \left[ \frac{1}{2} Z_4 - \Re(Z_5) \right] v^2\) and the \(3 \times 3\) real and symmetric mass-squared matrix \(M_Z^2\) is given by

\[ \frac{M_Z^2}{v^2} = \begin{pmatrix} 2Z_1 & \Re(Z_6) & -\Im(Z_6) \\ \Re(Z_6) & 2\Re(Z_5) & -\Im(Z_5) \\ -\Im(Z_6) & -\Im(Z_5) & 0 \end{pmatrix}. \tag{14} \]

Note that the quartic couplings \(Z_2\) and \(Z_7\) have nothing to do with the masses of Higgs bosons and the mixing of the neutral ones. They can be probed only through the cubic and quartic Higgs self-couplings, see Eq. (11) while noting that only the \(H_1\) doublet contains the vev \(v \approx 246\) GeV. We further note that \(\varphi_1\) decouples from the mixing with the other two neutral states of \(\varphi_2\) and \(a\) in the \(Z_6\) limit, and its mass squared is simply given by \(2Z_1 v^2\) which gives \(Z_1 \simeq 0.13 (M_H/125.5\text{GeV})^2\). And, in this decoupling limit of \(Z_6 \to 0\), the CP-violating mixing between the two states of \(\varphi_2\) and \(a\) is dictated only by \(3\text{m}(Z_5)\).

Once the \(3 \times 3\) real and symmetric mass-squared matrix \(M_0^2\) is given, the orthogonal \(3 \times 3\) mixing matrix \(O\) is defined through

\[ (\varphi_1, \varphi_2, a)^T_O = O_{\alpha i}(H_1, H_2, H_3)^T, \tag{15} \]

such that \(O^T M_0^2 O = \text{diag}(M_{H_1}^2, M_{H_2}^2, M_{H_3}^2)\) with the increasing ordering of \(M_{H_1} \leq M_{H_2} \leq M_{H_3}\), if necessary. Note that the mass-squared matrix \(M_0^2\) involves only the four (two real and two complex) quartic couplings \{\(Z_1, Z_4, Z_5, Z_6\)\} once \(v\) and \(M_{H^\pm}\) are given. And then, using the matrix relation \(O^T M_0^2 O = \text{diag}(M_{H_1}^2, M_{H_2}^2, M_{H_3}^2)\), one may find the following expressions for the quartic couplings of \{\(Z_1, Z_4, Z_5, Z_6\)\} in terms of the three masses of neutral Higgs bosons

\[ \text{Note that we reserve the notations of } H_i=1,2,3 \text{ for the mass eigenstates of three neutral Higgs bosons taking account of CP-violating mixing in the neutral Higgs-boson sector when } 3\text{m}(Z_{5,6}) \neq 0. \text{ In general, the neutral Higgs bosons do not carry definite CP parities and they become mixtures of CP-even and CP-odd states.} \]
and the components of the $3 \times 3$ orthogonal mixing matrix $O$: 

\[
Z_1 = \frac{1}{2v^2} \left( M_{H_1}^2 O_{\varphi_1}^2 + M_{H_2}^2 O_{\varphi_2}^2 + M_{H_3}^2 O_{\varphi_3}^2 \right),
\]

\[
Z_4 = \frac{1}{v^2} \left[ M_{H_1}^2 (O_{\varphi_2}^2 + O_{\varphi_3}^2) + M_{H_2}^2 (O_{\varphi_3}^2 + O_{\varphi_3}^2) + M_{H_3}^2 (O_{\varphi_3}^2 + O_{\varphi_3}^2) - 2M_{H\pm}^2 \right],
\]

\[
Z_5 = \frac{1}{2v^2} \left[ M_{H_1}^2 (O_{\varphi_2}^2 - O_{\varphi_3}^2) + M_{H_2}^2 (O_{\varphi_2}^2 - O_{\varphi_3}^2) + M_{H_3}^2 (O_{\varphi_2}^2 - O_{\varphi_3}^2) \right]
- \frac{i}{v^2} \left( M_{H_1}^2 O_{\varphi_2} O_{\varphi_3} + M_{H_2}^2 O_{\varphi_2} O_{\varphi_3} + M_{H_3}^2 O_{\varphi_2} O_{\varphi_3} \right),
\]

\[
Z_6 = \frac{1}{v^2} \left( M_{H_1}^2 O_{\varphi_1} O_{\varphi_2} + M_{H_2}^2 O_{\varphi_1} O_{\varphi_2} + M_{H_3}^2 O_{\varphi_1} O_{\varphi_3} \right)
- \frac{i}{v^2} \left( M_{H_1}^2 O_{\varphi_1} O_{\varphi_2} + M_{H_2}^2 O_{\varphi_1} O_{\varphi_2} + M_{H_3}^2 O_{\varphi_1} O_{\varphi_3} \right),
\]

for given $v$ and $M_{H\pm}$.

Now we are ready to consider the input parameters for 2HDM in the Higgs basis. First of all, the input parameters for the Higgs potential Eq. (5) are

\[
\{ Y_1, Y_2, Y_3, Z_1, Z_2, Z_3, Z_4, Z_5, Z_6, Z_7 \}.
\]

Using the tadpole conditions in Eq. (10), the dimensionful parameters $Y_1$ and $Y_3$ can be removed from the set in favor of $v$ and observing that the quartic couplings $Z_2$ and $Z_7$ do not contribute to the mass terms, one may consider the following set of input parameters

\[
\{ v, Y_2; M_{H\pm}, Z_1, Z_4, Z_5, Z_6; Z_2, Z_7 \}.
\]

where we trade the quartic coupling $Z_3$ with the charged Higgs mass $M_{H\pm}$ using the relation $Z_3 = 2 \left( M_{H\pm}^2 - Y_2 \right) / v^2$ with $Y_2$ given. Further using $M_{H\pm}$ and $O$ instead of \{ $Z_1, Z_4, Z_5, Z_6$ \}, we end up with the following set of input parameters:

\[
\mathcal{I} = \{ v, Y_2; M_{H\pm}, M_{H_1}, M_{H_2}, M_{H_3}, \{ O_{3\times3} \}; Z_2, Z_7 \},
\]

which contains 12 real degrees of freedom. If desirable, one may remove the unphysical massive parameter $Y_2$ in favor of the dimensionless quartic coupling $Z_3$ by having an alternative set

\[
\mathcal{I}' = \{ v; M_{H\pm}, M_{H_1}, M_{H_2}, M_{H_3}, \{ O_{3\times3} \}; Z_3, Z_2, Z_7 \},
\]

consisting of 12 real parameters as well.

For example, in the CP-conserving (CPC) case with $3mZ_5 = 3mZ_6 = 0$, one may denote the masses of the three neutral Higgs bosons by $M_A$, $M_{H_1}$, and $M_{H_2}$ or $O^T M_0^2 O = \text{diag}(M_{H_1}^2, M_{H_2}^2, M_A^2)$. Note that $M_{H_2}^2 = 2Z_1v^2$ is for the SM Higgs boson in the decoupling limit of $Z_6 \to 0$. The mixing matrix $O$ can be parameterized as

\[
O_{\text{CPC}} = \begin{pmatrix}
    c_\gamma & s_\gamma & 0 \\
    -s_\gamma & c_\gamma & 0 \\
    0 & 0 & 1
\end{pmatrix},
\]

introducing the mixing angle $\gamma$ between the two CP-even states $\varphi_1$ and $\varphi_2$. In this CP-conserving case, the relations Eq. (16) simplify into

\[
Z_1 = \frac{1}{2v^2} \left( c_\gamma^2 M_{H_1}^2 + s_\gamma^2 M_{H_2}^2 \right), \quad Z_4 = \frac{1}{v^2} \left( s_\gamma^2 M_{H_1}^2 + c_\gamma^2 M_{H_2}^2 + M_A^2 - 2M_{H\pm}^2 \right),
\]

\[
Z_5 = \frac{1}{2v^2} \left( s_\gamma^2 M_{H_1}^2 + c_\gamma^2 M_{H_2}^2 - M_A^2 \right), \quad Z_6 = \frac{1}{v^2} \left( -M_{H_1}^2 + M_{H_2}^2 \right) c_\gamma s_\gamma.
\]

We observe that, in the decoupling limit of $\sin\gamma = 0$, $Z_1 = M_{H_1}^2 / 2v^2$ and $Z_6 = 0$, and $Z_4$ and $Z_5$ are determined by

\footnote{The $3 \times 3$ orthogonal mixing matrix $O$ contains three independent degrees of freedom represented by the three rotation angles.}
the mass differences of \( M^2_{H^+} + M^2_A - 2M^2_{H^0} \) and \( M^2_{H^0} - M^2_A \), respectively. Finally, for the study of the CPC case, one may choose one of the following two equivalent sets:

\[
\mathcal{I}_{\text{CPC}} = \{ v, Y_2; M_{H^\pm}, M_h, M_{H^0}, M_A, \gamma; Z_2, Z_7 \},
\]

\[
\mathcal{I}'_{\text{CPC}} = \{ v; M_{H^\pm}, M_h, M_{H^0}, M_A, \gamma; Z_3, Z_2, Z_7 \},
\]

(23)

each of which contains 9 real degrees of freedom, and the convention of \( |\gamma| \leq \pi/2 \) without loss of generality resulting in \( c_\gamma \geq 0 \) and \( \text{sign}(s_\gamma) = \text{sign}(Z_6) \) if \( M_H > M_h \) GeV.

In the presence of non-vanishing \( \text{Im} Z_5 \) and/or \( \text{Im} Z_6 \), the mixing between the two CP-even states \( \varphi_{1,2} \) and the CP-odd one \( a \) arises leading to CP violation in the neutral Higgs sector. By introducing a rotation \( H_2 \rightarrow e^{i\xi} H_2 \), we note that the Higgs potential given by Eq. (24) is invariant under the following phase rotations:

\[
H_2 \rightarrow e^{+i\xi} H_2; \quad Y_3 \rightarrow Y_3 e^{-i\xi}, \quad Z_5 \rightarrow Z_5 e^{-2i\xi}, \quad Z_6 \rightarrow Z_6 e^{-i\xi}, \quad Z_7 \rightarrow Z_7 e^{-i\xi}.
\]

(24)

Considering the tadpole conditions Eq. (10), this might imply that one of the CP phases of \( \text{Im}(Z_5) \), \( \text{Im}(Z_6) \), and \( \text{Im}(Z_7) \) can be rotated away by rephasing the Higgs fields \( H_2 \). By keeping \( \text{Im}(Z_7) \) as an independent input and taking either \( \text{Im}(Z_5) = 0 \) or \( \text{Im}(Z_6) = 0 \) when \( M_{H_{1,2,3}} \) and \( \omega (\eta) \) are given. More explicitly, using the relations in Eq. (10), we have

\[
\text{Im}(Z_5) = \left[ \frac{M^2_{H^2} s^2_\omega + M^2_{H^0} s^2_\omega - M^2_{H^1}}{v^2} \right] c_\gamma c_\omega s_\gamma - \frac{M^2_{H^2} - M^2_{H^1}}{v^2} c_\gamma c_\omega s_\gamma,
\]

\[
\text{Im}(Z_6) = \left[ \frac{M^2_{H^2} s^2_\omega + M^2_{H^0} s^2_\omega - M^2_{H^1}}{v^2} \right] c_\gamma s_\eta + \frac{M^2_{H^2} - M^2_{H^1}}{v^2} s_\gamma c_\omega s_\gamma,
\]

\[
\text{Im}(Z_7) = \left[ \frac{M^2_{H^2} s^2_\omega + M^2_{H^0} s^2_\omega - M^2_{H^1}}{v^2} \right] c_\gamma s_\eta + \frac{M^2_{H^2} - M^2_{H^1}}{v^2} s_\gamma c_\omega s_\gamma,
\]

(26)

parameterizing the mixing matrix \( O \) as follow:

\[
O_{\text{CPV}} = O_\gamma O_\eta O_\omega \equiv \left( \begin{array}{ccc} c_\gamma & s_\gamma & 0 \\ -s_\gamma & c_\gamma & 0 \\ 0 & 0 & 1 \end{array} \right) \left( \begin{array}{ccc} c_\eta & 0 & s_\eta \\ 0 & 1 & 0 \\ -s_\eta & 0 & c_\eta \end{array} \right) \left( \begin{array}{ccc} 1 & 0 & 0 \\ 0 & c_\omega & s_\omega \\ 0 & -s_\omega & c_\omega \end{array} \right)
\]

\[
= \left( \begin{array}{ccc} c_\gamma c_\eta & s_\gamma c_\eta - c_\gamma s_\eta s_\omega & s_\gamma s_\eta c_\omega + c_\gamma s_\eta c_\omega \\ -s_\gamma c_\eta & s_\gamma c_\eta + s_\gamma s_\eta s_\omega & c_\gamma s_\eta c_\omega - s_\gamma s_\eta c_\omega \\ 0 & -s_\omega c_\eta & c_\eta c_\omega \end{array} \right).
\]

(27)

Assuming \( c_\eta \neq 0 \) and, for example, taking \( \gamma \) and \( \omega \) as the input mixing angles, the remaining mixing angle \( \eta \) is determined by

\[
s_\eta \mid \text{Im} Z_5 = 0 = \frac{(M^2_{H^2} - M^2_{H^1}) c_\gamma c_\omega s_\omega}{(M^2_{H^2} s^2_\omega + M^2_{H^0} s^2_\omega - M^2_{H^1}) s_\gamma}.
\]

(28)

imposing \( \text{Im} Z_5 = 0 \). If \( \text{Im} Z_6 = 0 \) is imposed instead, \( \eta \) is determined by

\[
s_\eta \mid \text{Im} Z_6 = 0 = -\frac{(M^2_{H^2} - M^2_{H^1}) s_\gamma c_\omega s_\omega}{(M^2_{H^2} s^2_\omega + M^2_{H^0} s^2_\omega - M^2_{H^1}) c_\gamma}.
\]

(29)

\[\text{9 Or, equivalently, } \mathcal{H}_1^\dagger H_2 \rightarrow e^{i\xi} \mathcal{H}_1^\dagger H_2.\]

\[\text{10 In this CP-violating (CPV) case, we parameterize the mixing matrix } O \text{ by introducing the three mixing angles of } \gamma, \eta, \text{ and } \omega \text{ as explicitly shown in Eq. (27).}\]
Of course, using $Z_3$ instead of $Y_2$, one may use the alternative set
\[ T_{\text{CPV}} = \{ v; M_{H^\pm}, M_{H_1}, M_{H_2}, M_{H_3}, \gamma, \{ \omega \text{ or } \eta \}; Z_3; Z_2, \Re(Z_7), \Im(Z_7) \} . \] (30)

Incidentally, one may choose the basis in which $\Im(Z_7) = 0$ by taking the following set of input parameters:
\[ T''_{\text{CPV}} = \{ v; M_{H^\pm}, M_{H_1}, M_{H_2}, \gamma, \eta, \omega; Z_3; Z_2, Z_7 \} , \] (31)
where all the three mixing angles are independent from one another and $Z_7$ is real.

In passing, we note that, in the limit of $c_\gamma = 1$ and $s_\eta = 0$, the mixing matrix takes the simpler form
\[ O_{\text{CPV}}|_{\sin \gamma = 0} = O_\eta O_\omega = \begin{pmatrix} c_\eta & -s_\eta s_\omega & s_\eta c_\omega \\ c_\omega & s_\eta & s_\omega \\ -s_\eta & -c_\eta s_\omega & c_\eta c_\omega \end{pmatrix} . \] (32)

When $c_\eta \simeq 1 - \eta^2/2$ and $s_\eta \simeq \eta$, the lightest $H_1$ is SM like and the heavier ones $H_{2,3}$ are mostly arbitrary mixtures of $\varphi_2$ and $a$. On the other hand, when $c_\eta \simeq |\eta|$ and $|s_\eta| \simeq 1 - \eta^2/2$, the lightest $H_1$ is mostly CP odd ($H_1 \sim a$) and $H_2$ ($H_3$) is SM like when $|s_\omega| \simeq 1$ ($|c_\omega| \simeq 1$).

C. Yukawa Couplings in Higgs basis

In the 2HDM, the Yukawa couplings might be given by \[ 34 \]
\[ \mathcal{L}_Y = \sum_{k=1,2} \bar{Q}^k_L y^u_k \tilde{H}_k u^0_R + \bar{Q}^k_L y^d_k \tilde{H}_k d^0_R + \bar{L}^0_k y^e_k \tilde{H}_k e^0_R + \text{h.c.} \] (33)
in terms of the six $3 \times 3$ Yukawa matrices $y_{i,2}^{u,d,e}$ with the electroweak eigenstates $Q^0_L = (u^0_L, d^0_L)^T$, $L^0_L = (u^0_L, e^0_L)^T$, $\nu^0_R$, $d^0_R$, and $e^0_R$. The two Higgs doublets $H_{1,2}$ in the Higgs basis are given by Eq. (6):
\[ H_1 = \left( G^+, \frac{1}{\sqrt{2}} (v + \varphi_1 + iG^0) \right)^T, \quad H_2 = \left( H^+, \frac{1}{\sqrt{2}} (\varphi_2 + iG^0) \right)^T, \] (34)
and their SU(2)-conjugated doublets by
\[ \tilde{H}_1 = i\tau_2 H^*_1 = \left( \frac{1}{\sqrt{2}} (v + \varphi_1 - iG^0), -G^- \right)^T, \quad \tilde{H}_2 = i\tau_2 H^*_2 = \left( \frac{1}{\sqrt{2}} (\varphi_2 - iG^0), -H^- \right)^T. \] (35)
The Yukawa interactions include the following mass terms
\[ -\mathcal{L}_{Y,\text{mass}} = \frac{v}{\sqrt{2}} \left( \bar{u}^T_L y^u_1 u^0_R + \bar{d}^T_L y^d_1 d^0_R + \bar{e}^T_L y^e_1 e^0_R + \text{h.c.} \right) , \] (36)
which involve only the Yukawa matrices of $y_{i,2}^{u,d,e}$. Therefore, introducing two unitary matrices relating the left/right-handed electroweak eigenstates $f^0_{L,R}$ to the left/right-handed mass eigenstates $f_{L,R}$ with $f = u, d, e$ as follows
\[ u^0_L = U_{uL} u_L, \quad d^0_L = U_{dL} d_L, \quad e^0_L = U_{eL} e_L ; \]
\[ u^0_R = U_{uR} u_R, \quad d^0_R = U_{dR} d_R, \quad e^0_R = U_{eR} e_R , \] (37)
we have, for the mass terms,
\[ -\mathcal{L}_{Y,\text{mass}} = \bar{u}^T_L M_u u_R + \bar{d}^T_L M_d d_R + \bar{e}^T_L M_e e_R + \text{h.c.} , \] (38)
where the three diagonal matrices are

\[
\begin{align*}
M_u &= \frac{v}{\sqrt{2}} U_{u_L}^\dagger y_u^L U_{u_R} = \text{diag}(m_u, m_c, m_t), \\
M_d &= \frac{v}{\sqrt{2}} U_{d_L}^\dagger y_d^L U_{d_R} = \text{diag}(m_d, m_s, m_b), \\
M_e &= \frac{v}{\sqrt{2}} U_{e_L}^\dagger y_e^L U_{e_R} = \text{diag}(m_e, m_\mu, m_\tau),
\end{align*}
\]

in terms of the six quark and three charged-lepton masses. We note that \(U_{u_L}^\dagger U_{d_L} = V_{\text{CKM}} \equiv V\) is nothing but the CKM matrix and, by the use of it, the SU(2)_L quark doublets in the electroweak basis can be related to those in the mass basis in the following two ways:

\[
Q_L^0 = U_{u_L} \begin{pmatrix} u_L \\ V d_L \end{pmatrix} \quad \text{or} \quad Q_L^1 = U_{d_L} \begin{pmatrix} V^\dagger u_L \\ d_L \end{pmatrix}. \tag{40}
\]

The first relation is used for the Yukawa interactions with the right-handed up-type quarks and the second one for those with the right-handed down-type quarks. Incidentally, we also have

\[
F_L^0 = U_{e_L} \begin{pmatrix} \nu_L \\ e_L \end{pmatrix} \tag{41}
\]

by defining \(\nu_L \equiv U_{e_L}^\dagger \nu_L^0\) with no physical effects in the case with vanishing neutrino masses.

Collecting all the parameterizations, unitary rotations, and re-parameterizations, the couplings of the neutral Higgs bosons to two fermions are given by

\[
-\mathcal{L}_{Hff} = \frac{1}{v} \left[ \overline{\mathbf{M}_u} u \right] \varphi_1 + \left[ \overline{\mathbf{M}_d} d \right] \varphi_2 + \left[ \overline{\mathbf{M}_e} e \right] \varphi_3
\]

\[
+ \frac{1}{v} \left[ \overline{d M_d} d \right] \varphi_1 + \left[ \overline{d (h^H_d + h^A_d \gamma_5)} d \right] \varphi_2 + \left[ \overline{e (h^H_e + h^A_e \gamma_5)} e \right] \varphi_3
\]

\[
+ \frac{1}{v} \left[ \overline{e M_e} e \right] \varphi_1 + \left[ \overline{e (h^H_e + h^A_e \gamma_5)} e \right] \varphi_2 + \left[ \overline{e (h^A_e + i h^H_e \gamma_5)} e \right] \varphi_3 \tag{42}
\]

where three Hermitian and three anti-Hermitian Yukawa coupling matrices are

\[
\mathbf{h}_f^H \equiv \frac{h_f + h_f^\dagger}{2}, \quad \mathbf{h}_f^A \equiv \frac{h_f - h_f^\dagger}{2}, \tag{43}
\]

with \(h_f = u, d, e\) given in terms of the \(3 \times 3\) Yukawa matrix \(y_2^f\) and two unitary matrices as

\[
\mathbf{h}_f \equiv \frac{1}{\sqrt{2}} \mathbf{U}_{f_L}^\dagger y_2^f U_{f_R}. \tag{44}
\]

We observe that the couplings of the \(\varphi_1\) field are diagonal in the flavor space and their sizes are directly proportional to the masses of the fermions to which it couples. In contrast, those of the \(\varphi_2\) and \(a\) fields are not diagonal in the flavor space leading to the tree-level Higgs-mediated FCNC and their magnitudes are arbitrary in principle.

To avoid the tree-level FCNC, the matrices \(h_f = u, d, e\) are desired to be diagonal which can be achieved by requiring \(^\[11\]\)

\[
\mathbf{y}_2^f = \zeta_f y_1^f, \tag{45}
\]

along with introducing the three complex alignment parameters \(\zeta_f = u, d, e\). In this case, the two aligned Yukawa matrices \(y_1^f\) and \(y_2^f\) can be diagonalized simultaneously and the Yukawa matrices describing the couplings of \(\varphi_2\) and \(a\) fields

\[\text{References}\]

\(^\[11\] Under this requirement, the Yukawa matrix \(\mathbf{h}_f\) for the Higgs field \(\mathcal{H}_2\) is indeed diagonal with its diagonal components being proportional to the hierarchical fermion masses multiplied by the common factor \(\zeta_j\), see Eq. \(^\[10\]\). For an alternative Yukawa alignment in which \(\mathcal{H}_2\) can couple to light fermions sizably while still achieving the absence of tree-level FCNCs, see Ref. \(^\[10\]\).
TABLE I. Classification of the conventional 2HDMs satisfying the Glashow-Weinberg condition which guarantees the absence of tree-level Higgs-mediated flavor-changing neutral current (FCNC). For the four types of 2HDM, we follow the conventions found in, for example, Ref. [103].

|        | 2HDM I | 2HDM II | 2HDM III | 2HDM IV |
|--------|--------|---------|----------|---------|
| ζ_u    | 1/|t_β | 1/|t_β | 1/|t_β | 1/|t_β |
| ζ_d    | 1/|t_β | -|t_β | 1/|t_β | -|t_β |
| ζ_e    | 1/|t_β | -|t_β | -|t_β | 1/|t_β |
| ζ_d = ζ_e = ζ_u | ζ_d = ζ_e = -1/ζ_u | ζ_d = -1/ζ_e = ζ_u | ζ_d = -1/ζ_e = -1/ζ_u |

Note that the second source is absent in the conventional four types of 2HDMs since with the scalar and pseudoscalar couplings given by Eq. (49) are invariant under the phase rotations given by Eq. (52) as they should be. To be in terms of the complex alignment parameters. Then one may be able to show that the scalar and pseudoscalar couplings given by Eq. (49) are invariant under the phase rotations given by Eq. (52) as they should be. To be

to the fermion mass eigenstates are given by

\[ h_f = \zeta_f \frac{M_f}{v}, \quad (46) \]

which leads to the Hermitian and anti-Hermitian Yukawa matrices

\[ h_f^H = \Re(\zeta_f) \frac{M_f}{v}, \quad h_f^A = i \Im(\zeta_f) \frac{M_f}{v}. \quad (47) \]

When \( \Im(\zeta_f) = 0 \), the conventional 2HDMs based on the Glashow-Weinberg condition can be obtained by choosing \( \zeta_f \) as shown in Table I. Otherwise, the couplings of the mass eigenstates of the neutral Higgs bosons to two fermions are given by

\[ -\mathcal{L}_{H_f} = \sum_{i=1}^{3} \sum_{j=\text{u,d,c,s,t,b,e,µ,τ}} \sum_{a=1}^{3} \frac{m_j}{v} \bar{f} \left( g_{H,f}^S + i g_{H,f}^P \right) f H_i \quad (48) \]

with the scalar and pseudoscalar couplings given by

\[ g_{H,f}^S = |O_{\varphi_1}|O_{\varphi_2} \pm \Im(\zeta_f)O_{\alpha_1}, \]

\[ g_{H,f}^P = \Im(\zeta_f)O_{\varphi_2} \mp \Re(\zeta_f)O_{\alpha_1}, \quad (49) \]

where the upper and lower signs are for the up-type fermions \( f = u, c, t \) and the down-type fermions \( f = d, s, b, e, µ, τ \), respectively. The simultaneous existence of the scalar \( g_{H,f}^S \) and pseudoscalar \( g_{H,f}^P \) couplings for a specific \( H_i \) signals the CP violation in the neutral Higgs sector. We figure out that there are two different sources of the neutral Higgs-sector CP violation: (i) one is the CP-violating mixing among the CP-even and CP-odd states arising in the presence of non-vanishing \( \Im(Z_{5,6}) \) in the Higgs potential and (ii) the other one is the complex alignment parameters of \( \zeta_f \)'s. Note that the second source is absent in the conventional four types of 2HDMs since \( \zeta_f \)'s are real in those models.

The couplings of charged Higgs bosons to two fermions are given by

\[ -\mathcal{L}_{H^\pm f} = -\sqrt{2} \left[ \bar{\pi}(h_{\mu}V)d_L \right] H^+ + \sqrt{2} \left[ \bar{\pi}(V h_d) d_R \right] H^+ + \sqrt{2} \left[ \bar{\pi}_{\nu e} e_R \right] H^+ + \text{h.c.} \quad (50) \]

in terms of the CKM matrix \( V \) and the \( 3 \times 3 \) Yukawa matrices \( h_{u,d,e} \).

Previously, we note that the Higgs potential given by Eq. (5) is invariant under the phase rotation \( H_2 \rightarrow e^{i\zeta}H_2 \) if the complex potential parameters are accordingly rephased, see Eq. (24). This observation extends to the Yukawa interactions, Eq. (33), by noting that they are invariant under the phase rotations:

\[ H_2 \rightarrow e^{i\zeta}H_2; \quad y_2^u \rightarrow e^{i\zeta}y_2^u, \quad y_2^d \rightarrow e^{-i\zeta}y_2^d, \quad y_2^e \rightarrow e^{-i\zeta}y_2^e. \quad (51) \]

Under the alignment assumption \( y_2^f = \zeta_f y_1^f \) given by Eq. (45), the above rephasing invariant rotations become

\[ H_2 \rightarrow e^{i\zeta}H_2; \quad \zeta_u \rightarrow e^{i\zeta}\zeta_u, \quad \zeta_d \rightarrow e^{-i\zeta}\zeta_d, \quad \zeta_e \rightarrow e^{-i\zeta}\zeta_e, \quad (52) \]

in terms of the complex alignment parameters. Then one may be able to show that the scalar and pseudoscalar couplings given by Eq. (49) are invariant under the phase rotations given by Eq. (52) as they should be. To be
explicit, we first note that, under the phase rotation $H_2 \to e^{i\zeta} H_2$, the electroweak Higgs basis changes as follow:

\[
\begin{pmatrix}
\varphi_1 \\
\varphi_2 \\
a
\end{pmatrix}
\to
O^T \begin{pmatrix}
\varphi_1 \\
\varphi_2 \\
a
\end{pmatrix}
\quad \text{with} \quad O_\zeta = \begin{pmatrix}
1 & 0 & 0 \\
0 & c_\zeta & s_\zeta \\
0 & -s_\zeta & c_\zeta
\end{pmatrix},
\]

(53)

which leads to

\[O \to O^T_\zeta O; \quad M_0^2 \to O^T_\zeta M_0^2 O_\zeta\]

(54)

by observing that $(H_1, H_2, H_3)^T = O^T (\varphi_1, \varphi_2, a)^T$ and $\text{diag}(M_{H_1}^2, M_{H_2}^2, M_{H_3}^2) = O^T M_0^2 O$ should remain the same, respectively. Under the transformation $O \to O^T_\zeta O$, the components of the mixing matrix $O$ change into

\[O_{\varphi_1,i} \to O_{\varphi_1,i}, \quad O_{\varphi_2,i} \to c_\zeta O_{\varphi_2,i} - s_\zeta O_{ai}, \quad O_{ai} \to s_\zeta O_{\varphi_2,i} + c_\zeta O_{ai}.
\]

(55)

On the other hand, under the rotations $\zeta_f \to e^{\pm i\zeta} \zeta_f$ given in Eq. (52), one may have

\[\Re(\zeta_f) \to c_\zeta \Re(\zeta_f) \mp s_\zeta \Im(\zeta_f), \quad \Im(\zeta_f) \to c_\zeta \Im(\zeta_f) \mp s_\zeta \Re(\zeta_f),
\]

(56)

with the upper and lower signs being for the up-type massive fermions $f = u, d, e$ and the down-type massive fermions $f = d, e$, respectively. Using Eqs. (55) and (56), it is straightforward to show that the scalar and pseudoscalar couplings given by Eq. (49) are invariant under the phase rotations of Eq. (52).

To summarize, assuming $y_i^2 = \zeta_f y_1^f$ with $\zeta_f = u, d, e$ being the three complex alignment parameters and combining Eqs. (24) and (52), we note that the Higgs potential and the Yukawa interactions are invariant under the following phase rotations:

\[
\begin{align*}
H_2 & \to e^{+i\zeta} H_2; \\
Y_3 & \to Y_3 e^{-i\zeta}, \\
Z_5 & \to Z_5 e^{-2i\zeta}, \\
Z_6 & \to Z_6 e^{-i\zeta}, \\
Z_7 & \to Z_7 e^{-i\zeta}; \\
\zeta_u & \to \zeta_u e^{+i\zeta}, \\
\zeta_d & \to \zeta_d e^{-i\zeta}, \\
\zeta_e & \to \zeta_e e^{-i\zeta}.
\end{align*}
\]

(57)

which, taking account of the CP odd tadpole condition $Y_3 + Z_6 v^2/2 = 0$, lead to five rephasing-invariant CPV phases in total. This leaves us more freedom to choose the input parameters for the Higgs potential other than $T_{\text{CPV}}$, $T'_{\text{CPV}}$, or $T''_{\text{CPV}}$. For example, one may assign three CPV phases to the Higgs potential and take $\zeta_u$ real and positive definite. In this case, the full set of input parameter is to be

\[
T_{\text{CPV}}^{Y_1 @ \text{Yukawa}} \bigg|_{\zeta_u > 0, \Im(\zeta_u) = 0} = \{v, M_{H^\pm}, M_{H_1}, M_{H_2}, M_{H_3}, \gamma, \eta, \omega; Z_3, Z_2, Z_7\} \oplus \{|\zeta_u|, |\zeta_d|, |\zeta_e|\},
\]

(58)

which contains 12 and 5 real degrees of freedom in the Higgs potential and the Yukawa interactions, respectively, with $Z_7, \zeta_d$ and $\zeta_e$ being fully complex.

### D. Interactions with Massive Vector Bosons

The cubic interactions of the neutral and charged Higgs bosons with the massive gauge bosons $Z$ and $W^\pm$ are described by the three interaction Lagrangians:

\[
\mathcal{L}_{HVV} = g M_W \left( W^\mu_+ W^-\mu + \frac{1}{2c_W} Z_\mu Z^\mu \right) \sum_i g_{H_i, VV} H_i,
\]

\[
\mathcal{L}_{HHZ} = \frac{g}{2c_W} \sum_{i>j} g_{H_i, H_j, Z} Z^\mu (H_i \partial_\mu H_j),
\]

\[
\mathcal{L}_{HHZ^\mp W_\mp} = -\frac{g}{2} \sum_i g_{H_i, H^+ - W^-} W^-\mu (H_i \partial_\mu H^+) + \text{h.c.},
\]

(59)

respectively, where $X \overset{\leftrightarrow}{\partial_\mu} Y = X \partial_\mu Y - (\partial_\mu X) Y$, $i, j = 1, 2, 3$ and the normalized couplings $g_{H_i, VV}$, $g_{H_i, H_j, Z}$ and $g_{H_i, H^+ - W^-}$ are given in terms of the neutral Higgs-boson $3 \times 3$ mixing matrix $O$ by (note that $\text{det}(O) = \pm 1$ for any
orthogonal matrix $O$:

$$g_{H_{i}V V} = O_{i i},$$

$$g_{H_{i}H_{j}V V} = \text{sign}[\det(O)] \epsilon_{ijk} g_{H_{k}V V} = \text{sign}[\det(O)] \epsilon_{ijk} O_{i k},$$

$$g_{H_{i}H_{i}W^+W^-} = -O_{i 2i} + iO_{ai},$$

leading to the following sum rules:

$$\sum_{i=1}^{3} g_{H_{i}V V}^2 = 1 \quad \text{and} \quad g_{H_{i}V V}^2 + |g_{H_{i}V V}|^2 = 1 \quad \text{for each} \ i = 1, 2, 3. \quad (60)$$

On the other hand, the quartic interactions of the neutral and charged Higgs bosons with the massive gauge bosons $Z$ and $W^\pm$ and massless photons are given by

$$\mathcal{L}_{HHVV} = \frac{1}{v^2} \left( M_0^2 W^\mu W^\mu + \frac{M_Z^2}{2} Z^\mu Z^\mu \right) \sum_{i,j=1}^{3} g_{H_{i}H_{j}V V} H_i H_j, \quad (62)$$

with $g_{H_{i}H_{j}V V} = \delta_{ij}$ and

$$\mathcal{L}_{H^+H^-V V} = \left( \frac{g^2}{2} W^\mu W^\mu + \frac{g_Z^2}{4} Z^\mu Z^\mu + e^2 A^\mu A^\mu + e g_Z \frac{g^2}{2} W^\mu Z^\mu \right) H^+ H^-,$$

$$\mathcal{L}_{H^\pm H^\mp Z^\pm} = \frac{g_Z g_Z^2}{2} \left( Z^\mu W^{-\mu} \sum_{i=1}^{3} g_{Z W^{-}H_i} H^+ H_i + \text{h.c.} \right),$$

$$\mathcal{L}_{H^\pm H^\mp A^\mp} = -\frac{e g}{2} \left( A^\mu W^{-\mu} \sum_{i=1}^{3} g_{A W^{-}H_i} H^+ H_i + \text{h.c.} \right), \quad (63)$$

with $g_{Z W^{-}H_i} = g_{A W^{-}H_i} = -O_{i 2i} - iO_{ai}$, $c_{2W} = \cos2\theta_W$, and $g_Z = g/c_W = e/(s_W c_W)$.

### III. CONSTRAINTS

In this Section, we consider the perturbative unitarity (UNIT) conditions and those for the Higgs potential to be bounded from below (BFB) to obtain the primary theoretical constraints on the potential parameters or, equivalently, the constraints on the Higgs-boson masses including correlations among them and the mixing among the three neutral Higgs bosons. We further consider the constraints on the Higgs masses and their couplings with vector bosons taking into account the electroweak oblique corrections to the so-called $S$ and $T$ parameters. We emphasize that all the three types of constraints from the perturbative unitarity, the Higgs potential bounded from below, and the electroweak precision observables (EWPOs) are independent of the basis chosen and working in the Higgs basis does not invoke any restrictions. We also consider the constraints on $|\zeta_2|$, $|\zeta_3|$, and the product of $\zeta_2 \zeta_3$ taking account of the charged Higgs contributions to the flavor-changing $\tau$ decays into light leptons, $Z \to b\bar{b}$, $\epsilon_K$, and $b \to s\gamma$ \text{[96, 106, 109]}.

#### A. Perturbative Unitarity

For the unitarity conditions, we closely follow Ref. \text{[108, 109]} considering the three scattering matrices of $\mathcal{M}_{1,2,3}$ which are expressed in terms of the quartic couplings $Z_{1-7}$, see also Ref. \text{[109]}. The two $4 \times 4$ real and symmetric scattering matrices $\mathcal{M}_1^S$ and $\mathcal{M}_2^S$ are given by

$$\mathcal{M}_1^S = \begin{pmatrix} \eta_{00} - I & \eta^T \\ \eta & E + I \times 1_{3 \times 3} \end{pmatrix}; \quad \mathcal{M}_2^S = \begin{pmatrix} 3\eta_{00} - I & 3\eta^T \\ 3\eta & 3E + I \times 1_{3 \times 3} \end{pmatrix}, \quad (64)$$

\text{12 We refer to, for example, Ref. \text{[107]} for an extensive study of flavor observables in the conventional 2HDMs taking the $\Phi$ basis.}

\text{13 We keep our conventions for the potential parameters.}
where \( \eta_{00} = Z_1 + Z_2 + Z_3 \) and \( I = Z_3 - Z_4 \). The row vector \( \eta^T \) is given by
\[
\eta^T = (\Re(Z_6 + Z_7), -3\Im(Z_6 + Z_7), Z_1 - Z_2),
\]
and the \( 3 \times 3 \) real and symmetric matrix \( E \) by
\[
E = \begin{pmatrix}
Z_4 + 2\Re(Z_5) & -2\Im(Z_5) & \Re(Z_6 - Z_7) \\
-2\Im(Z_5) & Z_4 - 2\Re(Z_5) & -3\Im(Z_6 - Z_7) \\
\Re(Z_6 - Z_7) & -3\Im(Z_6 - Z_7) & Z_1 + Z_2 - Z_3
\end{pmatrix}.
\]
(66)

The third \( 3 \times 3 \) scattering matrix \( M_3^S \) is Hermitian which takes the form of
\[
M_3^S = \begin{pmatrix}
2Z_1 & 2Z_5 & \sqrt{2}Z_6 \\
2Z_5^* & 2Z_2 & \sqrt{2}Z_7^* \\
\sqrt{2}Z_6^* & \sqrt{2}Z_7^* & Z_3 + Z_4
\end{pmatrix}.
\]
(67)

And then, the unitarity conditions are imposed by requiring that the 11 eigenvalues of the three scattering matrices \( M_{1,2,3} \) and the quantity \( I \) should have their moduli smaller than \( 4\pi \).

When \( Z_6 = Z_7 = 0 \), the 12 unitarity conditions simplify into
\[
|Z_3 \pm Z_4| < 4\pi, \\
|Z_3 \pm 2|Z_5|| < 4\pi, \\
|Z_3 + 2Z_4 \pm 6|Z_5|| < 4\pi, \\
|Z_1 + Z_2 \pm \sqrt{(Z_1 - Z_2)^2 + 4|Z_5|^2}| < 4\pi, \\
|Z_1 + Z_2 \pm \sqrt{(Z_1 - Z_2)^2 + Z_4^2}| < 4\pi, \\
|3Z_1 + 3Z_2 \pm \sqrt{9(Z_1 - Z_2)^2 + (2Z_4 + Z_4)^2}| < 4\pi.
\]
(68)

While taking \( Z_1 = Z_2 = Z_3 = Z_4 = Z_5 = 0 \), one may have
\[
\sqrt{|Z_6|^2 + |Z_7|^2} < 2\sqrt{2}\pi, \\
\sqrt{|Z_6|^2 + |Z_7|^2 + |Z_6^2 + Z_7^2|} < \frac{4\pi}{3}.
\]
(69)

Then, by combining them, one may arrive at the following UNIT conditions for individual parameters \[108\]
\[
|Z_{1,2,5}| < 2\pi/3, \quad |Z_{6,7}| < 2\sqrt{2}\pi/3, \\
|Z_3 - Z_4| < 4\pi \cup |2Z_3 + Z_4| < 4\pi \cup |Z_3 + 2Z_4| < 4\pi.
\]
(70)

### B. Higgs Potential Bounded-from-below

We consider the following 5 necessary conditions for the most general 2HDM Higgs potential with explicit CP violation to be bounded-from-below in a marginal sense \[108\]:
\[
Z_1 \geq 0, \quad Z_2 \geq 0; \\
2\sqrt{Z_1Z_2} + Z_3 \geq 0, \quad 2\sqrt{Z_1Z_2} + Z_3 + Z_4 - 2|Z_5| \geq 0; \\
Z_1 + Z_2 + Z_3 + Z_4 + 2|Z_5| - 2|Z_6 + Z_7| \geq 0.
\]
(71)

Note that though the quartic couplings \( Z_2 \) and \( Z_7 \) have no direct relations to the masses and mixing of Higgs bosons but they are interrelated with the other five quartic couplings of \( Z_{1,3-6} \) through the UNIT and BFB conditions.

---

\[14\] Denoting the quartic part of the scalar potential as \( V_4 \), a marginal stability requirement means that \( V_4 \geq 0 \) for any direction in field space tending to infinity \[109\]. In contrast, a strong stability requirement is \( V_4 > 0 \) without the equality sign. In this work, we adopt the marginal stability requirement.
C. Electroweak Precision Observables

The electroweak oblique corrections to the so-called $S$, $T$, and $U$ parameters [110, 111] provide significant constraints on the quartic couplings of the 2HDM. Fixing $U = 0$ which is suppressed by an additional factor $M_Z^2/M_{BSM}^2$ [15] compared to $S$ and $T$, the $S$ and $T$ parameters are constrained as follows

$$
\frac{(S - \tilde{S}_0)^2}{\sigma_S^2} + \frac{(T - \tilde{T}_0)^2}{\sigma_T^2} - 2\rho_{ST} \frac{(S - \tilde{S}_0)(T - \tilde{T}_0)}{\sigma_S \sigma_T} \leq R^2 (1 - \rho_{ST}^2),
$$

(72)

with $R^2 = 2.3, 4.61, 5.99, 9.21, 11.83$ at 68.3%, 90%, 95%, 99%, and 99.7% confidence levels (CLs), respectively. For our numerical analysis, we adopt the 95% CL limits. The central values and their standard deviations are given by [16]

$$
(S_0, \sigma_S) = (0.00, 0.07), \quad (T_0, \sigma_T) = (0.05, 0.06),
$$

(73)

with a strong correlation $\rho_{ST} = 0.92$ between $S$ and $T$ parameters. The electroweak oblique parameters, which are defined to arise from new physics only, are in excellent agreement with the SM values of zero for the reference values of $M_{BSM} = 125.25$ GeV and $M_t = 172.5$ GeV [112].

In 2HDM, the $S$ and $T$ parameters might be estimated using the following expressions [113, 114]

$$
S_\Phi = -\frac{1}{4\pi} \left(3 + \frac{\delta_{H^2}^Z}{\gamma^Z} \right)^2 F_\Delta(M_{H^\pm}, M_{H^\pm}) - \sum_{i,j=1}^{(1,3),(2,3)} \left(g_{H_i H_j z} + \delta_{H_i H_j}^z \right)^2 F_\Delta(M_{H_i}, M_{H_j}),
$$

$$
T_\Phi = -\frac{\sqrt{2} G_F}{16\pi^2 \alpha_{EM}} \left[ -\sum_{i=1}^{3} \left| g_{H_i H^{-+} z} + \delta_{H_i}^z \right|^2 F_\Delta(M_{H_i}, M_{H^\pm}) + \sum_{i,j=1}^{(1,3),(2,3)} \left(g_{H_i H_j z} + \delta_{H_i H_j}^z \right)^2 F_\Delta(M_{H_i}, M_{H_j}) \right].
$$

(74)

In this work, we ignore the vertex corrections $\delta_{H^2}^Z$, $\delta_{H_i}^z$, and $\delta_{H_i H_j}^z$ since the size of the most of the quartic couplings are smaller than 3 and the quantum corrections proportional to $\sim Z_i^2/16\pi^2$ might be negligible. Then, we observe that all the relevant couplings are determined by the three physical couplings of $g_{H_i H_j z}$ since $g_{H_i H_j z}^2 = |\epsilon_{ij}|^2 g_{H_i H_j}^2 = |\epsilon_{ij}|^2 (1 + 3\delta_{ij})$. The one-loop functions are given by [17]

$$
F_\Delta(m_0, m_1) = F_\Delta(m_1, m_0) = \frac{m_0^2 + m_1^2}{2} - \frac{m_0^2 m_1^2}{m_0^2 - m_1^2} \ln \frac{m_0^2}{m_1^2},
$$

$$
F_\Delta'(m_0, m_1) = F_\Delta'(m_1, m_0) = -\frac{1}{3} \left[ 4 \ln m_0^2 - m_1^2 \ln m_1^2 \right] - \frac{m_0^2 + m_1^2}{(m_0^2 - m_1^2)^2} F_\Delta(m_0, m_1).
$$

(75)

We note that $F_\Delta(m, m) = 0$ and $F_\Delta'(m, m) = \frac{1}{3} \ln m^2$. [18] When $g_{H_i H_j}^2 = 1$, neglecting the $Z^2$-dependent vertex correction factors $\delta_{H_i}^z$ and $\delta_{H_i H_j}^z$, $S_\Phi$ and $T_\Phi$ are symmetric under the exchange $M_{H_2} \leftrightarrow M_{H_3}$ and they are identically vanishing when $M_{H_2} = M_{H_3} = M_{H^\pm}$. [19]

D. Flavor Constraints on the Alignment Parameters

The alignment parameters $\zeta_f = u, d, e$ are constrained by considering the charged Higgs contributions to the low energy observables such as flavor-changing $\tau$ decays, leptonically and semileptonically decays of pseudoscalar mesons, the $Z \to b\bar{b}$ process, $B$ meson mixing, the CPV parameter $\epsilon_K$ in $K$ meson mixing, and the radiative $b \to s\gamma$ decay [90]. In this work, we consider the flavor constraints on the absolute sizes of $\zeta_c$, $\zeta_u$, and $\zeta_d$. Note that we neglect the constraints on the products of the alignment parameters taking account of only the single constraints on the absolute values of $\zeta_c$, $\zeta_u$, and $\zeta_d$ under the assumption that they are fully independent from each other.

15 Here, $M_{BSM}$ denotes some heavy mass scale involved with new physics beyond the Standard Model.

16 See the 2020 edition of the review “10. Electroweak Model and Constraints on New Physics” by J.Erler and A. Freitas in Ref. [112].

17 See, for example, Ref. [115].

18 Here and after, $\ln m^2$ could be understood as, for example, $\ln (m^2/(1\text{ GeV})^2)$ if necessary.

19 The $S_\Phi$ and $T_\Phi$ parameters are independent of $M_{H_1}$ when $g_{H_i H_j}^2 = 1$. 

14
The flavor-changing $\tau$ decays into light leptons provide the following constraint on $|\zeta_e|$ [96]:

$$|\zeta_e| \leq 200 \left( \frac{M_{H^\pm}}{500 \text{ GeV}} \right).$$  \quad (76)

at 95% CL. On the other hand, the constraint on $|\zeta_u|$ may come from the $Z$-peak precision observables involving the $Z \to bb$ decay assuming the quantum corrections to the $Zbb$ vertex beyond the SM is dominated by the charged Higgs contributions. More explicitly, the ratio $R_b = \Gamma(Z \to bb) / \Gamma(Z \to \text{hadrons})$ is used by neglecting the contributions depending on $|\zeta_d|$ which are suppressed by the factor $\overline{m}_t(M_Z)/\overline{m}_b(M_Z) \sim 60$ compared to those depending on $|\zeta_u|$. It turns out that the upper limit on $|\zeta_u|$ linearly increases with $M_{H^\pm}$ as follow [96]:

$$|\zeta_u| \leq 0.72 + 1.19 \left( \frac{M_{H^\pm}}{500 \text{ GeV}} \right) \quad (95\% \text{ CL}).$$  \quad (77)

To be very strict, the above upper limit should be applied only when $|\zeta_d| = 0$. The similar while more direct upper limit $|\zeta_e|$ could be obtained by considering the CPV parameter $\epsilon_K$ in $K$ meson mixing which depends on $|\zeta_u|$ only neglecting the masses of the light $d$ and $s$ quarks. Actually the limit from $\epsilon_K$ is slightly stronger than that from $Z \to bb$ by the amount of about 10% [96]. In this work, for the upper limit on $|\zeta_u|$, we apply the slightly weaker constraint from $Z \to bb$ given by Eq. [77], while considering it valid independently of $\zeta_d$. In passing, for the $\Delta B = 2$ processes mediated by box diagrams with exchanges of $W^\pm$ and/or $H^\pm$ bosons, we note that the leading Willson coefficients which are not suppressed by the light quark mass depend $\zeta_u$ and $\zeta_d$. When $\zeta_d = 0$, one might obtain the similar upper limit on $|\zeta_u|$ as that from $\epsilon_K$ [96].

There is no limit on $\zeta_d$ independently of $\zeta_u$ and/or $\zeta_e$. But one may extract some interesting information on $\zeta_d$ considering the radiative $b \to s \gamma$ decay. Numerically, the decay amplitude can be cast into the following form.
When $\zeta_u \zeta_d$ is negative, the interference with the SM amplitude is always constructive and the product is constrained to be small and, as usual, $|\zeta_d|$ can be significantly larger (smaller) than 1 only when $|\zeta_u|$ is very small (large). On the contrary, if $\zeta_u \zeta_d$ is positive, $|\zeta_d|$ could be large independently of $|\zeta_u|$. In this case, a destructive interference occurs and the experimental constraints can be satisfied when

$$\zeta_u \zeta_d \sim 20 \left( \frac{M_{H^\pm}}{500 \text{ GeV}} \right)^2 .$$

Combining the upper limit on $|\zeta_u|$ given by Eq. (74), we observe that the destructive interference can always occur when

$$|\zeta_d| \gtrsim 20 \frac{\left( \frac{M_{H^\pm}}{500 \text{ GeV}} \right)^2}{0.72 + 1.19 \left( \frac{M_{H^\pm}}{500 \text{ GeV}} \right)} ,$$

and $\zeta_u \zeta_d > 0$. Most generally, allowing $\zeta_u \zeta_d$ to be complex, it turns out that the rough 95% CL upper limit on the absolute value of the product is basically saturated by the relation given by Eq. (79) or

$$|\zeta_u| |\zeta_d| \lesssim 20 \left( \frac{M_{H^\pm}}{500 \text{ GeV}} \right)^2 (95\% \text{ CL}) .$$

For the summary, we present the upper limits on $|\zeta_e|$, $|\zeta_u|$, and $|\zeta_d\zeta_u|$ and the lower limit on $|\zeta_d|$ in Fig. 1.  

Before closing this section, we briefly comment on the constraints from the heavy Higgs boson searches carried out at the LHC. The heavy neutral Higgs bosons have been searched through their decays into $\tau^+\tau^-$ [117–120], $b\bar{b}$ [121], $tt$ [122–124], $WW$ [125], $ZZ$ [126–129], $Zh_{125GeV}$ [130], etc. On the other hand, the charged Higgs boson search channels include the decay modes into $\tau^\pm\nu$ [130], $tb$ [131], $cb$ [132–136], $cs$ [137], and $Wh_{125GeV}$ [130]. Basically, the experimental upper limits on the product of the production cross section and the decay rate into a specific search mode have been analyzed to obtain the allowed parameter space of a specific model. For example, the search in the $\tau^+\tau^-$ final state excludes the presence of a heavy neutral Higgs with $M_A$ below about 1 TeV at 95% CL in the minimal supersymmetric extension of the SM (MSSM) when, depending on scenarios, $\tan\beta \gtrsim 15 \sim 25$ and the exclusion contour reaches up to $M_A = 1.6$ TeV for $\tan\beta = 60$ [118]. While in the aligned 2HDM taken in this work, the Yukawa couplings of the up- and down-type quarks and the charged leptons to heavy Higgs bosons are completely uncorrelated and the interpretation of the experimental limits is much more involved. This is because the three alignment parameters of $\zeta_{u,d,e}$ are independent from each other while all of them are involved in the calculation of the decay rate pertinent to a specific search mode. In principle, one can easily avoid the constraints from, for example, $H/A \rightarrow \tau\tau$ and $H^\pm \rightarrow \tau\nu$ by taking $|\zeta_e| \ll 1$. But it might be still allowed to have $|\zeta_e| \gtrsim 20$ and $M_A < 1$ TeV if one can suppress the branching fraction into $\tau^+\tau^-$ by choosing the other alignment parameters of $\zeta_u$ and $\zeta_d$ appropriately. In this respect, a through analysis of the experimental search results in the framework of aligned 2HDM with three independent alignment parameters deserves an independent full consideration. In this work, we simply assume that the parameter space considered in the next Section could be made more or less safe from the LHC constraints from no observation of significant excess in the heavy Higgs boson searches by judiciously manipulating the three alignment parameters which are otherwise uncertain.

### IV. NUMERICAL ANALYSIS

From the relation $g_{H_1\nu\nu} = O_{\varphi_{11}}$ given in Eq. (60) and the expressions for the $H_i$ couplings to the two SM fermions given in Eq. (49), one might define the Yukawa delay factor $\Delta_{H_1ff}$ by the amount of which the decoupling of the

Note that the product $\zeta_u \zeta_d$ is the rephasing invariant quantity in our convention, see Eq. (52).
In Ref. [140], the authors take several phenomenological constraints as well as theoretical requirements, we refer to Ref. [140] but with a caution.

To have \( I_{\text{CPC}} \) from Eq. [18], we trade \( M_{H^\pm} \) with \( Z_5 \). Note that the dimensionful parameter \( Y_2 \) is irrelevant for the UNIT and BFB constraints.

A. UNIT and BFB constraints

First of all, we consider the UNIT and BFB constraints. Observing that the two conditions depend only on the quartic couplings \( Z_1 \sim Z_7 \), we take the following set of input parameters:

\[
I_{\text{CPC}}^Z = \{ v, Y_2; Z_1, Z_2, Z_3, Z_4, Z_5, Z_6, Z_7 \}.
\]

In the left panel of Fig. [2] we show the scatter plots of \( Z_2 \) versus \( Z_1 \) (upper left), \( Z_4 \) versus \( Z_3 \) (upper right), \( Z_5 \) versus \( Z_1 \) (lower left), and \( Z_7 \) versus \( Z_6 \) (lower right) with the UNIT conditions imposed. For the blue points, the necessary BFB conditions are additionally imposed. Also shown are the points in black which are obtained by requiring only the simplified UNIT conditions in Eqs. [68] and [69]. (Right) The normalized distributions of the quartic couplings obtained by requiring only the UNIT (red) and the combined \( \text{UNIT} \oplus \text{BFB} \) conditions.

Yukawa couplings of the lightest Higgs boson is delayed compared to its coupling to a pair of massive vector bosons:

\[
\Delta_{H_1^f f} \equiv \sqrt{\left( g_{H_1^f f}^g - g_{H_1^f V V}^P \right)^2 + \left( g_{H_1^f f}^P \right)^2} = |\zeta| \left( 1 - g_{H_1^f V V}^2 \right)^{1/2},
\]

where we use the relation \( \sum_{\alpha=e,d,u} O_{\alpha i}^2 = 1 \) for \( i = 1 \). We observe that the delay factor \( \Delta_{H_1^f f} \) defined above is basis-independent and can be generally used even in the CPV case. Anticipating that the impacts on the Yukawa delay factor due to the CP-violating phases of \( Z_5,6,7 \) and \( \zeta_{e,d,u} \) are redundant, we consider the CP-conserving (CPC) case for our numerical study for simplicity. For a recent global analysis of the aligned CPC 2HDM taking account of several phenomenological constraints as well as theoretical requirements, we refer to Ref. [140] but with a caution.

\[ \text{Ref. [140]} \]

\[ \text{Ref. [140]} \]
respectively. We note that the smaller $|Z_6 + Z_7|$ and the positive $Z_3$ values are preferred by further imposing the BFB conditions in addition to the UNIT ones, see Eq. (71).

B. Electroweak constraints

Coming to the electroweak (ELW) constraints, since the oblique corrections are expressed in terms of the masses and couplings of Higgs bosons, it is more natural and convenient to take the following set of input parameters:

$$I_{\text{CPC}}' = \{v; M_{H^\pm}, M_H = M_{H_1}, M_{H_2}, M_A, \gamma; Z_3; Z_2, Z_7\} ,$$

(84)

referring to Eq. (23). In the $I_{\text{CPC}}'$ set, all the massive parameters are physical Higgs masses except $v = (\sqrt{2}G_F)^{-1/2} \simeq 246.22$ GeV. We assume that the neutral state $h = H_1$ is the lightest Higgs boson and plays the role of the SM Higgs boson in the decoupling limit of $s_\gamma = 0$ by taking $M_{H_1} = 125.5$ GeV \cite{76}. And, for the masses of heavy Higgs bosons, we randomly generate their masses squared between $M_{H^\pm}^2$ and $(1.5 \text{ TeV})^2$. For the mixing angle $\gamma$, we take the convention of $|\gamma| \leq \pi/2$ without loss of generality resulting in $c_\gamma \geq 0$ and $\text{sign}(s_\gamma) = \text{sign}(Z_6)$. For the implementation of the UNIT and BFB constraints using the set $I_{\text{CPC}}'$, we recall the quartic couplings $Z_{1,4,5,6}$ in terms of the Higgs masses and the mixing angle $\gamma$ in the CPC case given by Eq. (22).

Using the set $I_{\text{CPC}}'$ for the input parameters in the CPC case, the $S$ and $T$ parameters given by Eq. (74) take the following simpler forms:

$$S_{\Phi}^{\text{CPC}} = -\frac{1}{4\pi} \left[ F_1^a(M_{H^\pm}, M_{H^\pm}) - c_\gamma^2 F_3^a(M_A, M_H) - s_\gamma^2 F_5^a(M_A, M_H) \right] ,$$

$$T_{\Phi}^{\text{CPC}} = \frac{\sqrt{2}G_F}{16\pi^2\alpha_\text{EM}} \left[ F_1^a(M_A, M_{H^\pm}) + c_\gamma^2 F_3^a(M_H, M_{H^\pm}) + s_\gamma^2 F_5^a(M_H, M_{H^\pm}) - c_\gamma^2 F_3^a(M_A, M_H) - s_\gamma^2 F_5^a(M_A, M_H) \right] ,$$

(85)

ignoring the vertex corrections. We observe that $T_{\Phi}^{\text{CPC}}$ is identically vanishing when $M_{H^\pm} = M_A$ and, when $M_{H^\pm} \sim M_A \sim M_H \gg M_h$, we obtain \footnote{For $S_{\Phi}$, note that $[\ln M_A^2/3 + (M_H - M_A)/3M_A] - [\ln M_H^2/3 + (M_A - M_H)/3M_H] \approx (M_H - M_A)^2/9M_A^2$.}

$$S_{\Phi}^{\text{CPC}} \simeq \frac{1}{4\pi} \left[ \frac{\ln M_{H^\pm}^2}{3} - c_\gamma^2 \left( \frac{\ln M_A^2}{3} + \frac{M_H - M_A}{3M_A} \right) - s_\gamma^2 \left( \frac{\ln M_A^2}{3} - \frac{5}{18} \right) \right] ,$$

$$T_{\Phi}^{\text{CPC}} \simeq \frac{\sqrt{2}G_F}{16\pi^2\alpha_\text{EM}} \left[ \frac{2(M_A - M_{H^\pm})^2}{3} + c_\gamma^2 \frac{2(M_H - M_{H^\pm})^2}{3} + s_\gamma^2 \frac{M_{H^\pm}^2}{2} \right. - \left. c_\gamma^2 \frac{2(M_A - M_H)^2}{3} - s_\gamma^2 \frac{M_A^2}{2} \right] ,$$

(86)

keeping the leading terms. To obtain Eq. (86) for the approximated expressions of the $S$ and $T$ parameters, we use

$$F_1^a(m_0, m_1) = \frac{2(m_0 - m_1)^2}{3} - \frac{(m_0 - m_1)^4}{30m_1^2} + O \left[ \frac{(m_0 - m_1)^5}{m_1^3} \right] ,$$

$$F_3^a(m_0, m_1) = \frac{\ln m_1^2}{3} + \frac{(m_0 - m_1)}{3m_1} - \frac{(m_0 - m_1)^2}{30m_1^2} + O \left[ \frac{(m_0 - m_1)^4}{m_1^3} \right] ,$$

(87)

for $m_0 \sim m_1$ and

$$F_5^a(m_0, m_1) = \frac{m_1^2}{2} + \left( \frac{1}{2} + \ln \frac{m_2^2}{m_1^2} \right) m_0^2 + O \left[ \left( \frac{m_2^2}{m_1^2} \right) \ln \frac{m_2^2}{m_1^2} \right] ,$$

$$F_1^a(m_0, m_1) = \frac{\ln m_1^2}{3} - \frac{5}{18} + \frac{2m_0^2}{3m_1^2} + O \left[ \left( \frac{m_2^2}{m_1^2} \right) \ln \frac{m_2^2}{m_1^2} \right] ,$$

(88)

for $m_1 \gg m_0$. 

23 For $S_{\Phi}$, note that $[\ln M_A^2/3 + (M_H - M_A)/3M_A] - [\ln M_H^2/3 + (M_A - M_H)/3M_H] \simeq (M_H - M_A)^2/9M_A^2$. 
In the left panel of Fig. 3, we show the $S$ and $T$ parameters imposing the UNIT, BFB, and ELW constraints abbreviated by the combined UNIT⊕BFB⊕ELW95% ones. Note that the 95% CL ELW limits are adopted and the heavy Higgs masses squared are scanned up to $(1.5 \text{ TeV})^2$. We find that $S$ takes values in the range between $-0.02$ and $0.05$ whose absolute values are smaller than $\sigma_S = 0.07$, see Eq. (73). Actually, we find that $|S| < \sigma_S$ even with only the UNIT and BFB constraints imposed. Note that $S$ is mostly negative (positive) when $M_{H^\pm} > (<) M_A$. Specifically, we find that $S \simeq -1/4\pi (5/18) \simeq -0.02$ when $M_{H^\pm} - M_A = 0$ and $\gamma = \pi/2$. The $T$ parameter takes its value between $-0.02$ and $0.13$ which are given by the delimited range determined by $-0.02 < S < 0.05$, the strong correlation $\rho_{ST} = 0.92$ and $R^2_{95\%} = 5.99$, see Eqs. (72) and (73) and the lower-right plot in the left panel of Fig. 3. Incidentally, we observe that $T = 0$ when $M_{H^\pm} = M_A$ though it quickly deviates from 0 when $M_{H^\pm} \neq M_A$. In the right panel of Fig. 3, we show the correlations among the mass differences and the mixing angle $\gamma$ using the set $T_{\text{CPC}}$. We find that

$$|M_H - M_A|/\text{GeV} \lesssim 200 (100), \quad |M_{H^\pm} - M_H|/\text{GeV} \lesssim 200 (110),$$

$$|M_{H^\pm} - M_A|/\text{GeV} \lesssim 200 (110), \quad |\gamma| \lesssim 0.8 (0.14),$$

(89)

when $M_{H^\pm} \gtrsim 500 \text{ GeV} (1 \text{ TeV})$.

We show the correlations among the heavy Higgs-boson masses and the mixing angle $\gamma$ in the left panel of Fig. 4. Requiring the ELW constraint in addition to the UNIT⊕BFB ones, we find that $Z_1$ and $\gamma$ take values near to 0 and $Z_4$ and $Z_5$ positive ones more likely, see the right panel of Fig. 3. We find that the UNIT and BFB conditions combined with the ELW constraint restrict the quartic couplings as follows:

$$0.1 \lesssim Z_1 \lesssim 2.0, \quad 0 \lesssim Z_2 \lesssim 2.1, \quad -2.4 \lesssim Z_3 \lesssim 8.0, \quad -6.3 \lesssim Z_4 \lesssim 6.0,$$

$$-1.9 \lesssim Z_5 \lesssim 1.6, \quad -2.7 \lesssim Z_6 \lesssim 2.7, \quad -2.7 \lesssim Z_7 \lesssim 2.7.$$

(90)

C. Alignment of Yukawa couplings

Now, we have come to the point to address the alignment of Yukawa couplings. When we talk about the alignment of the Yukawa couplings in general 2HDMs, we imply: (i) the alignment of them in the flavor space and (ii) the alignment of the lightest Higgs-boson couplings to a pair of the SM fermions in the decoupling limit of $M_{H,A,H^\pm} \rightarrow \infty$. By (i), we precisely mean the assumption that the two Yukawa matrices of $y^f_1$ and $y^f_2$ are aligned in the flavor space or
\[ y_2^f = \zeta_f y_1^f, \text{ see Eq.}(45), \text{ which, in the CPC case, leads to} \]
\[
  g_{H_1,ff}^S = O_{\varphi_1} + \zeta_f O_{\varphi_2} = c_\gamma - \zeta_f s_\gamma, \tag{91}
\]

with \( f = u \) and \( d \) for the up- and down-type quarks, respectively, and \( f = e \) for the three charged leptons. Then, by (ii), one might mean
\[
  g_{H_1,ff}^S \to 1 \text{ as } M_{H, A, H^\pm} \to \infty. \tag{92}
\]

In Eq. (91), we note that the quantity \( c_\gamma \) is nothing but the coupling \( g_{H,VV} = O_{\varphi_1} = c_\gamma \) which is driven to take the SM value of 1 by the combined UNIT, BFB, and ELW constraints as \( M_{H, A, H^\pm} \) increases. Therefore, from Eq. (82), the Yukawa delay factor simplifies to \( \Delta_{H_1,ff} = |\zeta_f s_\gamma| \), and the alignment of the lightest Higgs-boson couplings to the SM fermions in the decoupling limit is delayed by the amount of \( |\zeta_f s_\gamma| \) which can not be ignored even when \( |s_\gamma| \ll 1 \) if \( |\zeta_f| \) is significantly larger than 1.

For a quantitative study, in addition to \( \mathcal{I}_{CPC}^* \) given by Eq. (84), we have added the following set of input parameters containing three real parameters:
\[
  \mathcal{I}_{CPC}^\zeta = \{ \zeta_u, \zeta_d, \zeta_e \}. \tag{93}
\]

In the left panel of Fig. 5, we show the correlations between each of the three alignment parameters \( \zeta_f = u, d, e \) and the mixing angle \( \gamma \) when the absolute value of the corresponding coupling \( g_{H_1,ff}^S \) is within 10\% range of the SM value of 1 or \( |g_{H_1,ff}^S - 1| < 0.1 \) and \( |g_{H_1,ff}^S + 1| < 0.1 \) for \( g_{H_1,ff}^S > 0 \) (red) and \( g_{H_1,ff}^S < 0 \) (blue), respectively. Scanning \( |\gamma| \leq \pi/2, g_{H_1,ff}^S \simeq 1 \) near \( \gamma = 0 \). At \( \gamma = \pm \pi/2, g_{H_1,ff}^S \) coupling takes the value of 1 when \( \zeta_f = \mp 1 \) (red). While if \( \zeta_f = \pm 1 \), we note that
\[
  g_{H_1,ff}^S \to -1 \text{ at } \gamma = \pm \pi/2 \text{ (blue)}. \]

In the right panel of Fig. 5, by the four lines, we show the correlations between \( \zeta_d \) and \( \zeta_e \) in the four conventional 2HDMs\(^{24}\) based on appropriately defined discrete \( Z_2 \) symmetries taking \( 1/100 < \zeta_0 = 1/t_\beta < 2 \), see Table I. We observe that both \( \zeta_0 \) and \( \zeta_\gamma \) are bounded only in the type-I 2HDM between 1/100 and 2. Otherwise, at least one of them is limitless in principle. Therefore, except the type-I 2HDM, \( g_{H_1,dd}^S \) and/or \( g_{H_1,ee}^S \) could be largely deviated from 1 in the decoupling limit even when \( \zeta_u \) is limited.

To concentrate on the alignment of the lightest Higgs-boson couplings to a pair of the SM fermions in the decoupling

\(^{24}\) The parameters \( \zeta_0 \) and \( \zeta_\gamma \) are completely uncorrelated in the general 2HDM based on the relation Eq. (45) as shown by the scattered black dots in the right panel of Fig. 5.
limit of $M_{H,A,H^\pm} \to \infty$ under the assumption of $y_2^f \propto y_1^f$ as in Eq. (45), we consider a simplified scenario in which the mixing angle $|\sin \gamma|$ is inversely proportional to $1/M_{H^\pm}^2$ reflecting the behavior of $|\sin \gamma| = |g_{HVV}|$ being suppressed by the quartic powers of the heavy Higgs-boson masses at leading order [141]. In the upper-left frame of Fig. 6, we show the scatter plot for $|\gamma|$ versus $M_{H^\pm}$ together with the three curves showing the cases of $\sin \gamma = (125 \text{ GeV}/M_{H^\pm})^2$ (black), $\sin \gamma = (200 \text{ GeV}/M_{H^\pm})^2$ (red), and $\sin \gamma = (350 \text{ GeV}/M_{H^\pm})^2$ (blue) from bottom to top. The input parameters are the same as in Fig. 4 and the combined UNIT $\oplus$ BFB $\oplus$ ELW$_{95\%}$ constraints are imposed. For illustration, we take the case of $\sin \gamma = (200 \text{ GeV}/M_{H^\pm})^2$. The coupling of the lightest Higgs boson $H_1$ to a pair of massive vector bosons is constrained by the precision LHC Higgs data [10]. We note that, for example, $\cos \gamma = g_{HVV} \gtrsim 0.95$ or $|\sin \gamma| = |g_{HVV}| \lesssim 0.3$ can be satisfied when $M_{H^\pm} \gtrsim 400$ GeV for this choice. We further assume that the masses of the heavy Higgs bosons of $H, A,$ and $H^\pm$ are degenerate. This assumption reflects the fact that the combined UNIT $\oplus$ BFB $\oplus$ ELW$_{95\%}$ constraints prefers quite degenerate heavy-Higgs bosons when they weigh more than about 400 GeV as shown in the left panel of Fig. 6. We dub this scenario SCN200 in which we precisely fix and vary the input parameters in the two sets of $T_{CPC}$ and $T_{CPC}^\perp$ as follows:

$$\text{SCN200} : \{M_h = M_{H_1} = 125.5 \text{ GeV}, M_H = M_A = M_{H^\pm} = [200..1500] \text{ GeV};$$

$$\sin \gamma = \pm(200 \text{ GeV}/M_{H^\pm})^2; Z_2 = [0..2], Z_3 = [-3..8], Z_7 = [-3..3]\}$$

$$\oplus \{\zeta_u = [1/100..2], \zeta_d = [-100..100], \zeta_c = [-100..100]\},$$

(94)

for the type II case. The Yukawa delay factor is given by

$$\Delta_{H_1ff}^{\text{SCN200}} = |\zeta_f| \frac{(200 \text{ GeV})^2}{M_{H^\pm}^2} \simeq |\zeta_f| \frac{Z_6 v^2}{M_{H^\pm}^2},$$

(95)

with $Z_6^{\text{SCN200}} \simeq 0.66$. Note that we use the approximation $Z_6 v^2 = (M_H^2 - M_h^2) c_s s_\gamma \simeq M_h^2 s_\gamma$ in the above equation.

In the upper-right frame of Fig. 6, we show the scatter plot of $g^S_{H_1\bar{u}u}$ versus $M_{H^\pm}$ taking SCN200 in which the upper limit on $|\zeta_u|$ from $R_b$ and $\epsilon_K$ is applied, see Eq. (77). We observe that the coupling $g^S_{H_1\bar{u}u}$ is within about

---

25 The choice of $\sin \gamma = (m_6/M_{H^\pm})^2$ is equivalent to fix $Z_6 = (M_H^2 - M_h^2) c_s s_\gamma \simeq M_h^2 s_\gamma$ in the above equation.
FIG. 6. (Upper Left) The same as in the lower-right plot in the left panel of Fig. 4 but for $|\gamma|$ versus $M_{H^\pm}$ with the UNIT$\oplus$BFB$\oplus$ELW constraints imposed. The three curves show the cases of $|\sin \gamma| = (125 \text{ GeV}/M_{H^\pm})^2$ (black), $|\sin \gamma| = (200 \text{ GeV}/M_{H^\pm})^2$ (red), and $|\sin \gamma| = (350 \text{ GeV}/M_{H^\pm})^2$ (blue) from bottom to top. (Upper Right) Scatter plot of $g_{H^\pm \bar{u}u}$ versus $M_{H^\pm}$ taking SCN200 in which the upper limit on $|\zeta_u|$ from $R_b$ and $\epsilon_K$ is applied, see Eq. (77). The blue (red) lines are for $\cos \gamma + (-)\zeta_u |\sin \gamma|$ for $\zeta_u = 2, 1, 0.2$ from the outermost lines to the magenta one which is for $g_{H^1 V V} = \cos \gamma$. (Lower Left) Scatter plot of $g_{H^\pm \bar{d}d}$ versus $M_{H^\pm}$ taking SCN200. The blue (red) lines are for $\cos \gamma + (-)\zeta_d |\sin \gamma|$ for $\zeta_d = 100, 50, 20, 10, 0.5$ from the outermost lines to the magenta one which is for $g_{H^1 V V} = \cos \gamma$. (Lower Right) The same as in the lower-left plot but for $g_{H^\pm \bar{e}e}$ versus $M_{H^\pm}$ with the lines for $\cos \gamma \pm \zeta_e |\sin \gamma|$ for $\zeta_e = 100, 50, 20, 10, 0.5$.

30% and 10% ranges of the SM value of 1 when $M_{H^\pm} > 500$ GeV and $M_{H^\pm} > 1$ TeV, respectively. As previously discussed, the alignment of the coupling $g_{H^\pm f f}^S$ is delayed by the amount of $\zeta_f \sin \gamma$ compared to the coupling $g_{H^1 V V}$.
and $g_{H_1 \bar{u} u}$ is most deviated from its SM value of 1 by the amount of

$$\Delta_{H_1 \bar{u} u}|_{SCN200,|\zeta_d|\leq 2} = |\zeta_u| \left( \frac{200 \text{ GeV}}{M_{H^\pm}} \right)^2 \leq 0.32 \left( \frac{500 \text{ GeV}}{M_{H^\pm}} \right)^2. \quad (96)$$

To make this point clear, we add the blue and red lines showing $g_{H_1 \bar{u} u}$ taking $\zeta_u = 0.2, 1$, and 2 and the magenta one showing $g_{H_1 V V}$. We indeed see that $g_{H_1 \bar{u} u}$ is most close to $g_{H_1 V V}$ when $\zeta_u = 0.2$ and the two lines taking $\zeta_u = 2$ provide the envelope which includes all the scattered points.\footnote{Note that the line segments for $\zeta_u = 2$ with $M_{H^\pm} \lesssim 500$ GeV are located outside the scattered region implying that they are excluded by the upper limit on $|\zeta_u|$ from $R_b$ and $\epsilon_K$.}

In the lower frames of Fig. 6, the scatter plots of $g_{H_1 \bar{d} d}^S$ versus $M_{H^\pm}$ (left) and $g_{H_1 \bar{e} e}^S$ versus $M_{H^\pm}$ (right) are shown. They are basically the same since $\zeta_d$ and $\zeta_e$ are varied in the same range of $[-100, 100]$. And the same arguments are applied as in the case of $g_{H_1 \bar{u} u}^S$; the lines with $\zeta_{d,e} = 0.5$ are most close to $g_{H_1 V V}$ among the blue and red lines and those with $\zeta_{d,e} = 100$ provide the envelopes which include all the scattered points. We see that $g_{H_1 \bar{d} d}^S$ and $g_{H_1 \bar{e} e}^S$ can be largely deviated from their SM values of 1 when $|\zeta_{d,e}|$ is large:

$$\Delta_{H_1 \bar{d} d, H_1 \bar{e} e}|_{SCN200,|\zeta_{d,e}|\leq 0.1, |\zeta_{d,e}|\leq 100} = |\zeta_{d,e}| \left( \frac{200 \text{ GeV}}{M_{H^\pm}} \right)^2 \lesssim 1.8 \left( \frac{1500 \text{ TeV}}{M_{H^\pm}} \right)^2. \quad (97)$$

Incidentally, we observe that the constraint on $|\zeta_e|$ from the flavor-changing $\tau$ decays into light leptons excludes the region with $|g_{H_1 \bar{e} e}^S| \gtrsim 60$ and $M_{H^\pm} \lesssim 250$ GeV which is not seen in the window chosen for the scatter plot of $g_{H_1 \bar{e} e}^S$ versus $M_{H^\pm}$ in Fig. 6 see Eq. (76).

Of course, the alignment parameters $\zeta_{d,e}$ are constrained by the precision LHC Higgs data. From the observation that the absolute values of the couplings of the SM-like $H_1$ to a pair of bottom quarks and tau leptons are required to be consistent with 1 within about 10\% at 1$\sigma$ level \footnote{The negative value of $g_{H_1 \bar{d} d}^S \sim -1$ is less preferred than the positive one $g_{H_1 \bar{d} d}^S \sim +1$ at the level of about 1.5$\sigma$ considering the $b$-quark loop contributions to the $H_1$ coupling to two gluons \cite{40}. While, for $g_{H_1 \bar{e} e}$, the current data precision is yet insufficient to tell its sign. In this work, we consider both signs for $g_{H_1 \bar{d} d}^S$ and $g_{H_1 \bar{e} e}^S$.}, one might have $|g_{H_1 \bar{d} d}^S\pm 1| \lesssim 0.1$ and $|g_{H_1 \bar{e} e}^S\pm 1| \lesssim 0.1$.\footnote{For the positive sign, the condition $|g_{H_1 \bar{d} d}^S\pm 1| \lesssim 0.1$ constrains $|\zeta_d| \lesssim 6$, see the red points in the left panel of Fig. 7.}
On the other hand $g_{H_{d,d}}^S \sim -1$ allows the larger values of $\zeta_d$ given by $\zeta_d = (1 + \cos \gamma)/\sin \gamma \simeq \pm 2M_{H^\pm}^2/(200 \text{ GeV})^2$, see the blue points in the left panel of Fig. [1]. In the same panel for $\zeta_d$ versus $M_{H^\pm}$, we also show the lower limit on $|\zeta_d|$ from $b \to s\gamma$ through the destructive interference by the magenta lines, see Eq. [80] and the lower-left panel of Fig. [1]. We observe that the two regions with $|g_{H_{d,d}}^S| + 1 < 0.1$ are mostly outside the band delimited by the two magenta lines implying that large values of $|\zeta_d|$ for $g_{H_{d,d}}^S \sim -1$ are hardly constrained by $b \to s\gamma$. For $g_{H_{t,t}}^S$, the same arguments are applied, see the right panel of Fig. [7]. Note that the constraints from the flavor-changing $\tau$ decays into light leptons given by Eq. (76) are too weak to affect those on $g_{H_{t,t}}^S$ by the precision LHC Higgs data.

Lastly, we comment on the wrong-sign alignment limit in the four types of conventional 2HDMs in which the $H_1$ couplings to the down-type quarks and/or those to the charged leptons are equal in strength but opposite in sign to the corresponding SM ones. The two couplings $g_{H_{d,d}}^S$ and $g_{H_{t,t}}^S$ are completely independent from each other in general 2HDM. But, in the conventional four types of 2HDMs, they are related. We observe that the couplings are given by either $\cos \gamma - \sin \gamma/t_\beta$ or $\cos \gamma + t_\beta \sin \gamma$ in any type of 2HDMs, see Table [1] In this case, $\cos \gamma - \sin \gamma/t_\beta = \pm 1$ for the $t_\beta$ value which makes $\cos \gamma + t_\beta \sin \gamma = \mp 1$. This implies that, independently of 2HDM type and regardless of the heavy Higgs-mass scale, all four types of 2HDMs could be viable against the LHC Higgs precision data in the wrong-sign alignment limit.

V. CONCLUSIONS

We have studied the alignment of Yukawa couplings in the framework of general 2HDMs identifying the lightest neutral Higgs boson as the 125 GeV one discovered at the LHC. We take the so-called Higgs basis [73, 74, 88–92] for the Higgs potential in which only one of the two doublets contains the non-vanishing vacuum expectation value v. For the Yukawa couplings, rather than invoking the Glashow-Weinberg condition [104] based on appropriately defined discrete $Z_3$ symmetries, we require the absence of tree-level FCNCs by assuming that the Yukawa matrices describing the couplings of the two Higgs doublets to the SM fermions are aligned in the flavor space [93–95].

For a numerical study, we further assume that the seven quartic couplings $Z_{i=1−7}$ appearing in the Higgs potential and the three alignment parameters $\zeta_f = u, d, e$ for Yukawa couplings are all real by anticipating that the impacts due to CP-violating phases of $Z_{5,6,7}$ and $\zeta_f$'s on the alignment of Yukawa couplings are redundant. In this case, in addition to the vev $v$ and masses of the SM fermions, the model can be fully described by specifying the following set of 11 free parameters:

$$\{M_h = M_{H^1} = 125.5 \text{ GeV}, M_H, M_A, M_{H^\pm}, \gamma, Z_2, Z_3, Z_7; \zeta_u, \zeta_d, \zeta_e\},$$

where $M_{h,H}$ (with $M_h < M_H$) and $M_A$ denote the masses of CP-even and CP-odd neutral Higgs bosons, respectively, and the mixing between the two CP-even neutral states is described by the angle $\gamma$. The quartic couplings $Z_{1,4,5,6}$ are determined in terms of $M_{h,H,A}, M_{H^\pm}, \gamma,$ and $v$. The quartic coupling $Z_3$ is related to the massive parameter $Y_2$ appearing in the Higgs potential through $Y_2 = M_{H^\pm}^2 - Z_3v^2/2$. On the other hand, the other quartic couplings $Z_2$ and $Z_7$ have no direct relevance to the masses and mixing of Higgs bosons. But, we observe that they are interrelated with the other five quartic couplings of $Z_{1,3,6}$ through the perturbative unitarity (UNIT) conditions and those for the Higgs potential to be bounded from below (BFB). We note that the UNIT and BFB conditions are basis-independent, i.e., the same in any basis [105]. Also considered are the constraints from the electroweak (EW) oblique corrections to the $S$ and $T$ parameters which are expressed in terms of the physical observable quantities of $M_{h,H,A}, M_{H^\pm}$, and $g_{H_{d,d}}$ which are again invariant under a change of basis [84]. We further consider the constraints on the alignment parameters $\zeta_f = u, d, e$ from flavor-changing $\tau$ decays, $R_b$, $\epsilon_K$, and the radiative $b \to s\gamma$ decay.

For the independent model parameters and the rephasing invariant combinations of CP-violating phases, among the several points already discussed in the literature, we highlight the following ones:

1. The general 2HDM potential can be fully specified with the masses of the charged and three neutral Higgs bosons, the orthogonal neutral-Higgs boson mixing matrix $O_{3 \times 3}$ and the three dimensionless quartic couplings of $Z_{2,3,7}$ in addition to the vev $v$.

2. For the CP phases, as far as the Higgs potential and the three complex alignment parameters for the Yukawa couplings are involved, the Lagrangians are invariant under the following phase rotations:

\begin{align}
H_2 &\to e^{+i\zeta} H_2; \\
Y_3 &\to Y_3 e^{-i\zeta}, \ Z_3 \to Z_3 e^{-2i\zeta}, \ Z_5 \to Z_5 e^{-i\zeta}, \ Z_6 \to Z_6 e^{-i\zeta}, \ Z_7 \to Z_7 e^{-i\zeta}; \\
\zeta_u &\to \zeta_u e^{+i\zeta}, \ \zeta_d \to \zeta_d e^{-i\zeta}, \ \zeta_e \to \zeta_e e^{-i\zeta},
\end{align}

(98)
which, taking account of the CP odd tadpole condition \( Y_3 + Z_6 \frac{v^3}{2} = 0 \), lead to the following five rephasing-invariant CPV phases:

\[
\text{Arg}[Z_0(Z_0^*)^{1/2}], \text{Arg}[Z_7(Z_7^*)^{1/2}], \text{Arg}[\zeta_u(Z_5^*)^{1/2}], \text{Arg}[\zeta_d(Z_5^*)^{1/2}], \text{and} \ \text{Arg}[\zeta_e(Z_5^*)^{1/2}],
\]

(99)

pivoting, for example, around the complex quartic coupling \( Z_5 \).

Incidentally, it is well known that the 3 alignment parameters are the same \( \zeta_u = \zeta_d = \zeta_e = 1/t_\beta \) in the type-I 2HDM. In this case, they cannot be significantly large than 1 since \( t_\beta \ll 1 \) leads to a non-perturbative top-quark Yukawa coupling and a Landau pole close to the TeV scale. Therefore, in the type-I model among the 4 conventional 2HDMs, all the Yukawa couplings of the lightest Higgs boson most quickly approach the corresponding SM values as the masses of the heavy neutral Higgs bosons increase and their decouplings are least delayed.

We further suggest the following points as the main results specifically pertinent to our analysis:

1. By scanning the heavy Higgs masses up to 1.5 TeV, we find that the UNIT and BFB conditions combined with the ELW constraint restrict the quartic couplings as follows:

\[
0.1 \lesssim Z_1 \lesssim 2.0, \quad 0 \lesssim Z_2 \lesssim 2.1, \quad -2.4 \lesssim Z_3 \lesssim 8.0, \quad -6.3 \lesssim Z_4 \lesssim 6.0, \\
-1.9 \lesssim Z_5 \lesssim 1.6, \quad -2.7 \lesssim Z_6 \lesssim 2.7, \quad -2.7 \lesssim Z_7 \lesssim 2.7.
\]

(100)

And, when \( M_{H^\pm} \gtrsim 500 \) GeV (1 TeV), we also find that

\[
|M_H - M_A|/\text{GeV} \lesssim 200 (100), \quad |M_{H^\pm} - M_H|/\text{GeV} \lesssim 200 (110), \\
|M_{H^\pm} - M_A|/\text{GeV} \lesssim 200 (110), \quad |\gamma| \lesssim 0.8 (0.14).
\]

(101)

2. As the masses of heavy Higgs bosons increase, compared to the \( g_{HVV} \) coupling of the lightest Higgs boson to a pair of massive vector bosons, the decoupling of the Yukawa couplings to the lightest Higgs boson is delayed by the amount of the Yukawa delay factor \( \Delta_{H,ff} = |\zeta_f|(1 - g_{HVV}^2)^{1/2} \) which is basis-independent and can be generally used even in the presence of CPV phases. Therefore, though \( g_{HVV} \) approaches its SM value of 1 very quickly as the masses of heavy Higgs bosons increase, the coupling of \( H_1 \) to a pair of fermions can significantly deviate from its SM value if \( |\zeta_f| \) is large. Note that \( |\zeta_u| \) is constrained to be small by \( R_b \) and \( \epsilon_K \), see Eq. [47]. While \( |\zeta_d| \) and \( |\zeta_e| \) are constrained to be small by the LHC precision Higgs data when the corresponding Yukawa couplings are with the similar strength and the same sign as the SM ones. But it could be large when the Yukawa coupling takes the wrong sign.

3. The wrong-sign alignment, in which the \( H_1 \) couplings to a pair of \( f \)-type fermions are equal in strength but opposite in sign to the corresponding SM ones, occurs when \( \zeta_f = (1 + \cos \gamma)/\sin \gamma \) independently of the heavy Higgs-boson masses. In the conventional four types of 2HDMs, \( \zeta_f = -t_\beta \) or \( 1/t_\beta \) and the Yukawa couplings are given by either \( \cos \gamma - \sin \gamma/t_\beta \) or \( \cos \gamma + t_\beta \sin \gamma \) in any type of 2HDMs. We observe that \( \cos \gamma - \sin \gamma/t_\beta = \mp 1 \) for the \( t_\beta \) value making \( \cos \gamma + t_\beta \sin \gamma = \pm 1 \) and any type of conventional 2HDMs is viable against the LHC Higgs precision data.

4. Last but not least, by combining with the upper limit on \( |\zeta_u| \) from \( R_b \) and \( \epsilon_K \), we derive the lower limit on \( |\zeta_d| \) independently of \( \zeta_u \) and \( \zeta_e \) when the non-SM contribution to \( b \to s\gamma \) is about two times of the SM one at the amplitude level.
