{ykashnitsky, skuznetsov}@hse.ru

Abstract. The paper addresses the graph classification problem and introduces a modification of the lazy associative classification method to efficiently handle intersections of graphs. Graph intersections are approximated with all common subgraphs up to a fixed size similarly to what is done with graphlet kernels. We explain the idea of the algorithm with a toy example and describe our experiments with a predictive toxicology dataset.

Keywords: graph classification, graphlets, formal concept analysis, pattern structures, lazy associative classification

1 Introduction

Classification methods for data given by graphs usually reduce initial graphs to numeric representation and then use standard classification approaches, like SVM [1] and Nearest neighbors with graph kernels [2], graph boosting [3], etc. By doing so, one usually constructs numeric attributes corresponding to subgraphs of initial graphs or computes graph kernels, which usually are also based on the number of common subgraphs of special type. In this paper, we suggest an approach based on weak classifiers in the form of association rules [4] applied in a “lazy” way: not all of the association rules are computed to avoid exponential explosion, but only those that are relevant to objects to be classified. Lazy classification is well studied experimentally [5], here we extend the approach to graphs and propose a uniform theoretical framework (based on pattern structures [6]) which can be applied to arbitrary kinds of descriptions. We show in a series of experiments with data from the Predictive Toxicology Challenge (PTC [7]) that our approach outperforms learning models based on SVM with graphlet kernel [8] and kNN with graphlet-based distance.

The rest of the paper is organized as follows. In Section 2, we give main definitions on labeled graphs, pattern structures, and lazy associative classification. In Section 3, we consider an example. In Section 4, we discuss the results of computational experiments on PTC dataset. In Section 5, we give the conclusion and discuss directions of further research.
2 Main definitions

In this section, we give the definitions of the main concepts used in the paper.

2.1 Labeled graphs and isomorphism

First, we recall some standard definitions related to labeled graphs, see e.g. [9][10].

Undirected graph is a pair $G = (V, E)$. Set $V$ is referred to as a set of nodes of a graph. Set $E = \{(v, u) \mid v, u \in V\} \cup E_0$, a set of unordered elements of $V$, is called a set of edges, and $E_0 \subseteq V$ — is a set of loops. If $E_0 = \emptyset$, then $G$ is called a graph without loops.

Graph $H = (V_H, E_H)$ is called a subgraph of graph $G = (V_G, E_G)$, if all nodes and edges of $H$ are at the same time nodes and edges of $G$ correspondingly, i.e. $V_H \subseteq V_G$ and $E_H \subseteq E_G$.

Graph $H = (V_H, E_H)$ is called an induced subgraph of graph $G = (V_G, E_G)$, if $H$ is a subgraph of $G$, and edges of $H$ are comprised of all edges of $G$ with both nodes belonging to $H$.

Given sets of nodes $V$, node labels $L_V$, edges $E$, and edge labels $L_E$, a labeled graph is defined by a quadruple $G = ((V, lv), (E, le))$ such that

- $lv \subseteq V \times L_V$ is the relation that associates nodes with labels, i.e., $lv$ is a set of pairs $(v_i, l_i)$ such that node $v_i$ has label $l_i$,
- $le \subseteq V \times V \times L_E$ is the relation that associates edges with labels, i.e., $le$ is a set of triples $(v_i, v_j, l_{ij})$ such that edge $(v_i, v_j)$ has label $l_{ij}$.

Example 1. A molecule structure can be represented by a labeled graph.

$$
\begin{array}{c}
\text{NH}_2 & \longrightarrow & \text{C}^3 & \longrightarrow & \text{CH}_3^2 \\
| & & & & \\
\text{OH}^5 & \bigg\uparrow & \bigg\downarrow & \bigg\uparrow & \text{Cl}^6
\end{array}
$$

Here $V = \{1, 2, 3, 4, 5, 6\}$, $E = \{(1, 2), (2, 3), (2, 4), (4, 5), (4, 6)\}$, $lv = \{(1, \text{NH}_2), (2, \text{CH}_3), (3, \text{C}), (4, \text{C}), (5, \text{OH}), (6, \text{Cl})\}$, $le = \{(1, 3, 1), (2, 3, 1), (3, 4, 2), (4, 5, 1), (4, 6, 1)\}$, and edge type 1 corresponds to a single bond (ex. $\text{HN}_2$) while edge type 2 — to a double bond (ex. $\text{C} = \text{C}$).

Definition 1. A labeled graph $G_1 = ((V_1, lv_1), (E_1, le_1))$ dominates a labeled graph $G_2 = ((V_2, lv_2), (E_2, le_2))$, or $G_2 \leq G_1$, if there exists a bijective mapping $\varphi: V_2 \rightarrow V_1$ such that it [11]:

- respects edges: $(v, w) \in E_2 \Rightarrow (\varphi(v), \varphi(w)) \in E_1$,
- fits under labels: $lv_2(v) \leq lv_1(\varphi(v))$, $le_2(v, w) \leq le_1(\varphi(v), \varphi(w))$.

Definition 2. Two labeled graphs $G_1$ and $G_2$ are called isomorphic ($G_1 \simeq G_2$) if $G_1 \leq G_2$ and $G_2 \leq G_1$. 
Example 2. \( G_1: \)
\[
\begin{array}{c}
\text{CH}_3^1 \xrightarrow{\text{C}} \text{C}^3 \xrightarrow{\text{OH}} \text{NH}_2^1 \xrightarrow{\text{C}} \text{C}^3 \xrightarrow{\text{Cl}} \\
\text{Cl}^1 & \text{NH}_2^6 & \text{CH}_3^1 & \text{OH}^6
\end{array}
\]

\( G_1 \simeq G_2 \) as \( \exists f: \{1, 2, 3, 4, 5, 6\} \to \{1, 2, 3, 4, 5, 6\} = (5, 6, 3, 4, 2, 1) \), satisfying Definitions 1 and 2.

**Definition 3.** An injective function \( f: V \to V' \) is called a subgraph isomorphism from \( G \) to \( G' \), if there exists a subgraph of \( G' \): \( S \subseteq G' \), such that \( f \) is a graph isomorphism from \( G \) to \( S \), or \( G \simeq S \).

\[
\begin{array}{c}
\text{CH}_3^1 \xrightarrow{\text{C}} \text{C}^3 \xrightarrow{\text{OH}} \text{NH}_2^1 \xrightarrow{\text{C}} \text{C}^3 \xrightarrow{\text{Cl}} \\
\text{C}^4 & \text{NH}_2^6 & \text{CH}_3^1 & \text{OH}^6
\end{array}
\]

Example 3. \( G_1: \)
\[
\begin{array}{c}
\text{CH}_3^1 \xrightarrow{\text{C}} \text{C}^3 \xrightarrow{\text{OH}} \text{NH}_2^1 \xrightarrow{\text{C}} \text{C}^3 \xrightarrow{\text{Cl}} \\
\text{C}^4 & \text{NH}_2^6 & \text{CH}_3^1 & \text{OH}^6
\end{array}
\]

\( G_1 \) is subgraph-isomorphic to \( G_2 \).

**Definition 4.** Given labeled graphs \( G_1 \) and \( G_2 \), a set \( G_1 \sqcap G_2 = \{ G \mid G \leq G_1, G_2, \ \forall G \subseteq G_1, G_2 \ G \not\geq G \} \) is called a set of maximal common subgraphs of graphs \( G_1 \) and \( G_2 \). We also refer to \( G_1 \sqcap G_2 \) as to intersection of graphs \( G_1 \) and \( G_2 \), and to \( \sqcap \) as to similarity operator defined on graphs \( \mathcal{GF} \). For sets of graphs \( \mathcal{G} = \{ G_1, \ldots, G_k \} \) and \( \mathcal{H} = \{ H_1, \ldots, H_n \} \) the similarity operator is defined in the following way:

\( \mathcal{G} \sqcap \mathcal{H} = \text{MAX} (\bigcup_{i,j} (\{ G_i \} \sqcap \{ H_j \})) \)

Example 4.
\[
\begin{array}{c}
\text{NH}_2 \xrightarrow{\text{C}} \text{C} \xrightarrow{\text{CH}_3} \text{Cl} \xrightarrow{\text{OH}} \\
\text{OH} & \text{Cl} & \text{NH}_2 & \text{OH}
\end{array}
\]

**Definition 5.** Given sets of labeled graphs \( \mathcal{G}_1 \) and \( \mathcal{G}_2 \), we say that a set of graphs \( \mathcal{G}_1 \) is subsumed by a set of graphs \( \mathcal{G}_2 \), or \( \mathcal{G}_1 \subseteq \mathcal{G}_2 \), if \( \mathcal{G}_1 \sqcap \mathcal{G}_2 = \mathcal{G}_1 \).

2.2 Graphlets

**Definition 6.** A labeled graph \( g \) is called a k-graphlet of a labeled graph \( G \) if \( g \) is a connected induced subgraph of graph \( G \) with \( k \) nodes.

**Definition 7.** A set of labeled graphs \( \mathcal{G}^k \) is called a k-graphlet representation of a labeled graph \( G \) if any \( g \in \mathcal{G} \) is a unique (up to subgraph isomorphism) k-graphlet of graph \( G \), i.e. \( \forall g \in \mathcal{G}^k \) graph \( g \) is a k-graphlet of \( G \), \( \forall g_1, g_2 \in \mathcal{G} \) one does not have \( g_1 \leq g_2 \).
Definition 8. **k-graphlet distribution**  
$k$-graphlet distribution of a labeled graph $G$ is the set $\{(g_i, n_i)\}$, where $g_i$ is a $k$-graphlet of $G$ and $n_i$ is the number of $k$-graphlets in $G$ isomorphic to $g_i$.

**Example 5.** $G_1$:

```
CH3
H
H
H
```

$G_2$:

```
OH
H
H
```

$G_1 = \{C - C = C, C - C - H, C = C - H, C - C - C\}$,

$G_2 = \{C - C = C, C - C - H, C = C - H, C - C - O, C = C - O, C - O - H\}$ – are 3-graphlet representations of graphs $G_1$ and $G_2$ correspondingly (with benzene rings comprised of carbon molecules C). 3-graphlet distributions of graphs $G_1$ and $G_2$ are given in Table 1.

**Table 1.** 3-graphlet distributions of graphs $G_1$ and $G_2$ (benzene rings are comprised of carbon molecules C).

| 3-graphlets | $G_1$ | $G_2$ |
|-------------|-------|-------|
| $C - C = C$ | 7     | 6     |
| $C - C - H$ | 8     | 4     |
| $C = C - H$ | 5     | 4     |
| $C - C - O$ | 0     | 2     |
| $C = C - O$ | 0     | 2     |
| $C - O - H$ | 0     | 2     |
| $C - C - C$ | 1     | 0     |

**Example 6.** Figure [1] shows a labeled graph which approximates the molecule structure of one of the molecules from Predictive Toxicology Challenge dataset [1] (№267 from the test set). 4-graphlet representation of this graph is given in Figure [2].

Graphlets were introduced in biomedicine and are used to compare real cellular networks with their models. It is easy to demonstrate that two networks are different by simply showing a short list of properties in which they differ. It is much harder to show that two networks are similar, as it requires demonstrating their similarity in all of their exponentially many properties [12].

---

1 [http://www.predictive-toxicology.org/ptc/]
Fig. 1. Test molecule 267 from PTC dataset. Red ball depicts a molecule of hydrogen (H), yellow – carbon (C), coral – oxygen (O).

Graphlet distribution serves as a measure of network local structure agreement and was shown to express more structural information than other metrics such as centrality, local clustering coefficient, degree distribution etc. In [12], they considered all 30 combinations of graphlets with 2, 3, 4 and 5 nodes shown in Figure 3.

2.3 Pattern structures

Pattern structures are natural extension of ideas proposed in Formal Concept Analysis [13], [6].

Definition 9. Let \( G \) be a set (of objects), let \((D, \sqcap)\) be a meet-semi-lattice (of all possible object descriptions) and let \( \delta : G \to D \) be a mapping between objects and descriptions. Set \( \delta(G) := \{ \delta(g) | g \in G \} \) generates a complete subsemilattice \((D_\delta, \sqcap)\) of \((D, \sqcap)\), if every subset \( X \) of \( \delta(G) \) has infimum \( \sqcap X \) in \((D, \sqcap)\).

Pattern structure is a triple \((G, D, \delta)\), where \( D = (D, \sqcap) \), provided that the set \( \delta(G) := \{ \delta(g) | g \in G \} \) generates a complete subsemilattice \((D_\delta, \sqcap)\) [6,11].

Definition 10. Patterns are elements of \( D \). Patterns are naturally ordered by subsumption relation \( \sqsubseteq \): given \( c, d \in D \) one has \( c \sqsubseteq d \iff c \sqcap d = c \). Operation \( \sqcap \) is also called a similarity operation. A pattern structure \((G, D, \delta)\) gives rise to the following derivation operators \((\cdot)\)°:

\[
A^\circ = \bigcap_{g \in A} \delta(g) \quad \text{for } A \in G,
\]

\[
d^\circ = \{ g \in G | d \sqsubseteq \delta(g) \} \quad \text{for } d \in (D, \sqcap).
\]

\(^2\) https://parasol.tamu.edu/dreu2013/OLEary
Fig. 2. 4-graphlet representation of test molecule 267 from PTC dataset. Red ball depicts a molecule of hydrogen (H), yellow – carbon (C), coral – oxygen (O).

Pairs \((A, d)\) satisfying \(A \subseteq G\), \(d \in \mathcal{D}\), \(A \cdot d = d\), and \(A = d \cdot d\) are called pattern concepts of \((G, \mathcal{D}, \delta)\).

Example 7. Let \(\{1, 2, 3\}\) be a set of objects, \(\{G_1, G_2, G_3\}\) – be a set of their descriptions (i.e., graph representations):

\[
G_1 : \quad \begin{array}{c}
    \text{CH}_3 - C & \text{NH}_2 \\
    \text{NH}_2 & \text{NH}_2
\end{array}
\quad G_2 : \quad \begin{array}{c}
    \text{NH}_2 - C & \text{OH} \\
    \text{CH}_3 & \text{C}
\end{array}
\quad G_3 : \quad \begin{array}{c}
    \text{NH}_2 - C & \text{OH} \\
    \text{NH}_2 & \text{Cl}
\end{array}
\]

\(\mathcal{D}\) is the set of all sets of labeled graphs, \(\sqcap\) is a graph intersection operator (Definition 4). \(\mathcal{D} = (\mathcal{D}, \sqcap)\). A set of objects (graphs) \(\{1, 2, 3\}\), their “descriptions” (i.e. graphs themselves) \(\mathcal{D} = \{G_1, G_2, G_3\}\) \((\delta(i) = G_i, i = 1, \ldots, 3)\), and similarity operator \(\sqcap\) comprises a pattern structure \((\{1, 2, 3\}, \mathcal{D}, \delta)\).

\(\{1, 2, 3\} \cdot = \{\text{NH}_2 - C = C\}\), because \(\{\text{NH}_2 - C = C\}\) is the only graph, subgraph-isomorphic to all three graphs 1, 2, and 3. Likewise, \(\{\text{CH}_3 - C = C\} \cdot = \{1, 2\}\), because graphs 1, 2, and 3 subsume graph \(\{\text{NH}_2 - C = C\}\).

\(\{1, 2\} \cdot = \{\text{CH}_3 - C = C - \text{NH}_2\}\), because \(\{\text{CH}_3 - C = C - \text{NH}_2\}\) is a graph, subgraph-isomorphic to 1, and 2, but not to graph 3. Likewise, \(\{\text{CH}_3 - C = C - \text{NH}_2\} \cdot = \{1, 2\}\), because only graphs 1, and 2 subsume graph \(\{\text{CH}_3 - C = C - \text{NH}_2\}\), but graph 3 does not.
Fig. 3. A diagram displaying all 30 possible graphlets with 2, 3, 4, and 5 nodes.

Here is the set of all pattern concepts for this pattern structure:

\[
\left\{ \left( \{1, 2, 3\} , \begin{array}{c} \text{NH} \\ \text{C} \end{array} \right) , \left( \{1, 2\} , \begin{array}{c} \text{CH} \\ \text{NH} \end{array} \right) , \left( \{1, 3\} , \begin{array}{c} \text{NH} \\ \text{CH} \end{array} \right) , \left( \{2, 3\} , \begin{array}{c} \text{NH} \\ \text{C} \end{array} \right) , (1, \{G_1\}) , (2, \{G_2\}) , (3, \{G_3\}) , (\emptyset, \{G_1, G_2, G_3\}) \right\}
\]

For some pattern structures (e.g., for the pattern structures on sets of graphs with labeled nodes) even computing subsumption of patterns may be NP-hard. Hence, for practical situations one needs approximation tools, which would replace the patterns with simpler ones, even if that results in some loss of information. To this end, we use a contractive monotone and idempotent mapping \( \psi : D \rightarrow D \) that replaces each pattern \( d \in D \) by \( \psi(d) \) such that the pattern structure \( (G, D, \delta) \) is replaced by \( (G, D, \psi \circ \delta) \). Under some natural algebraic requirements that hold for all natural projections in particular pattern structures we studied in applications, see [14], the meet operation \( \cap \) is preserved: \( \psi(X \cap Y) = \psi(X) \cap \psi(Y) \). This property of a projection allows one to relate premises in the original representation with those approximated by a projection. In this paper, we utilize projections to introduce graphlet-based classification rules.
2.4 Lazy associative classification

Consider a binary classification problem with a set of positive examples \( G_+ \), negative examples \( G_- \), test examples \( G_{\text{test}} \), and a pattern structure \((G_+ \cup G_-, \mathcal{D}, \delta)\) defined on the training set.

**Definition 11.** A pattern \( h \in \mathcal{D} \) is a **positive premise** iff \[ h \cap G_- = \emptyset \text{ and } \exists A \subseteq G_+ : h \sqsubseteq A \]

A positive premise is a subset of the *least general generalization* of descriptions of positive examples, which is not contained in (does not cover) any negative example. A **negative premise** is defined similarly. Various classification schemes using premises are possible, as an example consider the following simplest scheme from [6]: if the description \( \delta(g) \) of an undetermined example \( g \) contains a positive premise \( h \), i.e., \( h \sqsubseteq \delta(g) \), then \( g \) is classified positively. Negative classifications are defined similarly. If \( \delta(g) \) contains premises of both signs, or if \( \delta(g) \) contains no premise at all, then the classification is contradictory or undetermined, respectively, and some probabilistic techniques allowing for a certain tolerance should be applied.

**Definition 12.** Class association rule (CAR) [5] for a binary classification problem is an association rule in a form \( h \rightarrow \{+, -\} \), where \( h \) is a positive or negative premise, respectively.

The definition means that for a binary graph classification problem, for instance, we can mine classification association rules in a form \( \{g_i\} \rightarrow \{+, -\} \), i.e. if a test graph subsumes a subgraph \( g_i \), that is common only to positive (negative) train examples, it is therefore classified as positive (negative). We elaborate this idea in the next subsection. As there might be lots of such CARs, we might come up with a single classification rule taking into account these CARs. For instance, we can count all positive and negative CARs for each test object and classify it with a majority voting procedure. Of course, the idea is easily generalized to multi-label classification problem. The described classification schemes are explored in [5].

Another advantage of the lazy classification framework is its obvious parallelization. Suppose there are \( K \) processors. If we consider classification of an unlabeled object we can divide the training set into \( K \) separate subsets. Then, for each subset we perform intersections between the labeled objects with the unlabeled one to be classified. After all unfalsified intersections are found we can go on to the classification phase which involves voting based on those intersections.

2.5 Graphlet-based lazy associative classification

In this subsection, we combine the ideas of pattern structures and their projections, graphlets, and lazy associative classification, and introduce our algorithm. First, we recall the definition of \( k \)-projection producing all graphs with less than or equal to \( k \) nodes.
Definition 13. Given a graph pattern structure \((G, D, \delta)\), we call \(\psi_k(G) = \{H_i = ((V_i, lv_i), (E_i, le_i)) \mid H_i \leq G, |V_i| \leq k\}\) a \(k\)-projection, defined for graph descriptions \(G\).

Obviously, this operator is a projection, i.e. contractive, monotone, and idempotent function.

Definition 14. Given a graph pattern structure \((G, D, \delta)\), \(k\)-graphlet derivation operator \(\delta_k = \bigcup_{1 \leq l \leq k} \psi_l \circ \delta\) takes an object \(g\) described by graph \(G\) and produces all \(l\)-graphlets of \(G\) for \(l = 1, \ldots, k\).

Example 8. For object 1 with “graph description” \(G_1\) from example 5 \(\delta_3(1)\) is the set of all 1-, 2-, and 3-graphlets of graph 1:
\[
\delta_3(1) = \{C, H, C - C, C = C, C - H, C - C = C, C - C - H, C = C - H, C - C - C\}.
\]

To clarify, here \(\delta(1) = \{G_1\}, \delta_3(1) = \psi_3(\delta(1)) = \psi_3(G_1) = \{H_i = ((V_i, lv_i), (E_i, le_i)) \mid H_i \leq G_1, |V_i| \leq 3\}\).

Definition 15. Given \(k\)-graphlet representations \(G_1^k\) and \(G_2^k\) of labeled graphs \(G_1\) and \(G_2\), the intersection \(G_1^k \cap_k G_2^k\) is called \(k\)-graphlet intersection of \(G_1\) and \(G_2\). The \(\cap_k\) operator is further called \(k\)-graphlet similarity operator.

Example 9. For graphs 1 and 2 with “graph descriptions” \(G_1\) and \(G_2\) from example \(G_1 \cap_3 G_2 = \{C, H, C - C, C = C, C - H, C - C = C, C - C - H, C = C - H\}\)
is the set of all common 1-, 2-, and 3-graphlets of graphs 1 and 2.

Here are the main steps of our algorithm:

1. All \(k\)-graphlet intersections of test examples and positive train examples are computed: \(h_+ = G_{tr} \cap_k G_+\);
2. Each intersection \(h_+\) is tested on subsumption by negative train examples.
   If some of them subsumes \(h_+\), then this intersection is falsified. Otherwise, \(h_+\) gives a vote for positive classification of the test example \(G_{tr}\);
3. The same procedure is done for each intersection of \(G_{tr}\) with negative examples;
4. Test example \(G_{tr}\) is classified according to the weighted majority rule where each unfalsified intersection is given a weight equal to its cardinality.

3 A toy example

We illustrate the principle of our method with a toy example. Let us consider the following training and test sets comprised of molecular descriptions of toxic (\(G_1 - G_4\)) and non-toxic (\(G_5 - G_7\)) chemical compounds. The task is to build a discriminative classifier able to determine whether the objects from the test set (\(G_8 - G_{11}\)) are toxic or not. The main steps of the algorithm, described in the previous section, are briefly illustrated with tables 2 and 3. First, we build 3-graphlet intersections of test and train examples (we use only graphlets with 3 nodes for the purpose of illustration). Then, a “+” or “−” sign with
cardinality of intersection is put in table 3 if this intersection is not subsumed by any example of the opposite class. Otherwise, the counter-example subsuming this intersection is given.

Positive examples:

\[ G_1 : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{B} \\
\text{D} \quad \text{D}
\end{array}
\]
\[ G_2 : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{B} \\
\text{B} \quad \text{D}
\end{array}
\]
\[ G_3 : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{B} \\
\text{A} \quad \text{E}
\end{array}
\]
\[ G_4 : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{B} \\
\text{E} \quad \text{E}
\end{array}
\]

Negative examples:

\[ G_5 : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{D} \\
\text{D} \quad \text{D}
\end{array}
\]
\[ G_6 : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{E} \\
\text{B} \quad \text{D}
\end{array}
\]
\[ G_7 : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{D} \\
\text{B} \quad \text{E}
\end{array}
\]

Test examples:

\[ G_8 : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{B} \\
\text{D} \quad \text{E}
\end{array}
\]
\[ G_9 : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{D} \\
\text{B} \quad \text{E}
\end{array}
\]
\[ G_{10} : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{D} \\
\text{D} \quad \text{E}
\end{array}
\]
\[ G_{11} : \]
\[
\begin{array}{c}
A \quad \text{C} \quad \text{B} \\
\text{A} \quad \text{D}
\end{array}
\]

3-graphlet intersections of train and test examples are given in Table 2. For instance, graphs \( G_1 \) and \( G_8 \) have 4 common 3-graphlets: A–C–B, A–C=C, B–C=C, and C=C–D. In this simple case, we do not differentiate between a single and a double bond (e.g., ACC here stands for A–C=C without ambiguity).

Further, table 3 summarizes the procedure. For instance, a ’+4’ sign for graphs \( G_1 \) and \( G_8 \) means that all common 3-graphlets of \( G_1 \) and \( G_8 \) (i.e., A–C–B, A–C=C, B–C=C, and C=C–D) are not subgraph-isomorphic to any of the negative examples \( G_5 - G_7 \) altogether at the same time. Thus, this intersection “gives a vote” of weight 4 (the cardinality of the mentioned set of graphlets) for positive classification of \( G_8 \). On the contrary, all common 3-graphlets of \( G_4 \) and \( G_8 \) (A–C=C, B–C=C, and C=C–E) are altogether subgraph-isomorphic to
negative example $G_6$, therefore, the intersection of $G_4$ and $G_8$ doesn’t “give a vote” for positive classification of $G_8$.

4 Experiments

The proposed algorithm was tested with 2001 Predictive Toxicology Challenge dataset in comparison with SVM with graphlet kernel and k-Nearest-Neighbor with graphlet-based Hamming distance. SVM classifiers are considered to be good benchmarks for graph classification problem [8]. We implemented a Scikit-learn [15] version of Support Vector Classifier with graphlet kernel and graphlets having up to 5 nodes. We also adopted a k-Nearest-Neighbor for graph classification problem by defining a Hamming distance between two graphs (0 if two objects have a certain graphlet in common, 1 otherwise). For instance, for two graphs from example 5 in case of graphlets with up to 3 nodes this distance is equal to 7 ($G_1$ subsumes graphlet $C - C - C$ not subsumed by $G_2$, while $G_2$...
subsumes graphlets \( \{ O, C - O, O - H, C - C - O, C = C - O, C - O - H \} \) not subsumed by \( G_1 \).

The training set is comprised of 314 molecular graphs of chemical compounds with indication of whether a compound is toxic or not for a particular sex and species group out of four possible groups: \{ mice, rats \} \times \{ male, female \}. We selected all graphs with the number of nodes from 5 to 20. Thus, 4 separate sets were built for male rats (MR, 142 examples, 68 are toxic for male rats, 74 are non-toxic), male mice (MM, 151 examples, 64 are positive, 87 are negative), (FR, 137 examples, 49 are positive, 88 are negative) and female mice (FM, 147 examples, 70 are positive, 77 are negative).

We run 5-fold cross-validation for each group (MR, MM, FR, FM) and compare average classification metrics such as accuracy, precision, recall and F-measure for each fold. The results are presented in tables 4, 5, 7, and 6. “GLAC” stands for “Graphlet-based lazy associative classification”, “SVM” here denotes “Support Vector Machine with graphlet kernel” “kNN” here stands for a k-Nearest-Neighbor classifier with Hamming distance. The parameters for SVM and kNN classifiers were tuned through the process of GridSearch cross-validation. The ‘K nodes’ parameter determines the maximum number of nodes in graphlet representation of graphs, i.e. when it is equal to 4, all graph are approximated with their 4-graphlet representation, or all unique (in the sense of isomorphism) graphlets with up to 4 nodes.

### Table 4. Experimental results for the male rats group.

| K nodes | Accuracy | Precision | Recall | F-score | Time (sec.) |
|---------|----------|-----------|--------|---------|-------------|
| GLAC    |          |           |        |         |             |
| 2       | 0.02     | 0.01      | 0.33   | 0.01    | 5.78        |
| 3       | 0.68     | 0.57      | 0.62   | 0.59    | 17.40       |
| 4       | 0.59     | 0.83      | 0.68   | 0.75    | 65.72       |
| 5       | 0.55     | 0.7       | 0.62   | 0.66    | 196.03      |
| SVM     |          |           |        |         |             |
| 2       | 0.45     | 0.15      | 0.33   | 0.21    | 1.54        |
| 3       | 0.52     | 0.35      | 0.35   | 0.35    | 9.03        |
| 4       | 0.41     | 0.27      | 0.28   | 0.28    | 61.31       |
| 5       | 0.36     | 0.24      | 0.25   | 0.24    | 295.89      |
| kNN     |          |           |        |         |             |
| 2       | 0.45     | 0.15      | 0.33   | 0.21    | 3.35        |
| 3       | 0.34     | 0.21      | 0.23   | 0.22    | 15.75       |
| 4       | 0.48     | 0.31      | 0.32   | 0.31    | 73.38       |
| 5       | 0.45     | 0.30      | 0.31   | 0.30    | 211.58      |

As we can observe, graphlet-based lazy associative classification is reasonable with at least 3-graphlet descriptions. In case of 2-graphlet descriptions the algorithm practically always refuses to classify test objects, because 2-graphlet intersections of positive and test objects are falsified by negative objects and vice versa. But 3-graphlet descriptions are optimal for this method as the model is overfitted in case of 4- and 5-graphlet descriptions.

5 Conclusion

In this paper, we have proposed an approach to graph classification based on the combination of graphlets, pattern structures and lazy classification. Pattern structures give a unified approach to defining closed descriptions and classifiers (premises) for arbitrary types of descriptions. The key principle of lazy classification is that one does not have to produce the whole set of classification rules whatever they are. Instead, one generates those rules that allow one to classify current test object. The framework favors the complex structure of objects as soon as the algorithm does not require a training phase.

We have carried out a number of experiments in molecule classification within the proposed lazy classification framework. We compared classification performance of our method and SVM with graphlet kernel and KNN with graphlet-based distance. The reason for such a choice is that SVM classifiers are considered to be good benchmarks for graph classification problem, while kNN is a famous lazy classification method.

In our experiments graphlet-based lazy classification - following the same learning curve as the other methods - shows better classification performance compared to the classical methods in case of molecule toxicity prediction problem. Further, we plan to investigate the overfitting problem for our algorithm, in particular, the dependency of classification metrics on the number of considered nodes in graphlets. Other types of descriptions and a parallel version of our algorithm are also promising directions of study.
